CUK - H06737 - 178 RP309

tyranny of examinations, many schools feel the need to offer their pupils the chance of measuring their standards of achievement by examinations of one kind or another. The teachers who believe that some kind of stimulus is needed are encouraged by those parents who refuse to keep their children at school beyond the age of fifteen unless an examination is in prospect. Many of the special courses in the modern schools are based on the syllabuses of the General Certificate of Education, although not usually on the academic subjects of the General Certificate. Nevertheless, it is generally agreed that the General Certificate of Education is an unsuitable examination for most modern school pupils. The examinations of a few professional bodies like the Royal Society of Arts or Pitman's College are suitable for those engaged in studies of a mainly vocational kind; but on the whole these are regarded as being too specialized.

In a recent circular* the Minister of Education has made it clear that he does not favour a new general examination for modern schools, nor the use of external examinations for any pupil under the age of sixteen. This does not mean that the Minister is against examinations in modern schools. He is rightly anxious that the interests of the majority are not sacrificed to the needs of the few. Experiments by groups of schools organizing their own examinations would be welcomed so long as the schools retain control over their own syllabuses. Here, surely, is an opportunity for university institutes of education to give a lead. Why should not regional panels representing academic staffs of modern schools, staffs of university education departments and training colleges and local industrialists be formed to devise courses and examinations suitable for the needs of secondary modern pupils, relevant to the requirements of local industries and acceptable to parents and employers? These could be related to the preliminary courses of further education institutions as well as the early stages of achievement required for the Duke of Edinburgh's Award in rescue and public service, training, expedition, pursuits and fitness, the details of which have recently been announced. These courses and examinations could form the bridge both between school and employment and the leisure-time pursuits of the schoolboy and those of the developing adolescent in industry and commerce. Such a proposal would do much to develop local pride in the modern school. Most important of all, it would give the modern schools something which so many of them appear to lack at the moment—faith in their ability to produce good citizens in an industrial society. For encouragement they should examine those schemes which are already in being in different parts of the country. They should also remember that discerning employers already prefer to select their apprentices from successful modern school children rather than from grammar school 'failures'.

SCIENCE AND MODERN LIFE

Science and Modern Life

By Sir E. John Russell. (Beckly Lecture for 1955.) Pp. iv+101. (London: Epworth Press, 1955.) 6*s*. 6*d*. net.

In this Beckly Lecture, presumably somewhat extended in published form, Sir John Russell has indicated some of the more difficult problems raised by the ever-increasing force of the impact of science and technology on our social life. Incidentally, he has touched on many other matters, currently discussed at several ranges of temperature. Through his long, very active life as chemist, agriculturist and man of affairs, he has travelled widely, met all kinds and conditions of men and, endowed with a sympathetic outlook, faculty of keen observation and retentive memory, has produced a most interesting, kaleidoscopic survey.

The large number of topics touched upon in a hundred short pages necessarily involves a cursory treatment of most of them, and no deep analysis of any one subject could be attempted. Nevertheless, the book is highly stimulating and can be warmly recommended to the general reader. At the outset the co-existence of a scientific and religious discipline in some early pioneers is noted, and at the end Sir John, for almost the first time in these pages, allows himself to express a definite personal view that hope for the future lies in the co-operation of science and religion in solving the serious and complex problems of human relationships. Again, he says "that the solution [of new social and ethical problems] lies in a more effective infusion into our lives of the spirit of Christianity". Taken quite literally the statement is unexceptionable, and the context shows that the emphasis is on the ethical system rather than on the dogmatic framework. An important question remains begged; but the author, as a scientist, probably wishes to see his own house in order and feels no urge to inquire into the lag period, differing according to the circumstances, in bringing religious dogma into line with knowledge of the natural world. Apart from this moral of the story, the bulk of the work is essentially a factual record, and only here and there will occasion be found to cavil at the statements made.

Many readers will think that the trend of the section on pp. 51–56 goes quite the wrong way. Contrary to the author's suggestion (p. 52), there seems no good reason to suppose that the existence of heredity involves the gradual deterioration of the race as an inevitable consequence. As Calverley said in another connexion, "we're not as pussies are", and surely we have more control over our destiny as a race than, say, carnation cuttings have over theirs. Admittedly it is hard to get a yard-stick in these matters; but the statements in regard to the quality of university students are contrary to the views of some teachers of long experience. In the opinion of many of us, the average calibre of present-day students is certainly no less than that of their predecessors. Nor is there any evidence of the shortening of the range of brilliance so as to produce a dead level of mediocrity.

A feature of the work which will be much appreciated is the references, which are valuable indications for further reading over a wide field.

In this little book there is sunshine and gloom, and perhaps rather more of the latter for the simple reason that the author has focused his attention chiefly on problems and difficulties. We should be most grateful for such a sincere expression of the thoughts and reactions of so eminent a scientist and administrator.

ROBERT ROBINSON

MODERN PHYSICS WITHOUT TEARS

Atoms and the Universe

An Account of Modern Views on the Structure of Matter and the Universe. By Prof. G. O. Jones, Prof. J. Rotblat and G. J. Whitrow. Pp. 254+31 plates. (London: Eyre and Spottiswoode (Publishers), Ltd., 1956.) 25*s.* net.

IN this book the authors have attempted an overall review of modern discoveries and ideas in physics and astronomy within the space of 250 pages. Though, in doing this, they have, as they say, had "to abandon one of the main characteristics of scientific method—its insistence on rigour in argument and explanation", the result is almost completely successful in giving the reader a convincing sketch-picture of recent achievements.

With my own specialized knowledge of atomic physics, I found the astronomical part of the book of greatest interest. This is extremely concise and close-packed with interesting facts and speculations. It is beautifully illustrated with a number of plates of planets and nebulæ. But it is quite possible to imagine an astronomer who would be more interested in the part of the book dealing with atomic physics.

The only unsatisfactory part of the book is that in which the authors try to explain very briefly the ideas of relativity and quantum mechanics. This was probably an impossible task; but I think that more than two pages might have been devoted to experiments and illustrations of the wave-properties of matter and that the considerations of the level-structure of atomic and molecular systems might have been amplified, since a great deal of the astronomical section involves knowledge of spectra and the shifting of spectral lines by the Doppler effect (beautifully illustrated, it is true, but nowhere explained).

But it would be surprising if one could not pick holes in such a book. It is very pleasant to see that the authors have found it possible to describe in simple, non-mathematical terms so much of modern physics and astronomy. There must, of course, be a limit to such an attempt. Quantum and general relativity ideas are not only less familiar than classical ideas, they are also more difficult to understand and to deal with. The Uncertainty Principle sets a limit to one's knowledge, especially to the knowledge one can express in familiar terms. Fortunately, much of physics is still 'classical', if we can tack on such fundamentally non-classical, but easily understood, developments as radioactivity. Astronomy is nearly 'classical' if one accepts the Einstein equivalence of mass and energy, and the motions of fundamental particles are mostly 'classical' until we have to deal with interactions, which involve various diffraction effects. Thus there is a large section of modern physics which can be visualized in more or less classical terms, and the authors have rightly exploited this. Indeed, the ordinary physicist should do just this in his experimental work—he should try to think things out for himself as simply as possible, if sometimes inaccurately, rather than wait for the pure mathematician to tell him all the answers.

I am sure that many of the simplified discussions in the book will prove of interest even to the professional in physics and astronomy. As a review of modern discoveries in these subjects, the book is excellent for the scientist who does not specialize in them. It certainly should be read by all students of physics or applied mathematics as a supplement to their formal text-books, and it can also be strongly recommended to the layman who has some background knowledge of physics.

H. W. B. SKINNER

CRYSTAL PHYSICS

Handbuch der Physik

Herausgegeben von S. Flugge. Band 7, Teil 1: Kristallphysik, 1. Pp. vii+687. (Berlin: Springer-Verlag, 1955.) 122.50 D. marks.

THIS book is one of the first parts to appear of the new "Handbuch der Physik"; together with Part 2 of Vol. 7, it will form a complete work on crystal physics. The necessity for two parts gives some idea of the importance of crystal physics to the other main branches of science. The book contains four sections: crystallography (102 pp., by H. Jagodzinski, in German); theory of the mechanical and thermal properties of crystals (221 pp., by G. Leibfried, in German); the specific heat of crystals (58 pp., by M. Blackman, in English); and the theory of lattice faults (283 pp., by A. Seeger, in German). There are two useful indexes giving the German–English and English–German equivalents of a large selection of technical terms. There is no name index.

Each paper is well documented by reference to works in German and English; relatively, there are few references to work in other languages. It is probable that these references will prove to be the most important part of the book, for in the space available some of the sections are rather cramped. Consider the section by Jagodzinski, for example; in one hundred pages it covers formal crystal symmetry, the relation between symmetry and physical properties, descriptions of some basic structures, and the relation between crystal structure and physical properties. The author has introduced several new ideas into the presentation of space-group theory, and I am particularly pleased to see that his treatment does not take the existence of the Bravais space-lattices for granted. On the other hand, there is a section entitled "Ein Weg zür luckenlosen Ableitung der 230 Raumgruppen" which disposes of the subject in four pages of text.

There is, unfortunately, a small degree of overlapping with the next section, by Leibfried, whose main object, however, is to give a general review of the theory of interatomic forces rather than to describe their effects in particular crystals. It is rather heavily mathematical, descending only occasionally to compare theoretical results with experiment, and omitting completely any descriptions of experimental methods. Experimentalists, however, should find this section useful in showing what type of experimental result is most useful in the general theoretical development of the subject.

Leibfried's and Blackman's sections again overlap appreciably; both discuss the Debye theory in some detail and its modification by Born and others. Blackman's account provides a very useful summary of the present state of the subject of the specific heats, and is of value to both theoretical and experimental physicists. It shows what an important part the characteristic temperature plays and also, unfortunately, what a complicated concept it has now become.

The final section, on lattice faults, is likely to be the least useful to the English-speaking world, solely because there are so many papers in English on the subject; about four-fifths of the papers in the bibliography are in English. For this same reason, it should be valuable to the Germans, and may give some incentive to them to apply their analytical powers to a new, fascinating and practically important branch of crystal physics.

The general impression remains of a thoroughly competent and able piece of work, rather ponderous perhaps, but of the general style that one expects in an encyclopædia. H. LIPSON

THE WREN IN BRITAIN

The Wren

By Edward A. Armstrong. (The New Naturalist Series.) Pp. viii+312+8 plates. (London: William Collins, Sons and Co., Ltd., 1955.) 30*s*. net.

IT is a sobering thought that, of the 280 species of bird which spend a substantial part of their lives in the British Isles, we still only have adequate and up-to-date monographs of a bare dozen. David Lack's "Life of the Robin" (1943) set a new standard, which has been well maintained by the seven books devoted to individual bird species that have appeared in the New Naturalist Series. The latest of these, by the leading British amateur worker in bird behaviour, is on the second smallest British bird, the wren (*Troglodytes troglodytes*). Though the book is formally devoted to the familiar European species, in fact, such is the wealth of comparative material presented that it almost becomes a treatise on the wrens of the world. This is an immensely valuable feature of the book, for students of British birds are more than usually prone to the myopic views engendered by insularity. Again and again, obscurities in the habits and biology of a British species can only be resolved by reference to the populations of the same bird in other parts of its range, or to quite different members of the same genus or family.

Ornithologists will all regret the author's statement in his preface that "the requirements of this series have necessitated drastic abbreviation and condensation", for it is always less convenient to have to turn to other sources for a complete conspectus. Thus, for extended information on parasites and nidicoles of the wren, one must now turn to the author's paper in Vol. 11 of the *Irish Naturalists' Journal*. However, authors must bow to economics, and ornithological readers must be thankful for being allowed to have as much between two covers as they are offered in this book. The work contains, in fact, a very adequate treatment of every important aspect of the life-history of the wren, largely based on the author's own field studies in a small wood near Cambridge. It is always dangerous to base a general study of a species on the particular circumstances in one locality, but in this book the author's wide reading, together with extensive field studies of wrens in other parts of the British Isles, and in Iceland, have obviated as far as possible any bias due to the quirks of Cambridge wrens.

If it were necessary to standardize monographs on birds (which Heaven forbid!), this would make a very satisfactory book on which to base the standard. There are twenty excellent photographs in black-and-white, by the author and others. R. S. R. FITTER

MALAYAN FERNS

178

Ferns of Malaya

By Prof. R. E. Holttum. (A Revised Flora of Malaya: an Illustrated Systematic Account of the Malayan Flora, including Commonly Cultivated Plants—Vol. 2.) Pp. iv + 643 + 3 plates. (Singapore: Government Printing Office, 1954 [1955].) 20 Malayan dollars.

PROF. R. E. HOLTTUM'S book on Malayan ferns, the second volume of his revised "Flora of Malaya", maintains—even surpasses—the high standard set up by him in the first volume, devoted to the orchids. Van Alderverelt van Rosenburgh's account has long outgrown its usefulness, and an up-to-date and authoritative successor to it was much desired. Not only has the author described about five hundred species of ferns, but he has also provided 362 excellent line-drawings. The descriptive part of the volume is prefaced by chapters dealing with the nature, classification and nomenclature of ferns, followed by an interesting study of Malayan ferns in particular. Keys to identification are also provided.

Prof. Holttum naturally follows his own system of classification, which differs markedly in some respects from that of Copeland. This is no place to compare the two schemes; but mention must be made of the family Dennstaedtiaceae. The name was first proposed by Ching in 1940 for a small homogeneous group of genera centred around *Dennstaedtia*. When Prof. Holttum adopted the same name for a very much larger group of genera, he was doubtless unaware of Ching's work. Holttum's family comprises about seventy genera, as opposed to eight in Ching's scheme, and is so heterogeneous that the author has found it impossible to supply a family description. Subdivided into eleven subfamilies, it embraces such diverse elements as *Davallia*, *Acrostichum*, *Dryopteris* and *Pteris*, to mention but a few. Treated as families, these subfamilies would have invited little criticism since they are compact natural groups. Their amalgamation as a family will be regarded by some as far from natural. The treatment of the Hymenophyllaceae and Gleicheniaceae is frankly conservative, and the smaller segregate genera accepted by Copeland are not adopted. In the case of the Hymenophyllaceae, however, the corresponding segregate name of every species is given as an "alternative name".

A particularly interesting and novel feature of the book is an appendix, prepared by Prof. I. Manton, on the cytology of a hundred species of Malayan ferns. It is to be hoped that Prof. Manton's plea for further investigation of other species along the same lines by workers in Malaya will meet with a favourable response.

Prof. Holttum's book is well printed and commendably free from typographical errors. It should be pointed out, however, that *Ophioglossum pedunculosum* Desv. is now known as *O. reticulatum* L.

O. pedunculosum is a synonym of *O. costatum* R. Br. and is an entirely different species. Also, the varietal epithet '*alternans*' has been inadvertently omitted from the caption on the frontispiece.

It is to the observations accompanying the descriptions that the book largely owes its readability, and there is much to be learned by the specialist as well as by the less-informed reader. Apart from its value to the field-worker in Malaya, the book is essential for all those who have a genuine interest in ferns as a whole.

F. BALLARD.

CHEMISTRY AND PHYSICS OF RADIOACTIVE MATERIALS

Nuclear and Radiochemistry

By Gerhart Friedlander and Joseph W. Kennedy. (Revised version of "Introduction to Radiochemistry".) Pp. ix+468. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 60*s*. net.

IN the preface to their earlier work, "Introduction to Radiochemistry", the authors went to some trouble to define the subject. They have had second thoughts since then, and in the preface to this new volume they propose that the field which they previously defined as nuclear chemistry should no longer be regarded as a part of radiochemistry. Radiochemistry is now to be thought of as including chemical manipulations of radioactive sources and much of tracer chemistry. For these reasons, the title has been altered to "Nuclear and Radiochemistry". The old title may have been unsatisfactory and certainly did not please everybody; but, in the reviewer's opinion, the use of the term nuclear chemistry for describing certain parts of nuclear physics is not a happy one.

Whatever the meaning of the title, the book deals very largely with those parts of nuclear physics which are of interest to chemists. The authors have attempted to cover a wide field by selecting elegant and economical methods of presentation. They have, on the whole, succeeded admirably; only in a few instances has economy been carried too far. In Chapter 2, for example, the section on isotope separations has been reduced to a bare statement of techniques available.

The book is intended primarily for graduate or senior undergraduate students, and emphasis is very properly laid on ideas and principles. The research worker cannot, therefore, expect to find the degree of detail in chapters such as that on radiation detection and measurement, which he requires for his day-to-day work. On the other hand, few research workers in the field of radiochemistry will care to do without a book which contains such a wealth of carefully selected information on the physical background to the subject.

The authors have devoted rather a small fraction of their space to chemical aspects, and the treatment is often quite elementary. Radiation chemistry, which was excluded from "Introduction to Radiochemistry" as not strictly belonging to the subject, has been accorded a brief section in the new volume. This is probably desirable in order to round off a valuable chapter on interaction of radiations with matter. There is a statement, however, to the effect that "most organic systems are much too complex to encourage any detailed studies of the mechanism of their radiation decomposition", which is surely too pessimistic. The problem may be more difficult than that of organic pyrolysis, but modern analytical developments give grounds for better hopes. New chapters, on nuclear energy and on some cosmic problems, have been added in the new volume, and they make a useful addition. It is curious to note, however, that the section on chemical processing seems to be out of line with recent publication in this field. A coprecipitation process is chosen by way of example, and doubt is cast on the suitability of solvent extraction methods because of radiation effects; actually it has been common knowledge for some years that solvent extraction methods are in fact used.

Each chapter is followed by about a dozen well-chosen exercises, and there are about forty pages of appendixes devoted to a most useful compilation of nuclear data. This is an outstanding book, well conceived and well written. It can be strongly recommended to all radio (and nuclear ?) chemists.

THE FIRST HUNDRED YEARS OF THE CURTIS MUSEUM, ALTON

The Curtis Museum, Alton, Hampshire, 1855–1955

The First Hundred Years of a Small Museum. By William Hugh Curtis. Pp. vii+55+10 plates. (Alton: Curtis Museum, 1955.) 6*s*.

IT is now fully realized that much of the visible evidence of the heritage of Great Britain lies in the numerous small museums scattered unequally throughout the land. The consciences of the trusts, societies and public authorities owning these institutions have been awakened to their responsibility, and a very great amount of energy and enthusiasm is being expended into transforming these one-time hoards of junk into displays worthy of the best of modern trends in the museum world. A great deal of the credit for this must be given to the Carnegie United Kingdom Trust, which, with the Museums Association, has done much to stimulate and inspire the local museum.

The history of the Curtis Museum in Alton, Hampshire, during the past one hundred years is interesting and instructive not only for its own sake but also as an indication of the trend of development in so many of the museums of Britain. It is written in a clear, straightforward manner by Mr. W. H. Curtis (a grandson of the founder, Dr. William Curtis), who is probably the only one living who could write such a record of what has been so essentially a family concern.

It was in 1837 that William Curtis founded the Alton Mechanics Institute, which, like so many others, led to the establishment of a Museum in 1855. It started with about four thousand specimens, many of which were fossils and minerals, though in common with museums of that period included a quantity of foreign material of all sorts. In 1920 the Museum was transferred to the Alton Urban District Council, and Mr. W. H. Curtis was appointed honorary curator. It is interesting to note that in 1929 the acquisition of bygones was a definite feature in the policy of the Museum—the swing of interest from natural history had begun. At first efforts were concentrated on agricultural, domestic and personal objects, but eventually the search for the tools of rural craftsmen was actively pursued.

An important event in 1934 was the inaugural meeting of "The Friends of the Curtis Museum", a body which has done much for the Museum and continues to the present day. In 1946, the Museum was transferred to the Hampshire County Council under the terms of the Education Act, 1944. A grant from the Carnegie Trust was announced in 1949, and this helped the Museum to assume the modern aspect which characterizes it at the present day. In 1951 the appointment of a full-time curator brought the Museum into line with so many similar institutions up and down the country. The history concludes with an appreciation by Mr. C. P. Chatwin on the geological work of William Curtis.

This stimulating, almost year-by-year, record of the vicissitudes of a local museum is of interest not only to the community in Alton but also to the wider museum public, who see in it an epitome of what has happened at so many centres.

PATHOLOGY OF CANCER

The Genesis and Prevention of Cancer

Second Edition. By W. Sampson Handley. (London: John Murray (Publishers), Ltd., 1955.) 21s.

THE first edition of Mr. W. Sampson Handley's book appeared a quarter of a century ago. Although this new edition has recently been revised, the author's original ideas as to the cause of cancer remain unchanged. Many theories of the causation of malignancy are discussed and discarded. The virus theory is dismissed, and the author predicts "no specific organism of cancer will ever be discovered". Mr. Sampson Handley contends there is a definite correlation between the induction of cancer and lymph-statis. This theory was gradually built up over twenty-five years of clinical and histological study of the disease in all its many manifestations. He marshals evidence for his conclusion that precancerous lesions are areas in which the lymphatic vessels have either been blocked or else obliterated by chronic inflammation or congenital defect. He further argues that, as lymphatic obstruction always precedes cancer, it is therefore the main factor in causing the disease.

This view, although not universally accepted by pathologists as the cause of cancer, might hold for some types of malignancy. It would be an over-simplification to accept this theory as the universal cause of cancer. For example, it would be difficult to explain the origin of some forms of endocrine cancers, which depend on hormones both for their induction and maintenance, and which regress once the hormonal stimulus is withdrawn. Under such conditions, do accompanying changes first occur in the lymphatics before the onset of the disease, and can they be expected to disappear during regression? If so, they have not been adequately demonstrated.

Mr. Sampson Handley has done admirable pioneer work on the pathology of breast tumours, and has contributed greatly to our present knowledge of the spread of tumours via the lymphatic pathway. Although many might find his theories controversial, they will also find them stimulating. All who are interested in the histology of the early development of tumours should read this book.

There is also a chapter on cancer prophylaxis. Among the many preventive measures discussed, preputiotomy in children is recommended at birth in order to reduce the incidence of cancer both of the penis and the cervix. In this same chapter, when discussing constitutional factors such as hormones in the etiology of the disease, he contends that they "play only a subordinate part". This attitude is scarcely in accord with modern biological findings.

The book is well illustrated and has an appendix entitled "Tobacco and Cancer", in which some interesting statistics are given concerning lung cancer and other diseases occurring among heavy smokers.

CHROMOSOMES OF HIGHER PLANTS

Chromosome Botany

By Prof. C. D. Darlington. Pp. xii+186. (London: George Allen and Unwin, Ltd., 1956.) 16s. net.

IN this useful little book are summarized the important facts and points of view concerning the chromosome numbers and chromosome morphology of the higher plants (chiefly the Angiosperms), and the significance of their cytology in clarifying the taxonomy, phylogeny, geographical distribution and ultimately the evolution of the plants concerned. The facts and points of view are mainly those which have emerged during the period 1930–56; approximately the period since the publication of the first edition of the "Recent Advances in Cytology". Most of the topics dealt with in this epoch-making book have now received a revised treatment from the author in the several volumes written independently or in collaboration with Prof. K. Mather. The present volume brings to a considerable degree of completeness an achievement represented by books which are essentially challenging presentations of facts rather than dispassionate compilations. The reviewer does not forget that compilations and a practical handbook have been provided as well.

B-chromosomes, apomixis, microspecies, polyploidy and plant geography, ecological variation, change of basic chromosome number, change of chromosome morphology and chromosome size, centres of diversity, wheat, maize, *Rosa*, *Chrysanthemum*, are among the subjects treated, often with useful detail. On certain of them it has long been desirable to be able to quote the author's views. On the whole, these views do not differ markedly from those generally held, although, as always, it would be easy to quote sentences from this author with which few would agree. There are no complex diagrams. The sections dealing with basic numbers are particularly illuminating, although the bold assertion of 1949 in regard to the basic chromosome number of the ancestral Angiosperms is repeated here and their seven chromosomes appear on the dust-cover. Broadly, the book is an elaboration of the introduction to the first edition of the "Chromosome Atlas".

There is a separate bibliography for each chapter; but authors' names are also indexed. One feels that the names of some whose ideas have been assimilated, perhaps subconsciously, should not have been missing, for example, those of Huxley and Turrill; yet, of course, it is an advantage that the size of the volume has been kept down to that which a student can afford to buy. Every serious student of botany should be recommended to purchase this book, the only one of its kind published in Britain. There is an informative little appendix by E. B. Ford, on moths, butterflies and *Primula*.

M. B. E. GODWARD

AMEDEO AVOGADRO (1776–1856)

By PROF. J. R. PARTINGTON, M.B.E.

PROBABLY no name is better known to students, even the most elementary, of chemistry and physics than that of Avogadro; but this was not always so. He is not mentioned in the detailed histories of chemistry of Hoefer and Kopp, and in the biographical dictionary of Poggendorff he first appears in the third volume in 1898. The details of his life are to be found only in the very rare "Opere Scelte di Amedeo Avogadro", printed for private distribution by the Turin Academy of Sciences in 1911, the centenary of the publication (in French) of his famous hypothesis in the widely read *Journal de Physique*. The "Opere" has a long introduction by Prof. Icilio Guareschi and contains the first Italian translation of Avogadro's memoir of 1811. It also prints a letter from Faraday in 1842, thanking Avogadro for his last letter and saying (the letter is in Italian) that he had read the first two volumes of his great work with much profit, "sebbene io legga l'italiano con stento". This would be the "Fisica de' corpi ponderabili" (4 vols.; Turin, 1837–41), and Faraday says he had ordered the third volume from Paris.

A member of a distinguished Italian family, Amedeo Avogadro (to use his own contraction of his very long complete name) was born in Turin on August 9, 1776, and died a hundred years ago on July 9, 1856. He became bachelor of law in 1792, later doctor of eccelesiastical law (a family vocation), and practised for a time. He became interested in mathematics and physics, and in 1809 was appointed professor of philosophy in the Royal College of Vercelli. In 1820 he filled the first Italian chair of mathematical physics in Turin, which was suppressed for political reasons in 1822. The chair was restored in 1832 but was occupied for a year by Cauchy, the distinguished French mathematician, when it was re-occupied by Avogadro from 1834 until his retirement in 1850. The "Opere" lists more than fifty publications by Avogadro—all except the memoir of 1811 known only to specialists. He took an active part in public affairs and was a very cultured man with many friends among distinguished scientists in all countries; but he received no honours, partly because of his modesty and partly because he was so fully occupied with scientific work that he had no time to seek them.

Avogadro's famous memoir of 1811 is entitled "Essai d'une manière de déterminer les masses relatives des molécules élémentaires des corps, et les proportions selon lesquelles elles entrent dans ces combinaisons". He uses the names "molécule" and "molécule intégrante" for molecules in general, "molécule constituante" for a molecule of an elementary substance, and "molécule élémentaire" for the atom of an element. The title, therefore, shows that he is concerned, in fact, with atomic weights. The nomenclature and the clumsy and sometimes obscure French in which the paper is written make it difficult to understand. It announces the hypothesis that "le nombre des molécules dans les gaz quelconques est toujours le même à volume égal . . . les rapports des masses des molécules sont alors les mêmes que ceux des densités des différents gaz, à pression et température égales". A long supplement, which is little known, appeared in the *Journal de Physique* in 1814.

Avogadro makes it clear that the origin of his memoir was the publication in 1809 by Gay-Lussac of his law of volumes, in the form that gases "se combinent entre elles dans des rapports très-simples, et la contraction de volume qu'elles éprouvent par la combinaison suit aussi une loi régulière". This shows, said Avogadro, that "il y a aussi des rapports très-simples entre les volumes des substances gazeuses, et le nombre des molécules simples ou composées qui les forme". Gay-Lussac read his memoir to the Société d'Arcueil on December 31, 1808; it is purely experimental. In 1808 Dalton, in the first volume of his "New System of Chemical Philosophy", had said that "it is evident the number of ultimate particles or molecules in a given volume of one gas is not the same as in another", since one volume of nitrogen and one of oxygen form two volumes of nitric oxide, in which "the number of ultimate particles could at most be one half of that before the union".

This difficulty Avogadro resolved by the assumption that the molecules (a name which, it will be noticed, was used by Dalton) of elementary gases may contain two or more atoms and that the particles resulting from their union may divide. In modern symbols: $N_2 + O_2 = N_2O_2$; $N_2O_2 = 2NO$. In comparing the weights of molecules from the ratios of densities, Avogadro took the molecular weight of hydrogen as unity, so that his molecular weights are half the modern ones.

In 1814 Ampère published the same conclusions as Avogadro, mentioning him only in a footnote, so that Avogadro said in 1849: "Ampère a depuis adopté ce principe". Ampère suggested that the molecules of elementary gases contain four, not two, atoms, and made further obscure speculations about the geometrical forms of the particles. Dumas in 1826 is the only chemist to name Avogadro before 1850; others, when they refer to the hypothesis at all, credit it to Ampère, as did Gaudin, who in 1833 gave a detailed and clear exposition of it, which was favourably noticed by Berzelius.

Avogadro died on July 9, 1856, and his hypothesis was then in a state of full neglect. There were reasons for this. All attempts to construct a uniformly acceptable set of atomic weights had failed, and chemists had fallen back on the use of equivalent weights determined directly by experiment. Dumas in 1826 had found very abnormal vapour densities of sulphur and phosphorus, which had no clear relation to the accepted atomic weights; and, finally, the vapour densities of ammonium chloride, phosphorus pentachloride and sulphuric acid were only half those expected.

In 1858, Cannizzaro, then professor in Genoa, distributed a small pamphlet based on his lectures, in which he cleared up the difficulties of abnormal vapour densities by assuming that the sulphur and phosphorus molecules contain more than two atoms, and that ammonium chloride, etc., dissociate on heating and, thus occupying a larger volume, have abnormally low molecular weights. Cannizzaro showed that Avogadro's hypothesis, which was now restored to its rightful originator, could be applied without exception. He referred both atomic and molecular weights to the *atom* of hydrogen, instead of (as Avogadro did) to the molecule; the ratio of the molecular weight of any gas or vapour to that of hydrogen is the ratio of the densities, and since the hydrogen molecule is H_2, the molecular weight of the other substance, in terms of the atomic weight of hydrogen, is twice the relative density. The atomic weight of an element is then the smallest weight of it contained in a molecular weight of any of its compounds. These two features are important contributions by Cannizzaro.

Lothar Meyer was much impressed by Cannizzaro's pamphlet, and in his "Moderne Theorien der Chemie", published in 1864, he gave a clear account of the bearing of Avogadro's hypothesis on molecular and atomic weights. A similar service was rendered by Hofmann in his "Introduction to Modern Chemistry" in 1865. From that time the significance of the hypothesis came to be clearly perceived, and it now ranks next to Dalton's atomic theory in the structure of theoretical chemistry.

The kinetic theory of gases, developed by Clausius (1857) and Maxwell (1860), showed that Avogadro's hypothesis (they do not mention his name) follows from the assumption that the average kinetic energy of translation of gas molecules is proportional to the absolute temperature, and the significance of the hypothesis was thus seen by physicists. Avogadro was, in fact, a mathematical physicist, not a chemist in the proper sense. The hypothesis was seen to penetrate such diverse branches of physics as the kinetic theory, the Brownian movement, radiant heat, the scattering of light, the electronic charge, and the counting of α-particles. It became possible to determine the number of molecules in a molecular weight in grams of any substance, a constant of Nature now called Avogadro's number and equal to $6 \cdot 02 \times 10^{23}$. If it can be said with truth that the real existence of atoms and molecules has been experimentally demonstrated, it can be asserted with equal confidence that Avogadro's statement is no longer what he himself called it, a 'hypothesis'. A generation ago, students were warned by meticulous teachers not to call it Avogadro's 'law'; but this name would now seem to us much less objectionable.

Avogadro did not live to see the full recognition of his great service to chemistry and physics. Now, however, in commemorating the centenary of his death, no obscure name is rescued from oblivion but homage is paid to one long acknowledged as a master.

FINE STRUCTURE OF SOME CILIATE PROTOZOA

By Prof. J. T. RANDALL, F.R.S.

Wheatstone Physics Laboratory and Medical Research Council Biophysics Research Unit,
University of London, King's College, W.C.2

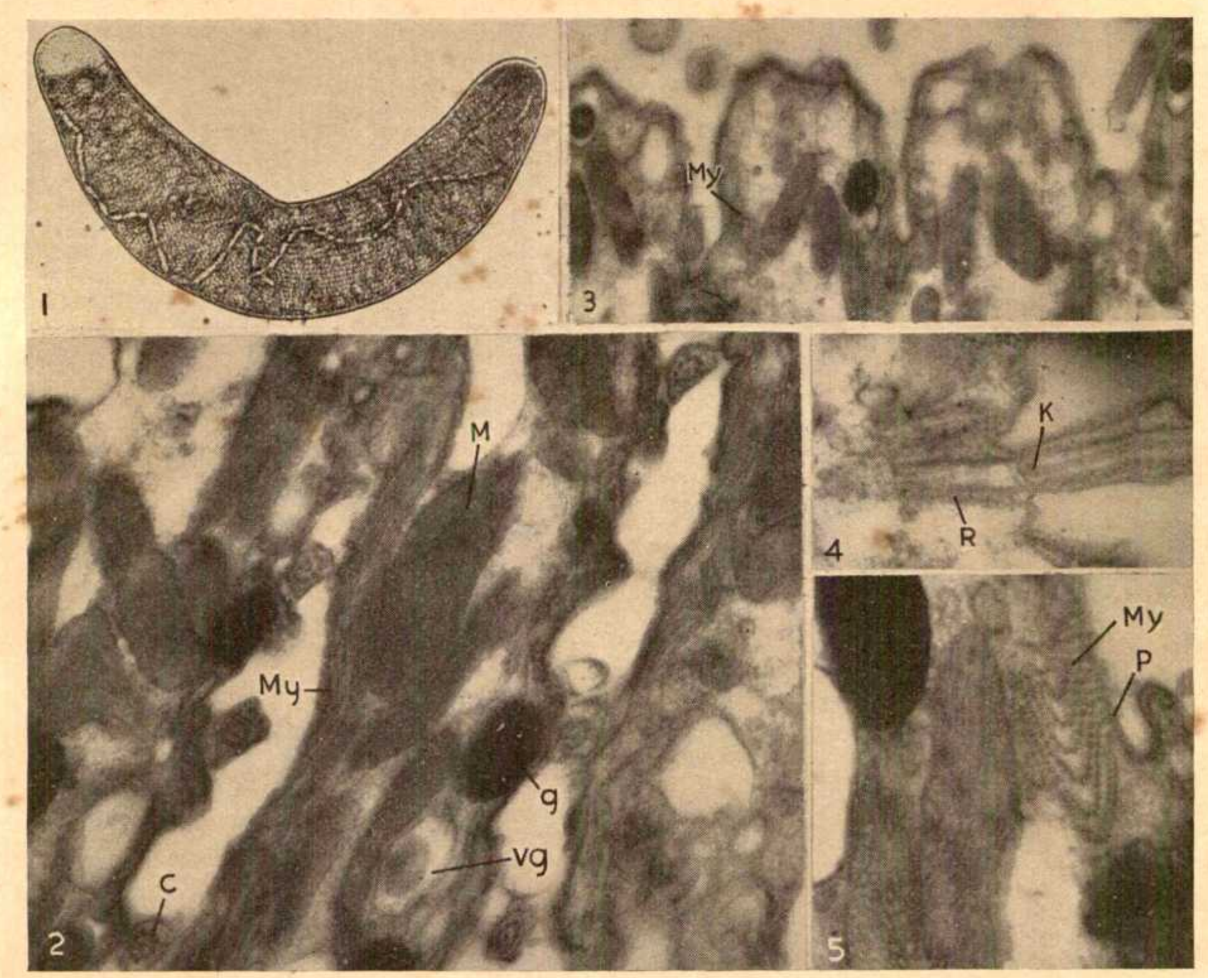
IN this article I wish to outline some of the more important features of the fine structure of certain ciliates which have been observed in the electron microscope. Most of the currently accepted information about Protozoa has been obtained with the help of the light microscope[1,2], and has clearly been restricted by the limited resolving power of this instrument. It is surprising that, in the ten or fifteen years during which the electron microscope has become an increasingly important and popular tool in the study of biological fine-structure, the study of Protozoa has been a comparatively neglected field. The start given to such investigations by Jakus and her collaborators[3-5] does not seem to have been followed, until very recently, to the extent that might have been expected. This is probably accounted for by the fact that Protozoa are in general rather large and thick organisms for study in the electron microscope without the aid of the thin-sectioning microtomes which have themselves only been developed in the past few years.

In the field of biological fine-structure, Protozoa offer many attractive possibilities. Among them may be mentioned: (1) structure of the nucleus, the nucleolus and the nuclear membrane; (2) protozoan cytoplasm with its many inclusions; (3) fine-structure of the protozoan pellicle and ectoplasm; Sedar and Porter[6,7] have recently made such investigations for *Paramecium multimicronucleatum* and Powers *et al.*[8,9] have studied mitochondrial structures in *Paramecium* species; (4) ciliary apparatus of the ciliates, including membranelles; (5) contractile structures or myonemata of the ciliates, to which I give special attention below; (6) sexual and asexual reproduction and the phenomena of mitosis in the Protozoa, which also suggest many interesting comparative studies with higher organisms. These are but a few of the approaches that may be made in this interesting field.

In this article I shall be concerned with three members of the Ciliophora: *Spirostomum ambiguum*, *Carchesium* sp. (probably *polypinum*) and *Stentor polymorphus*. The material has been fixed in a combination of osmium tetroxide and Zenker fluids and then embedded in a methacrylate medium. After appropriate polymerization of the plastic, thin-sectioning of the organisms was carried out on a microtome designed in this Laboratory. It has not been possible to illustrate all structural features to which reference has been made in the text, but fuller accounts will be made available as soon as possible; a more detailed description of the work on *Spirostomum* is already in course of publication[10].

Spirostomum ambiguum (Ehrenberg)

This heterotrich has a uniform body ciliation with a funnel-shaped pharynx and a long peristome roughly parallel to the body-axis. The surface of the body (see Fig. 1 for photomicrograph of the living animal) is crossed by perhaps as many as forty kinety along which the cilia are uniformly distributed. The kinety are separated by ectoplasmic ridges. Longitudinal sections through the ectoplasm which cut transversely through a number of cilia may be seen in Fig. 2. Fig. 3 is an electron micrograph of a transverse section through the ectoplasm, and the characteristic ridges and furrows may be seen



Spirostomum ambiguum

(1) Photomicrograph of a living animal showing the longitudinally arranged kinety, the beaded macronucleus, the contractile vacuole and the dorsal canal. × 120

(2) Electron micrograph of an oblique section through the ectoplasm which shows the ridges, transverse sections of cilia (*c*) lying in the furrows, mitochondria (*M*), two types of granular inclusion with — (*vg*) — and without — (*g*) — a vesicular membrane, and longitudinal sections of myonemes (*My*). × 32,000

(3) Transverse section through the ectoplasm showing the ridges and furrows (kinety) at the surface of *Spirostomum*. Myonemes (*My*) are localized asymmetrically at the left side of each ridge. × 16,000

(4) Longitudinal section of a cilium showing its kinetosome (*K*) and dependent root-like fibrils (*R*). × 35,000

(5) Transverse section through the fibrillar myoneme sheets (*My*) which are attached to the inner plasma membrane (*P*) at one end. Note the two types of mitochondrial structure. × 45,000

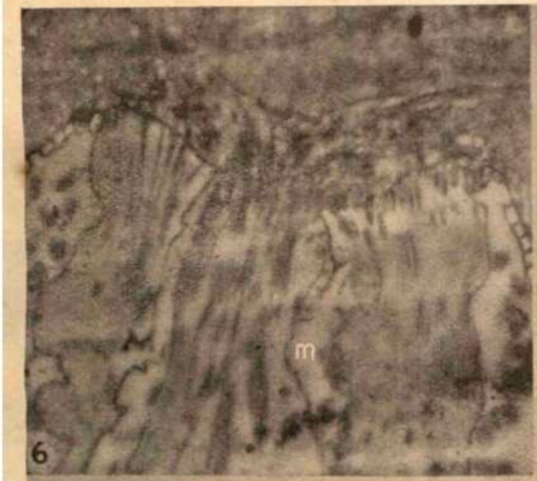
n this picture. The periplast of *Spirostomum ambiguum* has an overall thickness of about 500 A. and appears to be double. The inner component is referred to below as the plasma membrane.

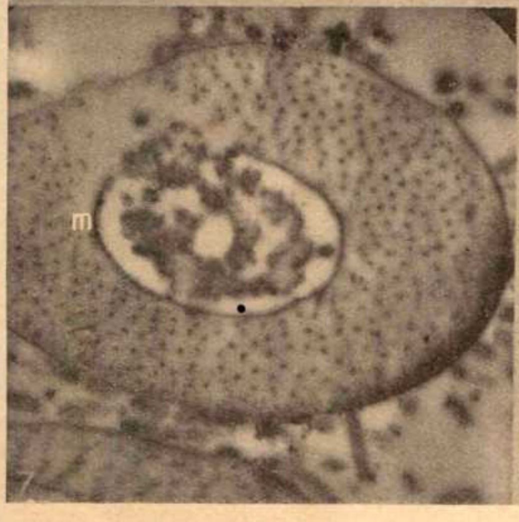
The external membrane of each cilium is continuous with the outer layer of the periplast. This membrane encloses a system of filaments, two of them approximately axial, and nine peripheral; each of the nine outer filaments is, in the best micrographs, resolved into two closely adjacent filaments. Each cilium is about 1500 A. in overall diameter. A longitudinal section through the basal apparatus (Fig. 4) clearly shows a granule, *K*, presumably the core of the kinetosome, which appears to be surrounded by twin septa. From the outer and lower part of the septum two rootlets, *R*, extend into the ectoplasm.

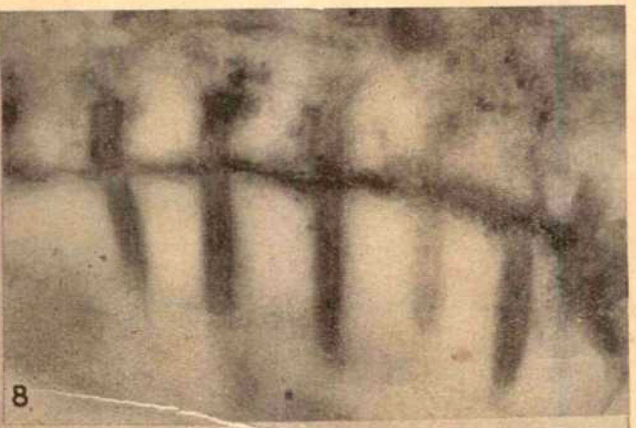
Earlier investigators with the light microscope have naturally given much attention to the problem of the detailed structure of the pharyngeal membranelles (for example, Bishop[11]). On the basis of the evidence I have obtained so far, the view that the motile portion of each membranelle in *Spirostomum* is composed of laterally joined cilia does not seem to be justified. I would, however, prefer to defer conclusions on this complex matter until I have made further observations.

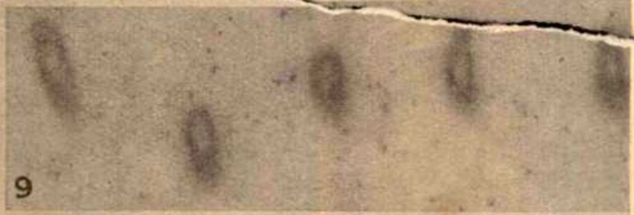
Long, slightly ovoid, bodies with fine structure characteristic of mitochondria have been observed in large numbers in the ectoplasm of *Spirostomum* (Fig. 2). Detailed examination of these bodies has led me to conclude that they may be separated into two distinct groups. In the first group (Fig. 5) the mitochondria are composed of sheets about 150 A. thick which are separated from each other by a layer of less dense—or possibly less osmiophilic—material of rather greater thickness. The total surface area of the sheets inside a mitochondrion represented by a cylinder 1 micron long and $\frac{1}{3}$ micron in diameter would be 1·25 cm.^{2}; each mitochondrion appears to be enclosed in a single membrane. Instead of this simple stratified structure, it is more usual, however, to find a modification in which the internal organization appears to consist partly of sheets (as above) and partly of small tubular vesicles which are typically elliptical in cross-section (see also Figs. 2 and 5). The lumen of the vesicles is often about 430 A. × 250 A. and the wall-thickness about 200 A. In the paper already referred to[10], it has been shown how such a vesicular structure may have been derived from a system of undulating sheets. The mitochondria that fall into the second group have so far been found only in small numbers in *Spirostomum*, but may be recognized as the type usually observed in metazoan tissues (see also Fig. 14 for *Carchesium*); such mitochondria contain a number of characteristic vesicular structures somewhat irregularly arranged. Without much more detailed investigation it is impossible to say whether the two groups into which I have divided the mitochondrial bodies of *Spirostomum* are really distinct, or whether the second group arises as a somewhat swollen or distended version of the first.

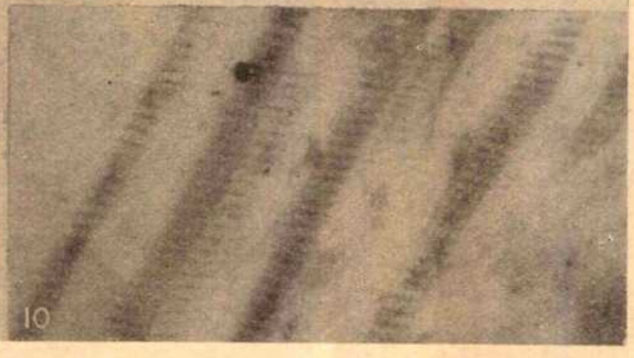
The most elementary observations of living *Spirostomum* show that the animal must possess some means of extremely rapid contraction. The history of the study of the myonemes of *Spirostomum* has been described in some detail[11]; such structures have in the past been inferred from examination by light microscopes of living and of fixed-and-stained material. The electron microscope observations show that the effective width of a myoneme is close to the limit of optical resolution. This accounts for the often conflicting observations which have been recorded. Fig. 3 is a transverse section of *Spirostomum* showing the pellicle and ectoplasm of two ridges and their neighbouring furrows. Attention is particularly directed to the structures, *My*, apparent on the left-hand side of each ridge. These structures are provisionally identified with the myonemes. Each myoneme appears to consist of a number of fibrillar ribbons or sheets, often about ten, which presumably extend the full length of the animal. Fig. 5 shows in greater detail a transverse section of a single myoneme. One side of each ribbon is attached longitudinally to the plasma mem-











Carchesium

(6) Longitudinal section of the junction of stalk and zooid which shows that the cytoplasm is continuous with the central canal; the junction is marked with a root-system, which may have a ciliary origin, and which may be attached to the longitudinal filaments of the annulus. × 3,000

(7) Transverse section of the stalk showing the central canal and the annulus which contains numerous filaments seen in cross-section. × 3,000

(9) An oblique section of the annulus which shows the tubular form of the filaments. × 32,000

(10) Longitudinal section of the striated filaments from the annulus of the stalk. Periodicity, 3[illegible]0–700 A.; diameter about 1400 A. × 35,000

brane, *P*, on one side of each ridge. There is apparently no permanent attachment of the distal ends of ribbons, each of which is simply embedded in the ectoplasm. The extended width of a ribbon is about 5000 A. The fibrils, which are the main feature of the ribbons, consist of an outer dense layer and an inner less dense core; the overall diameter of the fibrils is about 250 A. (Fig. 5). In longitudinal section the myoneme ribbons appear as narrow lines parallel to the plasma membrane (Fig. 2). The dimensions of the myonemes given above refer to contracted material.

The ectoplasm of *Spirostomum* contains in addition to the mitochondria two distinct forms of granular structure (*g* and *vg*) often about 0·5μ in diameter. The simpler structure (*g*) is composite and contains many small particles with no evidence of an enclosing membrane. The more complex structure (*vg*) consists of an apparently dense multigranular core which is enveloped in a well-formed membrane clearly separated from the inner structure. Both types of granule may be seen in Fig. 2. No such granular structures have so far been observed either in *Carchesium* or in *Stentor*.

In the electron micrographs of *Spirostomum* there is a fairly sharp transition from ectoplasm to endoplasm; no evidence of an intermediary membrane, however, has been found. The endoplasm is heavily vacuolated, and the ectoplasm is connected to the endoplasm through a widely spaced series of canaliculi which separate neighbouring vacuoles from each other. Although the vacuoles are often associated with a number of small vesicles, the features so far recognized by others as characteristic of contractile vacuoles have not been clearly observed. Food vacuoles have been found in many of the sections examined.

Carchesium

This peritrich may readily be distinguished from *Zoothamnium* on one hand and *Opercularia* and *Epistylis* on the other. In *Carchesium* each branch of the stalk is independently contractile; in *Zoothamnium* the whole colony contracts as one. *Opercularia* and *Epistylis* are non-contractile. I am not certain of the species of *Carchesium* examined; but it is probably *polypinum* (see Fig. 11 for a photograph of the animal under the light microscope). Fig. 12 gives a low magnification view of a transverse section through parts of the ciliary system near the mouth of the zooid; notable in the lower part of the micrograph is the triple row of cilia. In another section cut closer to the root system (Fig. 13) each cilium is joined laterally to its neighbours in the same row by short filaments about 1500 A. long and 200 A. wide. The endoplasm in both the above micrographs is filled with mitochondria which are of the vesicular type common to metazoan tissues and are similar to the Type II mitochondria of *Spirostomum*; Fig. 14 shows part of a *Carchesium* mitochondrion at higher magnification. Regions of the endoplasm near the cytostome in *Carchesium* have been found to be in a highly organized state (Fig. 15) reminiscent of the structures found in the mitochondria (Type I) of *Spirostomum*; the significance and extent of this elaborate system of sheets and vesicles, however, are not yet known.

The stalk consists of two distinct parts: an annulus, which is threaded by numerous longitudinal tubular filaments, marked with a periodic striation, and a central core or canal which appears to be continuous with the endoplasm of the zooid and is separated from the annulus by a single membrane, *m* (Figs. 6 and 7). The stalk, after fixing and embedding, generally appears elliptical in section, and the core is about half as wide as the annulus is thick (about 10^{-3} cm.) (Fig. 7). Bodies similar to mitochondria have frequently been observed in the core of the stalk and well removed from the stalk–zooid junction. A primitive type of root system occurs at the junction of the stalk and zooid (Figs. 6 and 8); but precise evidence of the nature of this connexion is so far lacking. The system does not appear to be related in any way to the basal ciliary wreath of a dividing zooid, although it seems extremely likely that it may have a modified ciliary origin. The striated longitudinal filaments of the stalk may be attached to the root system[12].

The filaments of the annulus are seen in longitudinal section in Fig. 10; the axial periodicity of their striations varies widely but generally lies in the range 300–700 A.; in transverse section the filaments are tubular and usually about 1400 A. in diameter. It is tempting to suggest that these striated longitudinal filaments are the contractile structures or spasmonemes of the stalk of *Carchesium*. On the other hand, Rouiller, Fauré-Fremiet and Gauchery[12] have very recently shown that the non-contractile stalk of the *Opercularia articulata* is also threaded with similar striated filaments.

The contractile mechanism of the stalks of such peritrichs as *Carchesium*, *Zoothamnium* and *Vorticella* has generally been associated with the central canal; this feature has not been observed in the non-contractile stalks of *Opercularia* and *Epistylis*. A careful search has therefore been made in *Carchesium* for the existence of possible contractile fibrils in the central canal of the stalk. Suggestive structures have been seen from time to time; but they have not been convincing and give the impression rather of stress regions in a comparatively uniform gel.

Thus in the present stage of knowledge it is possible only to speculate about the nature of the contractile mechanism. The striated filaments

observed in the stalks of the genera so far examined may all be potentially contractile. The function of the canal and its membrane in contractile species may be analogous to the function of the sarcoplasm and the sarcolemma in muscle fibres. Alternatively, the filaments may not themselves be contractile but may merely perform a strengthening or supporting function. Contractility may be achieved through an as yet unverified system of fibrils within the central canal, through the contractility of the canal membrane, or through the contraction of the amorphous gel surrounding the outer filaments. It is hoped that further comparative studies may help to solve this intriguing problem.

The outer boundary of the zooid of *Carchesium* is quite different from the periplast of *Stentor* or *Spirostomum* and may be seen in transverse section at *F* in Fig. 12. This boundary has a fluted appearance which may be caused by a longitudinally arranged series of tubular structures. The overall width of this system in the fixed material is about 5000 A.

Stentor polymorphus (*Müller*)

Stentor polymorphus (Fig. 17) is a heterotrich which is trumpet-shaped and, like *Spirostomum*, highly contractile. Only a limited number of the characteristic structures revealed by electron microscopy can be discussed here. In longitudinal sections of the body the most interesting structures are those probably associated with contractility; they are referred to below as myonemes, although it will be again obvious that electron micrographs do not in themselves provide evidence of contractility. Transverse views of the myonemes to be seen in Fig. 19 show them to be not unlike those shown in Fig. 5 for *Spirostomum*; the myonemes of *Stentor* are also situated asymmetrically in each ridge. Present evidence from many micrographs indicates that the myonemes are of indefinite length and in the form of closely associated narrow sheets or ribbons. The coarsely fibrillar structure of *Spirostomum* is not evident in *Stentor polymorphus*. In longitudinal section the sheets appear as a series of closely spaced parallel lines (Fig. 18). Comparison of micrographs suggests that each myoneme comprises about twenty to thirty such sheets (Fig. 18). The thickness of each sheet is about 130 A. and the width about 5000 A. A striking feature of Fig. 19 is the condensation of these sheets into thicker and denser objects; in this form these (presumably contractile) structures are apparently attached to the oral cilia (Fig. 20). In addition, the myonemes which lie in the ridges of the body appear to be attached to the locomotive cilia. This in turn suggests that the ciliary and contractile mechanisms are co-ordinated with one another, and that the contractile fibrils are identical with the kinetodesmata.

Some further remarks must be made about the adoral cilia. Fig. 21 shows that these are in small groups. From each such group an extremely long (8–12μ) root system depends into the body. This system is apparently highly organized; in longitudinal section it is filamentous; in oblique section a lattice-like arrangement is visible, the whole suggesting a regularly arranged system of interweaving sheets. Several very long bodies without clear structural characteristics have also been observed in sections of the endoplasm. It is not known what these are, although they may, of course, be another type or form of contractile structure. Fauré-Fremiet and Rouiller have very recently[13] reported a number of observations on the fine structure of *Stentor* species.

Even at this early stage, mention must be made of the nuclei observed in the three animals so far investigated. In all three the nuclei present a rather grossly granular appearance, and the large granular bodies are composite and react positively to the Feulgen stain. The whole of the space between the granules is filled with very small particles about 100 A. in diameter (Fig. 16). In view of the known difficulties of fixation of Protozoa, the possibility of nuclear artefact cannot by any means be excluded. The recent X-ray diffraction evidence for the long filamentous helical structure of nucleic acid (DNA) in certain intact nuclei makes it all the more necessary to study methods of nuclear fixation with extreme care; and it may be suggested that such methods should be based rather on the expected physical behaviour of polyelectrolytes under defined conditions than on earlier traditions of cytology.

I am indebted to the Botanical School, Cambridge, for the provision of specimens of *Spirostomum* from its collection, and to Dr. J. A. Kitching, of the University of Bristol, for the provision of *Carchesium* and *Stentor*. Dr. Kitching and Dr. Muriel Robertson have been most helpful in initiating me into this field and in the discussion of results. I wish to acknowledge valuable discussion with Prof. E. Fauré-Fremiet, who has simultaneously been investigating similar problems, and with Dr. Jean Hanson of this Laboratory.

It is a pleasure to record the invaluable help of Miss S. Fitton Jackson at all stages of the work.

OBITUARIES

Prof. A. J. Kluyver, For.Mem.R.S.

DURING the night of May 13–14, 1956, Albert Jan Kluyver, professor of microbiology at the Technological University of Delft, Holland, suddenly died at his home of a heart attack, at the age of nearly sixty-eight years. The news of his death will deeply affect all who have known him, because they realize that it signifies the loss of a universally beloved personality and great scientist.

For almost thirty-five years he directed the work at his Institute in a manner that has made the Delft laboratory famous throughout the world as a centre of microbiological research. Under the leadership of M. W. Beijerinck from 1895 until 1921, it had already acquired an enviable reputation; and at the time of his succession to the chair, Kluyver was keenly aware of this and hence also of his great responsibilities, especially in view of the very limited training in microbiology he had received. But he possessed an excellent and highly perceptive mind, and an unrivalled capacity for work. By strenuous and undeviating application he rapidly succeeded in mastering the field, and in a few years he was ready to start developing a programme of his own that has resulted in some of the most far-reaching advances in biochemistry.

His chemical background inclined him from the start to a study of the biochemical activities of micro-organisms. Convinced by an early exhaustive review of the literature on this subject that the existing information did not reach much beyond providing a confusing picture of an almost endless variety of patterns, he began to look for unifying principles. How successful this search has been must be obvious to everyone who is conversant with the fundamental features of present-day biochemistry, which rests squarely on the concepts of the 'unity in biochemistry', and of 'comparative biochemistry' that Kluyver developed in the course of a very short time. These concepts have exerted a fertilizing influence on biochemical progress fully comparable to that which followed the introduction of the comparative anatomical and embryological approach into general biology. The foundation, inception and elaboration of these principles have been brilliantly presented by Kluyver in the series of lectures that he delivered in 1930 before the University of London, published in 1931 by the University of London Press under the title "The Chemical Activities of Micro-Organisms", and in the first two of the John M. Prather Lectures given in 1954 at Harvard University, and recently also published in book form ("The Microbe's Contribution to Biology", Harvard University Press, 1956). It is not too much to say that Kluyver's contributions have been instrumental in establishing the biochemical foundation for Darwin's concept of the monophyletic origin of living beings.

The recognition of the fundamental unity underlying the biochemical activities of extant living organisms should be attributed not only to Kluyver's philosophically inclined mind; equally significant for this development was his profound knowledge of the vast variety of microbes and his perception of their great biochemical potentialities. The possibility of using a particular bacterium, yeast or mould for the investigation of some specific biochemical process has been ably exploited in many studies carried out in his institute. During the first decade of his career as a microbiologist, Kluyver often expressed surprise and regret that this notion was not more prevalent, in spite of his ardent advocacy of its advantages in lectures and publications; he was too enthusiastic to be content with that form of mental inertia that impedes the speedy diffusion of novel ideas. But gradually his admonitions, supported by striking examples of fruitful applications, have had their effect, and developments during the past fifteen years have amply justified the high expectations he had for this type of approach, which has finally been used on a rapidly increasing scale. A consequence of this has been that general microbiology has come into its own as an important branch of biological science, and the reputation of the Delft laboratory has certainly not suffered from Beijerinck's retirement. In fact, the "Delft School" that has so strongly stimulated the rise of general microbiology is a term that properly refers to the period of Kluyver's leadership (see, for example, *Bact. Rev.*, 13, 161; 1949).

It is, however, not merely the scientific output that has made his laboratory one of the most sought-after institutions, to which microbiologists from all over the world have come to learn from the master. It has been the experience of all who have worked there that he contributed far more than his vast factual knowledge and the penetrating insight of a fine scientific mind. For they have also been exposed to a noble personality who had a deep understanding of human behaviour and a profound appreciation of the meaning of individuality. His whole demeanour was an inspiring example of a life radiating encouragement, tolerance and compassion. This attitude compelled much more than respect, and created in his institute a warm and conspicuous atmosphere of enthusiastic, generous and effective co-operation, of love for work, and of personal responsibility.

The same characteristics also made Kluyver a highly valued adviser, and his services were more and more frequently solicited on important national and international committees, where his wisdom usually led to finding genuine conciliatory solutions rather than compromises for difficult problems.

His outstanding significance as a scientist has been widely recognized. Only five years after his appointment to the Delft chair he was elected to membership in the Netherlands' Koninklijke Akademie van Wetenschappen; during 1947–52 he served as president of its section for natural sciences. He was also a member of many foreign scientific societies; his election as foreign associate of the U.S. National Academy of Sciences, as foreign honorary member of the American Academy of Arts and Sciences, and as foreign member of the Royal Society may be specifically mentioned. Microbiological societies, such as the British Society for General Microbiology and the Society of American Bacteriologists, were proud to count him among their honorary members. A recipient of several honorary degrees and other marks of distinction, he was perhaps most deeply touched when he was awarded the Copley Medal by the Royal Society.

Now his active and productive life has come to an end. Nevertheless, his contributions to science and society will continue through the work of his numerous pupils in various parts of the world. They will be aware of the great obligations which their association with A. J. Kluyver has engendered, and which implies the desire to perpetuate his way of life, to the benefit of humanity.

C. B. van Niel

Prof. J. M. D. Olmsted

James Montrose Duncan Olmsted was born of New England forbears at Lake City, Iowa, on May 21, 1886, and died at Berkeley, California, on May 26 just after his seventy-first birthday. Olmsted received an A.B. degree from Middlebury College (Vermont) in 1907 and four years later a B.A. from Oxford, where he was a Rhodes Scholar. He returned to the United States in 1911, served as professor of natural science at Shorter College, Rome, Virginia, and in 1912 became associate professor (later professor) of biology at Richmond College, also situated in Virginia, where he remained until 1915. During 1916–17 he held an Austin teaching fellowship (zoology) at Harvard, but he spent most of this period as a private in the U.S. Army, being demobilized in 1919 as a second lieutenant in the Sanitary Corps. After the War, J. J. R. Macleod made him assistant professor of physiology (later associate professor) in the University of Toronto. He remained there until 1927, when he went to the chair of physiology at the University of California, Berkeley. In 1931 he was appointed Senior Fellow to the Committee for the Relief of Belgium.

During his years as a Rhodes Scholar, Olmsted spent much of his time in France and became fluent in the language, and he also acquired an extensive knowledge of French literature and history. Being historically minded, it was natural that he should turn to historical writing in physiology; this resulted in a number of excellent papers and in three notable biographies: Claude Bernard (1939), François Magendie (1944), Charles-Edouard Brown-Séquard (1946), all three of which may be regarded as definitive, since no comparable studies of these important contributors to physiology have appeared in any language. Olmsted's scientific interests were wide and ranged from the special senses, the subject of his five excellent chapters in Macleod's "Physiology and Biochemistry of Modern Medicine" (fifth edition, 1927), to other aspects of neurophysiology and to carbohydrate metabolism, an interest inspired originally by Macleod. He published two of the pioneer papers on the action of insulin from the Toronto group—one under his own name on the effects of temperature, and another with A. C. Taylor on the action of insulin on oxygen saturation—both of which were submitted in April 1924 and appeared in the *American Journal of Physiology* for June of that year (69, 137 and 142).

Known as 'Olmie' to his closest friends, James Olmsted was by nature well poised but retiring, gentle in manner, the soul of kindness to students, and a quiet and most effective teacher. He took relaxation in music and painting, his medium in the latter having been chiefly water-colour. He was a member of the San Francisco Art Association, with which body he often exhibited. In a very real sense he was a physiologist in the best humanistic traditions of Foster and Sherrington. JOHN F. FULTON

NEWS and VIEWS

Pharmaceutics in the University of London: Prof. H. Berry

PROF. H. BERRY retires from his appointment as professor of pharmaceutics in the University of London and from his office as dean of the School of Pharmacy on September 30. He commenced his teaching career in 1919 after service in the Royal Fusiliers, Royal Engineers and Royal Garrison Artillery during the First World War. His first appointment was at the Robert Gordon's College, Aberdeen, but he soon transferred to the College of Technology, Birmingham, where he initiated and developed the Department of Pharmacy. In 1934 he joined the School of Pharmacy, University of London—then called the College of the Pharmaceutical Society—where he held a University readership in pharmaceutics and was appointed vice-dean. In 1937 he succeeded Prof. J. H. Burn as dean, and the title of professor of pharmaceutics in the University of London was conferred upon him in 1944.

It is in a large measure due to Prof. Berry's appreciation some twenty years ago of the impact of the advance of knowledge upon pharmacy that the new conception of pharmaceutics has been developed. He clearly saw that the day of empiricism was passing and that modern needs called for the application of science and engineering to the erstwhile pharmaceutical arts. Furthermore, he recognized that increasing costs and the development of the subjects of the degree to honours standards presented serious financial problems, and he succeeded in persuading the University of London and the University Grants Committee to accept the main burden of finance. This fundamental change was accompanied by a complete revision of the government of the School, which was consolidated when a Royal Charter was granted in April 1952. The new premises in Brunswick Square are, and will remain, a tribute to his work. His contributions to research have been mainly in the field of pharmaceutical microbiology, and many of the forty-five published papers will come to be regarded as classical contributions to the science. Prof. Berry, like all busy men, has found time to serve on many national and international committees, on the Pharmacopœia Commission and on the revision committee of the British Pharmaceutical Codex.

Prof. Edward Shotton

DR. EDWARD SHOTTON has been appointed to the chair of pharmaceutics at the School of Pharmacy, University of London, in succession to Prof. H. Berry. Dr. Shotton is a senior lecturer in pharmaceutics and a recognized teacher of the University. He qualified as a pharmaceutical chemist from the College of Technology, Birmingham, in 1933 and was appointed in 1934 as demonstrator in the College of the Pharmaceutical Society. In 1939 he joined the research staff of Burroughs Wellcome and Co. at Dartford, and later was appointed head of the Development Laboratories. In 1939 he obtained a London B.Sc. (Special) with first-class honours in chemistry, and in 1955 was awarded the degree of doctor of philosophy for a thesis entitled "Interfacial Tensions between Benzene and Sols of Arabic Acid and its Salts". He is a member of the University of London Board of Studies in pharmacy, and of the Boards of Examiners for the Pharmaceutical Society and the Universities of London and Manchester.

Dr. Shotton has made valuable contributions to the re-organization of the programme of training in pharmaceutics for the B.Pharm. degree along the lines envisaged by Prof. Berry, dividing the subject into three parts: general pharmaceutics, pharmaceutical microbiology and pharmaceutical engineering science. It is confidently expected that Dr. Shotton's long experience as a teacher and his experience in the pharmaceutical industry will enable him to weld these three parts into a living entity, and that he will continue to develop the scientific aspects of his subject and maintain it in correlation with the progress of pharmaceutical industry. Dr. Shotton's research interests have included problems of sterilization, the entrainment of liquid during distillation, the interfacial tension of solutions of arabic acid, the physical properties of granules which may affect adherence on compression, the stability of emulsions and emulsifying power, problems of formulation, etc.

Nuclear Power at the Imperial College, London : Prof. J. M. Kay

THE University of London has announced the appointment of Dr. J. M. Kay to the newly instituted chair of nuclear power at the Imperial College of Science and Technology. This will provide a focus in the College for study and interest in the fundamentals of nuclear power and in the engineering techniques involved. It will operate through post-graduate courses and research, and will maintain close liaison with all the Departments of Engineering and with those of Physics and Chemistry. Dr. Kay, who is thirty-five, graduated in the University of Cambridge, where he later held a University demonstratorship in chemical engineering. In 1952 he was appointed chief technical engineer of the Industrial Group of the Department of Atomic Energy at Risley, Lancashire ; since 1955 he has acted as a consultant in the field of nuclear power and in related industries.

University of Khartoum Bill

A BILL converting the University College of Khartoum into a University has been passed by both Houses of the Sudanese Parliament and submitted to the five Supreme Counsellors, in whom the presidential powers are vested, for their assent. The special relationship with the University of London, introduced in 1947, will cease, except in regard to students already registered, and the new University will award its own degrees and institute honours courses. Its budget for the next three years has been approved by the Sudanese Cabinet. When the Bill conferring university status comes into effect in the near future, Khartoum will be the first of the six overseas university colleges in special relationship with the University of London to assume university status. It will continue, however, to appoint external examiners from London as well as from other universities, and English will still be the language of instruction except in the Departments of Arabic and Sharia (Islamic) Law. The University will retain full autonomy, with executive powers vested in a council electing its own chairman and empowered to nominate a chancellor for appointment by the Supreme Council. Other Council members will include the vice-chancellor, treasurer, warden, members of the academic staff, nominees of Sudanese public and other bodies, and certain persons co-opted from the professions. The principal of the College, Prof. Michael Grant—on leave of absence from the chair of humanity in the University of Edinburgh—will become vice-chancellor. About three-quarters of the teaching staff are British, the remainder being mostly Sudanese (including three professors) and Egyptian. Appointments to twenty-four vacant posts have recently been offered. At the beginning of the new session there are expected to be 875 students in the University's seven faculties—an increase of about 170. It has developed from the former Gordon Memorial College, inaugurated in 1903 and extended to include the Higher Schools in various subjects (1945), and the Kitchener School of Medicine (1951), of which the final diploma is recognized by the Royal Colleges of Physicians and Surgeons.

Colonial Development Corporation

REPLYING for the Government in a debate on the Colonial Development Corporation in the House of Lords on June 20, Lord Lloyd, the Under-Secretary of State for the Colonies, said that there was no doubt that certain of the Corporation's activities, which the Secretary of State had been advised were *ultra vires* in relation to the Overseas Resources Development Act, 1948, were desirable from the point of view of the development of the Colonial territories. This legal opinion was disputed by the Corporation, and the Secretary of State for the Colonies accordingly proposed to introduce legislation to put the issue beyond legal doubt. A Bill had already been drafted, and the Government hoped to introduce such legislation before the end of the session. It was the Government's view that nothing should stand in the way of such legislation to validate actions which have been taken by the Corporation and are assumed to be *ultra vires*.

Atompraxis : New German Monthly Periodical on Atomic Energy

WITH the release at last year's Geneva Conference of much scientific and technical information concerning reactors and the peaceful uses of atomic energy, interest has been stimulated in many countries, and several new periodicals devoted to the study of individual branches of the subject have recently been launched. In Germany, where interest in nuclear science and engineering need no longer be purely academic, the new illustrated monthly periodical, *Atompraxis*, should prove most valuable in providing a medium for the dissemination and discussion of basic material and of new developments. The periodical is published by Verlag G. Braun, price DM 3.50 a number or DM 36 a year, and is obtainable in Britain through I. R. Maxwell and Co., Ltd., of London. The first number (pp. 40) contains articles on the use of radioactive isotopes in engineering, industry and hydraulics ; safety and protection problems arising in reactor projects ; the therapeutic use of the short-lived yttrium-90 isotope as a strong beta-emitter ; fundamentals, practice and problems of sterilization and preservation by gamma radiation ; and a review of the Geneva conference. One section is devoted to short summaries of important articles selected from other periodicals, and another to brief reports of the proceedings of conferences and society meetings. The editor, Dr. E. H. Graul, of Marburg, is assisted by Dr. K. Kamdl, of Linz, and Dr. A. Montens, of Essen.

Recent Donations to the Natural History Department of the Royal Scottish Museum, Edinburgh

DURING recent months the Natural History Department of the Royal Scottish Museum, Edinburgh, has been enriched by several important gifts. These include the large and important collection of cetacean remains formed by the late Sir William Turner, principal of the University of Edinburgh, which has been presented by the University ; the large collection of bird-skins, numbering nearly eight thousand, mainly from North Africa and Sicily, formed by the late Joseph I. S. Whitaker and containing Lord Lilford's collection, presented by Miss D. Whitaker, of Rome ; a small collection of bird-skins from Cyprus formed by Mr. G. F Wilson, of the Cyprus Secretariat, presented by Mr. H. F. Zetter on behalf of the English School, Nicosia ; the collection of bird eggs formed by the late Sir Maurice Denny and bequeathed by him to the Museum ; the collection of British Crustacea formed by the late Thomas Scott, of the former Fishery Board for Scotland, presented by Dr. C. E. Lucas, of the Scottish Home

Department; and a collection of marine shells from the New Hebrides and New Caledonia, made and presented by Mrs. Georgina Mills.

Electronic Computer for the Meteorological Office

APPROVAL has been given for the Meteorological Office to buy an electronic computer, and one has been ordered. The machine will be installed in the Napier Shaw Laboratory at the Central Forecast Office, Dunstable, and will be employed primarily on research into forecasting by numerical methods the space distribution of the height of selected isobaric surfaces which define the main features of the wind and temperature distribution up to some 10 km. above the Earth. On the basis of this information, the experienced forecaster can make the forecasts of wind and weather. Experience has shown the prediction of the future pattern of atmospheric structure to be one of the most difficult parts of forecasting; it is this part which electronic computers, by solving simplified forms of the dynamical equations of the atmosphere, can perform. Research into numerical forecasting has been conducted by the Forecast Research Division of the Meteorological Office for about eight years; but the Office has had to hire or borrow 'time' on the electronic computers belonging to others for actual trial of its methods. The computer will also be available for research into other complicated problems of meteorology, in which very heavy numerical work is involved.

Soaps as Polyelectrolytes

As a continuation of earlier seminars in the Chemistry Department of University College, London (*Nature*, 175, 670; 1955), Prof. J. J. Hermans, of the University of Leyden, gave a lecture on April 30 on polyelectrolyte properties of soaps. Debye's work (*Ann. New York Acad. Sci.*, 51, 575; 1949), dealing with the light-scattering of dilute soap solutions, was discussed, both the merits and the shortcomings of this treatment being demonstrated. Hutchinson's conclusions (*J. Colloid. Chem.*, 9, 191; 1954) neglect the fact that the system under consideration contains two solute components. Trap and Hermans (*Kon. Ned. Akad. Wet. Amsterdam*, B, 58, No. 2; 1955) carried out some accurate light-scattering measurements from which it follows that certain dilute soap solutions, in the presence of 0·05 *M* potassium chloride, contain rod-shaped micelles about 1000 A. long. This is consistent with earlier results of Debye and Anacker (*J. Phys. Coll. Chem.*, 55, 644; 1951). In the discussion, Dr. G. S. Hartley mentioned that the possibility of rod-shaped soap micelles had been considered by him in 1939, and Dr. J. H. Schulman referred to his recent work on surface tension. Other participants in the discussion directed attention to peculiar observations during the passage of soap solution through membranes. Finally, the question was discussed as to whether the intrinsic viscosity of soap solutions, determined at sufficiently low rates of shear with a Couette instrument, in conjunction with light-scattering experiments, might be helpful in estimating the size and shape of soap micelles. Such an approach would appear to be of interest, because of its success in the fields of other polyelectrolytes.

Rearing Locusts in the Laboratory

EVER since the days of T. H. Huxley, the standard introduction to the study of insect anatomy has been the dissection of the cockroach. Although large and easily obtainable, the cockroach is not an ideal insect for this purpose; the locust is better suited for teaching and for practice in elementary dissection. During recent years the locust has also proved increasingly useful for experimental work of many different kinds. The ease with which locusts can be reared in classroom or laboratory is not generally realized; it is therefore timely that the Anti-Locust Research Centre (1 Princes Gate, Kensington, London, S.W.7) should have produced a pamphlet, "Instructions for Rearing and Breeding Locusts in the Laboratory", by P. Hunter-Jones (pp. 9; 1956), which will be useful for both research workers and teachers. The easiest species to rear is the African migratory locust, *Locusta migratoria*, and most space is devoted to this; but the special requirements of the desert locust *Schistocerca gregaria*, the red locust *Nomadacris* and the Egyptian grasshopper *Anacridium* are briefly outlined. Copies of the pamphlet are obtainable on request from the Centre, which is often prepared to assist by supplying day-old hoppers for starting locust stocks.

Griseofulvin and Pathogenic Fungi

R. S. C. AYTOUN has contributed some interesting information on the effects of griseofulvin on actively growing hyphae of phytopathogenic species of *Botrytis*, *in vitro* and *in vivo* (*Ann. Bot.*, N.S., 20, 78, 297; 1956). *In vitro*, the reactions noted were slowing of the growth-rate, stimulation of branching, abnormal appearance of hyphal protoplasm, and loss of rigidity of the hyphal membrane in the region of the tip. The antibiotic is not translocated within the mycelium. *In vivo*, *Botrytis tulipae* was incapable of penetrating cell membranes in the stem of tulips watered with griseofulvin. The antibiotic was shown to delay or to prohibit the penetration of onion epithelium by *B. allii*, depending on concentration. The characteristic curling and stunting of hyphae caused by griseofulvin have both been observed to occur in plant cells.

Forestry Commission: Report for 1953–54

THE annual report of the Forestry Commission for the year ending March 1954 (pp. 177+8 plates. London: H.M.S.O., 1955; 6*s*. net) contains an introduction by Mr. James Macdonald, director of research and education, outlining the three sections in which forestry research is considered in the report. The first section deals with brief summaries of the main trend of work proceeding in the Research Branch of the Commission; the second deals with projects under investigation by universities and other institutions; and the third, a new section, comprises a series of papers by members of the research staff on subjects which have yielded sufficient information to be made public in this form, although often the importance of the inquiry must be considered as provisional. This is a most useful departure; so often during a piece of research work being undertaken a point is reached at which it would be useful for both the research worker and others to know exactly how far the investigation has gone, and yet this cannot be made available in a research report since the knowledge available is not of sufficient detail. A list is added to the report of the more important experimental areas in Great Britain, classified under subjects. As the report shows, contact has been maintained with universities and institutions engaged on research in forestry and related subjects, such as the Rothamsted Experimental Station and the Macaulay Institute for Soil Research. The Nature Conservancy, which is concerned with woodlands, has also been of great assistance. In order to secure liaison in fields of common interest, a small informal committee of representatives of the Nature Conservancy and the Forestry Commission has been established to discuss matters of research and investigation. The Research Branch of the Commission also takes an active part in the affairs of the International Union of Forest Research Organizations.

Rhizomorph Behaviour in *Armillaria*

S. D. GARRETT has investigated some of the factors which determine the vigour of the infection of potato tubers by the rhizomorphs of *Armillaria mellea* (*Ann. Bot.*, N.S., **20**, 78, 194; 1956). The growth of rhizomorphs of *Armillaria mellea* from small woody inocula through tubes of soil was characterized by a progressive decline in weekly growth increments. The initial growth-rate was related to the size of the inoculum food-base; the subsequent decline is attributed partly to depletion of nutrient reserves in the inoculum through fungal respiration and growth, and partly to competition for nutrients between the main growing apex of the rhizomorph and its subordinate branch apices. The vigour of infection of potato tubers by rhizomorphs from such small woody inocula increased with size of the inoculum, and decreased with increasing distance between inoculum and tuber. When the inoculum potential of *A. mellea* was low, the fungus was generally overtaken in the tuber tissues by soft-rotting bacteria, which prevented its further advance.

Zoological Nomenclature

As from November 9, 1956, the International Commission on Zoological Nomenclature will start to vote on the following cases involving the possible use of its plenary powers for the purposes specified against each entry. Full details have already been published (*Bull. Zool. Nom.*, 11, Pt. 11, 1956). (1) *Turbinella* Lamarck, 1799 (Cl. Pelecypoda), validation; (2) *Terrakea* Booker (F. W.), 1930, designation of type species for, and *brachythaerus* Morris, 1845 (*Productus*), validation of (Cl. Brachiopoda); (3) *Unio* Philipsson, 1788 (Cl. Pelecypoda), designation of type species for; (4) *Elaphe* Fitzinger, 1833 (Cl. Reptilia), validation; (5) *daea* Dampf, 1910 (*Palaeopsylla*) (Cl. Insecta), determination; (6) *Torquesia* Douvillé, 1929 (Cl. Gastropoda), designation of type species for; (7) Horniman (R. B.), January 1940, "Preliminary Descriptions of some new Birds", suppression. Comments should be sent as soon as possible to the secretary to the Commission, Mr. Francis Hemming, 28 Park Village East, Regent's Park, London, N.W.1.

Equal-Loudness Contours for Pure Tones

THE equal-loudness contours for pure tones heard binaurally have been redetermined at the Acoustics Section of the National Physical Laboratory, Teddington, by D. W. Robinson and R. S. Dadson (*Brit. J. App. Phys.*, **7**, 166; May 1956). Loudness is one of the few concepts which can be correlated with several aspects of the complicated subjective reaction to a sound and therefore provides a starting-point for measurement in such work. The relation between the loudness of a sound and its root-mean-square pressure and frequency for various waveforms and for binaural and monaural hearing is of interest not only in the understanding of the hearing mechanism and its reaction to pure and complex sounds, but also in the design of frequency-weighting circuits for such instruments as the 'sound-level meter' and in the calculation of loudness-levels from the spectrum analysis of sounds. Discrepancies exist between the previously published pure tone equal-loudness contours for free-field conditions (Fletcher, H., and Munson, W. A., *J. Acous. Soc. Amer.*, 5, 82 (1933), and Churcher, B. G., and King, A. J., *J. Inst. Elec. Eng.*, 81, 57 (1937)), and it was not possible to derive an acceptable standard. The new work reported by the National Physical Laboratory, which covers increased ranges of frequency and sound pressure and the effect of age and sex of otologically normal subjects, is a welcome redetermination. Although these results differ by up to 10 phons from the previous determinations, they are more regular with sound pressure and frequency, and the errors are estimated to be only about ±1 phon over the greater part of the work.

Royal Commission for the Exhibition of 1851: Awards for 1955

THE Royal Commission for the Exhibition of 1851 has awarded the following senior studentships for 1956 for research at the universities indicated: C. M. P. Johnson (Cambridge), nuclear physics at Cambridge; C. B. Reese (Cambridge), organic chemistry at Cambridge; Dr. M. W. Windsor (Cambridge), physical chemistry at Sheffield; A. J. Smith (Wales), geology at the University College of Wales, Aberystwyth. The Commission has also awarded the following overseas scholarships for 1956: Canada: C. B. M. Bailey (British Columbia), animal growth; C. Crowe (Western Ontario), physics at Cambridge. Australia: Dr. (Miss) B. I. H. Hall (Adelaide), physics at University College, London; A. L. Hunt (Adelaide), biochemistry at Oxford; S. P. H. Mandel (Sydney), mathematics at Cambridge; D. A. Levy (Sydney), theoretical chemistry at Cambridge. New Zealand: G. G. Pritchard (New Zealand), botany at Cambridge; W. D. Twose (New Zealand), physics at Cambridge. India: Dr. J. Jacob (Annamalai), zoology at Queen's College, Dundee, University of St. Andrews. Pakistan: F. Aziz (Lahore), radiochemistry at Cambridge.

University of Nottingham: Gifts

THE following gifts have been received by the University of Nottingham: £2,000 a year for five years from Imperial Chemical Industries, Ltd., towards the cost of building up a school of colloid science in the Physical Chemistry Laboratory; a research scholarship of £600 a year from W. Canning and Co., Ltd., of Birmingham, to be held in the Department of Metallurgy, for research in the field of metal finishing; £300 a year for three years from the Electro-Chemical Engineering Co., Ltd., of Woking, to the Department of Metallurgy towards the cost of a scholarship for research in metal finishing.

Physics of Nuclear Reactors

A CONFERENCE on "The Physics of Nuclear Reactors" arranged by the Institute of Physics was held in the Institution of Electrical Engineers during July 3–6. The programme opened with an address by Sir John Cockcroft, president of the Institute, on "Scientific Problems in the Development of Nuclear

Power". This was followed by lectures on the physics of advanced reactors, the zero-energy fast breeder reactor, effects of irradiation on the physical properties of solids, shielding, control, instrumentation, chemistry and metallurgy in a nuclear energy project, and the uses of reactors; Prof. R. E. Peierls gave an evening discourse on "Recent Developments in Nuclear Theory". Speakers came from Britain, the United States and Canada. An informal dinner was arranged for overseas visitors, who were also entertained at a Government reception. During the meeting there was an exhibition of books and of apparatus. The lectures, with the exception of that by Prof. Peierls, will be published as a supplement to the *British Journal of Applied Physics*; the programme of the conference includes full abstracts of the lectures.

Commonwealth–American Universities Conference

THE Commonwealth–American Universities Conference, at which university presidents from the United States representing the Association of American Universities will participate with vice-chancellors of United Kingdom and Commonwealth Universities, will be held this year in London and Birmingham during July 10–17 under the auspices of the Association of Universities of the British Commonwealth. The sessions in London will be opened by a reception on the evening of July 10 in the Senate House of the University of London at which H.M. the Queen Mother will be present as Chancellor of the University. Discussions will be held in London on the general question of "University Expansion in relation to Population Trends", with particular emphasis on the effect of the approaching 'bulge' in the university age-group in the United States and in various countries of the Commonwealth. The members of the Conference will visit Exeter on July 13 for the ceremony of installation of Mary, Duchess of Devonshire, as first chancellor of the new University. On the following day members will meet in Birmingham, where discussions will be held on a series of problems common to universities in Britain and the United States, such as the adequacy of school preparation for college and university students, the need for an expanding curriculum to meet new world needs, and the relationships of university administration to students, faculties and governing boards.

Royal Meteorological Society: Officers for 1956–7

THE following have been elected officers of the Royal Meteorological Society for the year 1956–57: *President*, Dr. R. C. Sutcliffe; *Vice-Presidents*, Prof. G. Manley, Sir Graham Sutton, R. G. Veryard and Dr. T. W. Wormell; *Vice-President for Canada*, Dr. D. P. McIntyre; *Vice-President for Scotland*, J. R. Atkinson; *Treasurer*, Dr. J. S. Farquharson; *Secretaries*, P. J. Meade, Dr. H. L. Penman, Dr. A. G. Forsdyke (*Librarian*) and Dr. G. D. Robinson (*Editor*).

Announcements

THE gold Albert Medal of the Royal Society of Arts has been awarded for 1956 to Sir Henry Dale, "for eminent service to science, particularly physiology".

AT the annual general meeting of the Marine Biological Association of the United Kingdom, held on June 27, Mr. E. H. E. Havelock, Dr. A. G. Huntsman and Dr. A. C. Redfield were elected honorary members of the Association.

THE Council of the Royal Society has awarded the Tropical Research Fellowship (Medical Sciences) to Dr. D. G. Jamison, of Corpus Christi College, Oxford, for his work on the histopathology of leprosy with particular reference to the relationship of the mycobacteria to cutaneous nerve fibres.

DAME CAROLINE HASLETT is resigning from the post of director of the Electrical Association for Women, which she has held since its inception thirty-two years ago.

DR. GERARD KLEIN, lecturer in theoretical physics in the Royal Holloway College, London, has been appointed senior lecturer in mathematics in the Royal Technical College, Glasgow.

THE following have been appointed to lectureships in The Queen's University of Belfast: L. J. Symons (geography), Dr. F. A. Lewis (inorganic chemistry) and R. Taggart (mechanical engineering).

THE following have been appointed to lectureships in the University of Birmingham: Dr. J. G. Valatin (mathematical physics), Dr. G. A. Doran and Dr. P. M. Rolph (physics), Dr. L. W. Poel (botany), Dr. G. T. Wright (electrical engineering) and Dr. J. J. Pick (industrial metallurgy).

THE British Iron and Steel Research Association will hold two 'open days' at its Sheffield Laboratories on September 6 and 7, for representatives of member firms.

THE United Nations Food and Agriculture Organization is holding an international meeting of inland fisheries workers in Helsinki during July 24–26, at which inland fisheries in relation to world food economy will be reviewed. The European member nations of the Organization will be sending representatives and, at the same time, biologists at the Thirteenth International Limnological Congress, which is being held in Helsinki during July 27–August 7, have also been invited to attend as observers.

A RESIDENTIAL course on rural studies, organized by the Institute of Rural Life at Home and Overseas, will be held at the Essex Institute of Agriculture, Writtle, near Chelmsford, Essex, during September 2–15. The course will be of a general nature, but tropical conditions will be included and the course should appeal to workers and students from overseas. The fee is £14. Application should be made not later than July 27 to the Secretary of the Institute, 59 Bryanston Street, Marble Arch, London, W.1, from whom further information can be obtained.

A SYMPOSIUM on "Recent Studies in Yeast and their Significance for Industry", arranged jointly by the Dublin Section and the Food and Microbiology Groups of the Society of Chemical Industry, will be held in Dublin at the Rupert Guinness Hall during September 17–18 (and possibly 19). The Biochemical Society, which is meeting in Dublin during September 14–16, is arranging sightseeing tours for the afternoon of September 15 and for the whole of the succeeding day; members attending the symposium can join these tours. Further information can be obtained from the honorary secretary of the Dublin Section of the Society of Chemical Industry, Dr. A. K. Mills, Arthur Guinness Son and Co. (Dublin), Ltd., Chemists' Laboratories, St. James's Gate, Dublin.

THE H. H. WILLS PHYSICAL LABORATORY

UNIVERSITY OF BRISTOL

DURING March 26–28 the Physics Department of the University of Bristol entertained several hundred guests with the object of showing both the teaching and the research work of the Laboratory to them. The guests included the Lord Mayor and Lady Mayoress of Bristol, professors of physics from other universities, industrial and government scientists, schoolmasters, and members of the academic staff of other departments of the University.

Apart from the numerous scientific conferences held in Bristol, including the British Association which met there last year, the Laboratory has not been on display in this way since its opening in 1927. The L-shaped building came into existence through the generosity of Henry Herbert Wills, and was designed by Sir George Oatley with the advice of Prof. A. M. Tyndall. Built on the hill where the old Royal Fort once stood, its extremely solid structure and embattled top well preserve the tradition of its name. It was originally intended to be only the first instalment of a group of University buildings, and with this in mind the north-western end was left unfaced, as it remains to-day. Grave doubts were, however, expressed at the time as to the wisdom of constructing so large a building with its two large lecture theatres, several smaller lecture rooms, library, workshops and research rooms, and all with ample provision for expansion. Three years after its opening the teaching and research staff numbered only eighteen, and many of the rooms were unoccupied. To-day, the staff number no less than seventy, and space is at a premium. Many research rooms have had galleries put in them (easily done because of the very generous ceiling heights) and special huts have been built to house both working low-temperature equipment and the mass of discarded apparatus characteristic of physics laboratories, which the occupants are not very likely to use again, but cannot bear to dispose of.

Throughout its existence, the Laboratory has been notable for the wide range of interest of its schools of research, and important contributions have been made in such different fields as magnetism, the electrical conductivity of gases, including accurate measurements of the mobility of gaseous ions, the spectroscopy of metals, the emission of soft X-rays, X-ray studies of long-chain hydrocarbons, and low temperatures. The result has been the development of a correspondingly wide range of experimental techniques and resources, and the work in progress to-day shows no less diversity. Most of the current research work, except that in theoretical physics, was displayed either by demonstrations of the working of the actual apparatus or by photographs and diagrams.

In optics, the interest is centred on high-aperture systems and interferometers for testing. A reflexion microscope of N.A. 0·95 (dry) and a meniscus Schmidt meteor camera of focal ratio *f*./0·78 and field diameter 56° were shown, both these instruments having already attracted considerable interest outside the Laboratory. The Laboratory also houses a commercial electron microscope which is available to all departments of the University, and is occasionally used also for work on problems encountered by local industries.

The early work of the Laboratory on low temperatures has already been mentioned, and the group engaged on this study is now one of the largest in the Department. Liquid oxygen and helium are purchased in bulk, and the Laboratory also has its own apparatus for producing liquid hydrogen and helium. The main subjects at present studied are paramagnetism of crystals at low temperatures, the superconductivity and thermodynamic properties of metals, the mechanical properties of solid argon, and properties of the liquid helium film.

The Department is well known for its work, both theoretical and experimental, on the solid state, and this interest was manifested in the exhibits of several different groups. Work on the growth of both metallic and non-metallic crystals was shown, and also on the structure of macromolecular substances such as polythene and nylon. Techniques for handling single crystals of silver halides have also resulted in the elucidation of many problems connected with photographic materials, and have also enabled the dislocation structure of a solid to be studied in a particularly direct manner.

The crystalline structure of thin evaporated metal films has been studied by X-ray techniques, and the effect of conditions of deposition and adsorbed gases on the electrical properties of these films has also been the subject of considerable experimental investigation. The mechanical properties of metals, particularly the mechanism of the development of fatigue cracks, and the investigation of the creep of strained single crystals, constitute the work of another group, the aim in this case being to produce results capable of theoretical interpretation rather than of immediate technical use.

Techniques for the electronic measurement of very small strains were also in evidence in work on ferroelectrics, in which hysteresis loops not only of polarization against field but also of mechanical strain against either could be displayed oscillographically. Attempts are also being made to produce an 'artificial' dielectric material of extremely high permittivity. In all these solid-state studies the Laboratory is fortunate in being well equipped with X-ray diffraction apparatus, including single-crystal and powder cameras, a stabilized X-ray unit with an output constant to better than 1 per cent, and a Geiger-counter diffractometer for X-ray fluoroscopy.

A comparatively recently developed interest in the Department is the study of mineral separation, which centres mainly on the flow properties of fine sands or slimes suspended in water. Apparatus for bulk separation has been devised, and also an analytical tool, the 'mechanized vanning shovel', which reproduces some of the movements used by Cornish miners in assessing the separable mineral content of ores.

QP309

The largest research group, and probably the best known, is devoted to the study of cosmic rays and is housed at the top of the building. The two most important techniques demonstrated were the production and flying of high-altitude balloons, and the processing and examination of nuclear emulsions, both of which have been greatly advanced as a result of work by the Bristol group. The importance of this work both in the study of the nature of cosmic-ray primaries, and in the investigation of nuclear events at energies higher than can be obtained even with the largest accelerators, is too well known to require elaboration here.

The more routine activities of the Laboratory, such as in the teaching laboratories, workshop and glass shop, were on view and excited considerable interest, and in these matters the Department can congratulate itself on being very well staffed and equipped. As a further diversion to visitors, films were exhibited periodically in the large lecture theatre. These films were made by members of the Laboratory and illustrated work on cosmic rays, glass blowing and crystal growth.

For its growth from small beginnings to its present state, the Laboratory owes an enormous debt of gratitude to Prof. A. M. Tyndall, first holder of the Henry Overton Wills chair of physics (1919–48). In this office he was succeeded by Prof. N. F. Mott (1948–54) and then by Prof. M. H. L. Pryce (1954–). The second professorship, the Melville Wills chair, has been held by the late Sir J. E. Lennard-Jones (1927–32) and Prof. N. F. Mott (1933–48), and the present incumbent is Prof. C. F. Powell (1948–). From time to time a third professor of physics has been appointed—Prof. S. H. Piper (1951–53) and Prof. F. C. Frank (1954–). A recent addition to the distinctions of the academic staff was the election this year of Dr. J. W. Mitchell to the fellowship of the Royal Society.

Comments and letters received from the visitors by the organizers seemed to confirm that the open days, although involving a considerable amount of work, have been successful in bringing the activities of the Laboratory to the attention of its guests in an interesting and agreeable way. D. F. GIBBS

CARNEGIE INSTITUTION OF WASHINGTON

REPORT FOR 1954–55

YEARBOOK No. 54 of the Carnegie Institution of Washington* covers the year July 1, 1954–June 30, 1955, including Dr. Vannevar Bush's final report as president and the reports of departmental activities and co-operative studies, with a bibliography of publications of the Institution and of the president in addition to those appended to the departmental reports. At the Mount Wilson and Palomar Observatories two major studies of the Andromeda nebula were completed during the year: an intensive study of the high-luminosity variables, including the cepheid, the long-period, the semi-regular and the irregular types; and a systematic search for novæ during two observing seasons, in which the detailed light curves of thirty novæ were measured and, for the first time, definitive statistical information was obtained on the absolute luminosities at maximum, types of light curve and the frequency of these novæ. A third major project was the establishment of a precise, photoelectrically determined magnitude-scale, extending down to the faintest observable stars in several areas distributed in such a way that at least one of the areas is always visible in the night sky for comparison. The project has now provided standards for use throughout the range of the Hale telescope. The programme concerned with setting up photoelectric standard-magnitude sequences has also been completed, and the study of the internal motions in planetary nebulæ continued, as well as spectroscopic observations of the Cassiopeia radio source and a spectroscopic observation of the colliding pair *NGC* 1275 in the Perseus cluster of galaxies. A new grating spectrograph was put into service at the Cassegrain focus of the 60-in. telescope, and a new stellar template magnetometer is being developed to increase the efficiency of observations of stellar magnetic fields, depending on the use of a template of the spectrum of the star to be investigated.

The Joint Committee on Image Tubes for Telescopes is attempting to develop a promising type of image converter for mass production, in which a very thin film is stretched across the end where the phosphorescent screen would otherwise be located; this film permits the electronic image to be formed astride the tube while the high-quality vacuum is preserved. An attempt is also being made to develop a special type of thin-film converter capable of withstanding full atmospheric pressure, thus avoiding the complications of the vacuum charger required in the first converter.

The Department of Terrestrial Magnetism, using the 'Mills cross' array of antennæ, has made the interesting and unexpected discovery of a variable 22-Mc./s. source of small dimensions in the constellation Taurus. A comprehensive series of measurements on the distribution of hydrogen clouds in several sectors of our galaxy indicates that our solar system is near the inner edge of a local arm, and that this arm is not circular about the centre of the galaxy but is strongly inclined. Observations have also been made on the intensity distribution of the emission from the 'quiet' Sun and on the low-frequency radio emission from several of the most intense sources in the sky, with the view of differentiating between thermal and other possible mechanisms producing these radiations. In a seismic expedition to the Rocky Mountains in the summer of 1954, unequivocal evidence was obtained that the sharp boundary between the crust and mantle of the Earth lies at the same depth under the Colorado Plateau in Arizona and New Mexico as under the coastal plain in Maryland and Virginia, and later in the summer the same result was obtained under the mountains of Utah. Encouraging progress was made in determining the extent to which the history of the changes in the Earth's magnetic field can be traced in geological time, and an expedition to Arizona and New Mexico showed that the rocks of the south-west of the United States give about the same location for the magnetic pole in Permian time as is indicated by the rocks of Great Britain. In the programme of isotope dating for ancient minerals, age studies of minerals in the Quartz Creek (Colorado) area have demonstrated a pattern of consistency among the rubidium–strontium ages and also among the potassium–argon ages of the micas from this region. Studies have also been made of toroidal magnetic fields in the ionosphere, of the daytime enhancement of the initial phase of magnetic storms at Huancayo, and the investigation of nuclear energy-levels by the method of Coulomb excitation with alpha-particles was continued.

* Carnegie Institution of Washington. Year Book No 54 (July 1, 1954–June 30, 1955), with Administrative Reports through December 9, 1955. Pp. xxxix+9+311+3 plates. (Washington, D.C.: Carnegie Institution of Washington, 1956.) Cloth, 1.50 dollars; paper, 1 dollar.

A major shift in biophysical work was made from the study of the synthesis by cells of small units like amino-acids to the organization of these units into the biologically active molecules of protein and nucleic acid. The kinetics of protein formation in bacteria and yeast have been studied and the specific adsorption of amino-acids as a first step in their incorporation into proteins observed, while experiments have also been made on the role of peptides in protein synthesis.

The Geophysical Laboratory has completed a broad study of the system copper–iron–sulphur and has discovered a strong dependence of (solid state) inversion temperatures on very slight excesses of silver or tellurium in the compounds Ag_2Te and Ag_5Te_3. Extensive X-ray studies of single crystals of digenite have been completed, and preliminary experiments made on methods of dissolving sulphide ores *in situ*. In the hydrothermal synthesis of albite, small but significant variations in lattice parameters have been discovered as a function of temperature of crystallization alone. In statistical petrography the emphasis has been primarily on the theory and technique of modal analysis, while a systematic investigation has been made of the effect of cæsium and thallium on the system $K_2O.Al_2O_3.6SiO_2—H_2O$, using special radioactive tracer techniques with the view of obtaining the fundamental data needed on the distribution of trace elements. Much attention has been given to all three amphibole groups as well as to feldspars and micas.

The Department of Plant Biology has further developed a new way of measuring the absorption of light of different colours by the functional pigments in living plant material and in solutions of the extracted pigments, and the method has already been utilized in studying the photochemistry of chlorophyll. Progress is being made in the isolation of the protochlorophyll holochrome in increasingly smaller units. Experiments on the transformation of protochlorophyll to chlorophyll have continued in aqueous and glycerol extracts of various etiolated plants, all the extracts so far prepared showing particles in a dark-field microscope. Studies of the rate of re-formation of protochlorophyll in leaves illuminated and then returned to darkness have shown that the rate of re-formation accounts for the rate of formation of chlorophyll in illuminated plants for the first two hours. Investigations in etiolated barley seedlings of the precursors of protochlorophyll which contain magnesium have indicated that the extra magnesium accumulated in illuminated plants is contained in an acidic fraction and that from one-third to two-thirds of the total protochlorophyll in barley is of the phytol-free form. The range-grass programme has continued. and the chromosome numbers of all but one of the hybrid *Poa* lines used in the regional tests are now known. The study of the biosystematic structure of the aquatic plant family Lemnaceae has continued, and experiments in general taxonomy have been designed to elucidate the complex genetic and environmental relations between and within wild species of plants. A new planting of the second generation of yarrow from coastal and alpine environments is providing information about the hereditary constitution of the parental races. Studies on the rate of growth under laboratory conditions of different species and strains of the miniature *Lemna* have indicated little difference in the optimum temperature for growth between strains of the same species from different climatic regions, the differences being between species rather than between races of the same species. This lack of distinct racial differences within the species is strikingly at variance with the findings in species of other plants grown in soil.

The report of the Department of Embryology includes a brief survey of the work of the Department during 1913–55 whereby the description of the human embryo has now been completed by the definitive description of those representing the first four or five days of development. A comprehensive investigation of the development of the human diaphragm has clarified the anatomical defects underlying diaphragmatic hernia. Studies continued of the uterine lining, especially of its blood vessels, in relation to the phenomena of menstruation, and a preliminary account has been published of work on the passage of the sugars across the monkey placenta, using a method which promises to be very useful in studying fœtal physiology.

In the Department of Genetics electron-microscope studies of third-instar salivary-gland cells of *Drosophila* have afforded evidence of the polytone nature of the chromosomes, the subsidiary strands having a diameter of about 500 A. and being arranged in a hierarchical assembly of intertwined pairs of pairs. Investigations of the action of cytochrome *c* in reducing basophilia of tissue sections indicate that basicity *per se* is not the determining factor since lysozyme, another basic protein, does not reduce basophilia of tissue sections, whereas hæmoglobin, another hæmoprotein, does. All three proteins increase staining with acidic dyes. Although a considerable degree of purification of calf-spleen deoxyribonuclease has been effected, crystallization has not yet been achieved, and the marked changes in the mode of action with purification suggest that several enzymes capable of degrading deoxyribonucleic acid may be present.

Chemical studies of bacteriophage have provided further evidence of the genetic role of viral nucleic acid. The substance that initiates viral infection is at least 95 per cent pure nucleic acid, and this increases in infected cells before viral-precursor protein begins to form. Substances such as chloramphenicol that inhibit protein synthesis do not interfere with the formation of nucleic acid, and nucleic acid 'purified' in this way behaves like normal virus precursor. Accordingly, nucleic acid is not synthesized inside a viral membrane and can function without associated protein. New evidence has been obtained that, in the transduction of *Salmonella* clones, incorporation of the genetic specificity of the donor strain into the genotype of the recipient usually occurs in the single daughter cells within one or two divisions after infection. Genetical analysis of short regions of the chromosome complex of *Salmonella typhimurium* have shown that all the known tryptophan, cystine and methionine loci are closely linked. A high concentration of amino-acids during the critical period corresponding to the first third of the first division after irradiation appears to be a major requirement for the production of induced mutants, and evidence has been obtained in the transformation of genetic markers in *Salmonella* that mutations are frequently induced during the preparation of the donor material. Other work on controlled mutation in maize and the organization of cellular materials is reported in some detail.

ITALIAN SOCIETY FOR GEOPHYSICS AND METEOROLOGY

FOURTH GENERAL ASSEMBLY

THE fourth General Assembly of the Società Italiana di Geofisica e Meteorologia (Genova) was held at the University of Genoa during April 5–8. The convention was opened by the president, Prof. M. Bossolasco, who welcomed the delegates to the Assembly. A large number of papers ranging over a wide number of topics was presented.

Prof. A. Defant (Innsbruck) delivered the opening lecture, on "Recent Developments in the Theory of Ocean Currents". Referring to the classical theory due to V. Ekman for a homogeneous ocean, he gave an account of the recent contribution due to H. Stommel and W. Munk, pointing out the objections directed to it and its limitation. He then discussed the theory of ocean currents due to G. Neumann, which uses as surface of reference that deduced for the Atlantic from the observations of the expedition *Meteor*. Prof. Defant showed that this new theory gives a possible explanation of the intensification of ocean currents on their west coasts. Reference was also made to some work by Charney on the formation of narrow currents on these coasts.

Prof. Perri (Turin) spoke on "The Slow Surface Wave and its Seismological Significance in a Limiting Case". This referred to a slow surface which was discovered by the author, the theory of which he developed in 1954. Prof. Perri recalled its main features and attributed the fact that the velocity of the wave is intermediate between that of the Rayleigh waves and Love waves to an abnormal dispersion.

Prof. A. Giao (Paris) presented a paper on "The Behaviour of the Advection Vector of the Perturbations of the Vertical Vorticity in the Free Atmosphere". After discussing the definition of the advection vector, Prof. Giao went on to consider applications to the atmosphere. By means of the observed temperature fields and wind between the equator and the poles (from sea-level to the 20-km. level) one can deduce the mean field of the advection vector of the perturbations and compare it with the mean wind in the field. This leads to the explanation of many empirical facts and gives the limits of the region of 'long waves'. The second part of the paper dealt with the derivation of a generalized equation for the vertical vorticity by a simple transformation of the equation of pressure variation in Prof. Giao's theory of perturbation.

"The Oscillations of the Natural Radioactivity of the Air in the Northern Alps, and Their Significance" was the title of a paper by Dr. R. Reiter (Munich). Dr. Reiter has found from many measurements of the air of the Zugspitze (2,600 m. above sea-level) that the greatest radioactivity is associated with southerly currents. This is considered to point to a dependence on the nature of the geological formations traversed by these winds, the formations containing granite and orthogneiss. Dr. Reiter also discussed the variations of the radioactivity of the air as a function of other meteorological factors.

A paper by Dr. C. Mennella (Naples) dealt with "The Reliability of the Presumed Normal Values of the Rainfall in Italy". Considering various series of rainfall measurements for the past hundred years or so, Dr. Mennella attempted to appraise the reliability of the mean values relative to quinquennial, decennial and longer periods. This enables one to estimate the degree of variability and instability and to deduce to what extent they are inadequate to represent the specific characteristics of the phenomena.

Dr. W. Hesse (Leipzig) spoke on "The Hydrogenic Balance of Plants" and on "The Results of Measurements made on Various Plants as Functions of Meteorological Factors". Dr. Hesse pointed out that the water system of cultivated plants is very complicated and is influenced by various external factors; on the meteorological side, several methods have been evolved to assess evaporation and transpiration of plants. In the vegetation period 1950, 1953, 1954 and 1955, Dr. Hesse used the newly developed Klein lysimeter in Leipzig, and from 1954 onwards a transpirograph and a measuring apparatus consisting of six different Klein lysimeters with which it was possible to assess the water content of plants.

Prof. O. Burkard (Graz) proposed a formula for the moving ionization of the F_2 layer in Europe. He showed that the squares of the critical frequencies $(f_0F_2)^2$ measured at European stations in the morning may be represented by the empirical formula:

$$(f_0F_2)^2 = K\left(\frac{\cos\chi}{\cos^2\varphi}\right)^x \cos^2\varphi$$

where χ is the zenith angle of the Sun, φ the geographical latitude of the station, x depends on locality, K is a constant depending on the locality and probably on the intensity of the solar ionizing radiation.

The communications from Prof. P. G. Piccardi and Dr. R. Cini (Florence) were presented by Prof. Bossolasco. These related to "The Action of an Electromagnetic Field of Frequency 10 kHz. on a Chemical Test" and "The Problem of the Influence of Atmospherics". Experiments showed that Prof. Piccardi's chemical test is influenced by an electromagnetic field of frequency 10 kHz. (kc./s.) and that it is probable that the variations observed during this test are due to variation in solar electromagnetic radiation as well as atmospherics due to lightning discharges.

Prof. V. Ferraro (London) gave an account of the present state of theories of magnetic storms. He pointed out that an atmospheric-current theory such as has been proposed by Vestine is unlikely to prove correct since on this theory it seems difficult to account for such distinctive phenomena as sudden commencements, auroral zones and other features which point rather to an influx of solar corpuscular streams in the upper atmosphere as the cause of these phenomena.

Dr. K. Rawer (Neuershausen b. Freiburg) gave an introductory talk to the general discussion on the International Geophysical Year. Dr. Rawer discussed in particular preparations made for the study of ionospheric recordings, absorption, 'winds', back scatter and whistlers. The discussion that followed related particularly to questions of interest to the Italian participants of the International Geophysical Year.

In a paper on "The Harmonic and Anharmonic Constants for the Tides at Palermo, Milazzo, Lipari and Cagliari", Dr. S. Polli (Trieste) said these are determined for periods of 26 months in the case of Palermo, and shorter periods for the other stations, by using the British Admiralty method developed by Doodson. The monthly and seasonal variations in the tides are determined separately, so as to examine any seasonal variations of the constants. A second paper dealt with wind-bores in the ports of Trieste and Venice; it appears that this wind-bore traverses the gulf of Venice without change of direction, lateral expansion and with little loss of speed.

Prof. H. Berg (Cologne) dealt first with "The Velocity Profile in Rivers"—an attempt to express the vertical velocity gradient of rivers by a logarithmic law using certain ideas of Prandt concerning turbulent flow over rough surfaces. In a second paper, on "Examples of Trivial Correlations in Solar Terrestrial Relationships", Prof. Berg examined two such examples: Farthing's experiment, which led him to conclude that a period of intense coronal radiation is followed by a penetration of cold air over the Earth; and an investigation by Abbott, who claimed that the solar constant is considerably lowered on days of intense geomagnetic storms. Prof. Berg showed that the results in both cases are only the outcome of faulty mathematical reasoning.

Prof. G. Berbesconi (Genoa) considered the "Partial and Total Representation of an Ellipsoid on the Sphere". Starting from the principle of the minimum energy of deformation of an elastic ellipsoidal geographical network, Prof. Berbesconi determines a relationship between the ellipsoid of gyration and the local spherical surface in the neighbourhood of the oscillation point up to a radius of 250 km. He next examines various functions the extremals of which give a good representation of the whole ellipsoid on the sphere and define a new latitude which he considers useful for the construction of geographical globes.

Dr. I. Dagnino (Genoa) considered the "Frequency of Cyclones and the Distribution of Cloud in the Mediterranean", using the synoptic charts for all the days during the period 1946–55. For the case of the region of maximum frequency, Dr. Dagnino has examined and discussed the principal atmospheric and meteorological factors giving rise to these cyclones—in addition to the seasonal factors.

Prof. Bossolasco (Genoa) spoke on some work he has done with collaborators on "The Atmospheric Electric Potential in the Layers close to the Ground". The result of a series of observations (with Drs. Dagnino and Romagnone) to determine the variation of the atmospheric electric field near ground-level showed a decrease of the potential gradient from a height of 1 m. to 2 m., and a further decrease at a height of 3 m. The variation at discrete potential-levels confirms electrically the presence of a boundary layer near the ground. A second communication dealt with the "Measurement and Continuous Recording of the Salinity of the Atmosphere". The apparatus used for the purpose is one developed by F. Meda, based on the principle of collecting the radioactivity by passing the air through water.

Prof. M. Cutolo (Naples) spoke on "The Measurement and Behaviour of the Geomagnetic Field at the Lower Border of the E-layer". He described how this can be effected by taking the mean of the frequencies of the two maxima in the gyro-interaction curve and pointed out that the measurements of the geomagnetic field would be very accurate. Prof. Cutolo also spoke on "The Effects of Demodulation in the Ionosphere"; this method also provides an alternative method of measuring the geomagnetic field in the E-layer.

"Micropulsation in the Geomagnetic Horizontal Force and in Telluric Currents" was the subject of a paper by Dr. K. Burkhat (Munich). Dr. Burkhat pointed out that although the close connexion between geomagnetic variations and telluric currents has been known for more than a century, it has only recently been possible to decide which of the two phenomena is the cause and which the effect. At large distances from the electrodes, and in the case of small periods, the respective phases are in good accord. But for small periods (diurnal variation) and close to the electrodes, one finds a definite difference in the phase of the currents with respect to the geomagnetic variations. The difference in phase can be explained as due to the effect of resistance and reactance, since we now know that every telluric current connected with geomagnetic variation is due to induced currents. Dr. Burkhat then considered the statistics of pulsations and noted that the frequency curve for pulsations with periods of about 30 sec. coincides very nearly with the variation of maximum electron density in the E- and F_1-layers.

Prof. M. Matschinski (Paris) next spoke on "Problems of Geochemistry". He confined himself to what he described as the geographical aspects of geochemistry—which problem he formulated as that of finding the relationship between the chemical and geographical traits of given regions. As an example, he considered volcanic regions in the form of arcs; he recalled that he has already found a relationship between the density and the radius of curvature of the arcs. Prof. Matschinski showed several graphs with the view of demonstrating a statistical interdependence between geographical traits and certain chemical characteristics of rocks of the regions considered; for example, the mean percentages of the oxides of silicon, aluminium, calcium, magnesium, sodium, potassium and iron. These results were obtained from more than two thousand analyses.

The prize for meteorology offered by the Society was awarded to Prof. A. Giao and M. Ferreira for their paper "Introduzione alla climatologia dinamica dell'America Settendrionale, del Nord-Atlantico e dell'Europa". The following officers were elected for the period 1956–59: *President*, Prof. M. Bossolasco, *Council*, Profs. Aliverti, Lovera and Ranzi; *Secretary*, Dr. I. Dagnino.

V. C. A. FERRARO

MEMBRANE PHENOMENA

FARADAY SOCIETY DISCUSSION

THE Faraday Society held a general discussion on "Membrane Phenomena" in the University of Nottingham during April 10–12. Nearly two hundred scientific workers attended the discussion, the first of its kind to be held in Nottingham. The president, Mr. R. P. Bell, took the chair for the whole of the meeting, and the proceedings were opened by the sending of a message of greeting to Prof. F. G. Donnan, a founder-member and past-president of the Society, who is well known for his work in the field of membrane equilibria.

The discussion proper was preceded by the Spiers Memorial Lecture, given on this occasion by Prof. T. Teorell (Upsala), whose subject was "Transport Phenomena in Membranes". Prof. Teorell indicated how his own interest sprang originally from biochemical studies on hydrochloric acid in the stomach. He outlined structural studies on cell membranes, showing slides of striking electron micrographs taken by F. S. Sjöstrand. He stated that theories must explain the five phenomena of ionic transport, membrane potential, electrical conductivity, ionic distribution equilibria, and the potential gradient and spatial distribution of ions within the membrane. In this connexion he discussed the achievements of four theories: those of the porous membrane, the homogeneous membrane, the energy-barrier model, and the fixed-charged membrane model. He pointed out how concentration gradients within a membrane may be in the reverse direction to the overall gradient between the two bulk solutions on each side of the membrane, leading to anomalous transport. He surveyed most ably the whole range of phenomena from the collodion membranes of Michaelis to the recent results of the Cambridge physiology school, concluding with reference to his own recent model which shows rhythmic variations of potential.

The general introduction was given by Prof. G. Scatchard (Massachusetts), who briefly outlined the programme to be followed, emphasizing the key part to be played by the thermodynamics of irreversible processes. T. L. Hill's (Bethesda) paper showed how the McMillan–Mayer solution theory, applied to the membrane equilibrium problem, leads directly to a value for the osmotic pressure. A combination of this theory with the classical Donnan method in certain instances leads to the membrane potential. R. Schlögl (Göttingen) divided total particle fluxes into those relative to the local centre of gravity, and a convection common to all particles, and showed that the latter may play an important part in membranes with an appreciable water permeability.

M. Nagasawa and I. Kagawa (Nagoya) found that the slope of the straight line connecting membrane potential and the logarithm of the ion activity for an ion-exchange membrane is less than RT/F, which they explained by abnormal ion activities within the membrane. F. Bergsma and A. J. Staverman (Delft), discussing a similar discrepancy for bi-ionic potentials, have found it particularly marked for hydrophile membranes and suggested water transport as the cause. G. Scatchard and F. Helfferich (Massachusetts and Göttingen) have found the abnormally high potentials observed in various cells with cation exchange membranes to be most marked when ions of different valence are present and to be markedly reduced by suitable stirring. They attribute the observations to a preference of the membrane surface for divalent ions. F. Helfferich (Göttingen) discussed the effects of Nernst diffusion films adherent to the membrane on its permeability. R. Neihof and K. Sollner (Upsala and Bethesda) have calculated rates of exchange of ions from membrane potentials of bi-ionic systems, demonstrating ionic selectivities approaching those observed in biological systems.

G. Manecke and H. Heller (Berlin-Dahlem) discussed the separation of non-electrolytes from electrolytes using an ion-exchange membrane, a problem also of interest to T. S. Mackie and P. Meares (Aberdeen), who compared sorption isotherms and diffusion-rates of ethanol in 'Zeocarb 315'. The ethanol is salted-in to the membrane, and it appears that two-thirds is in solution in the water swelling the membrane and free to diffuse, the remainder being adsorbed on the polymer chains.

J. W. Lorimer, E. I. Boterenbrood and J. J. Hermans (Leyden) have investigated membranes of viscose and sodium carboxymethyl cellulose, carrying out six measurements—specific conductivity, two transport numbers, two diffusion coefficients, and permeability—in order to permit evaluation of the six phenomenological coefficients of the thermodynamic theory. A. Despic and G. J. Hills (London), using membranes of cross-linked polymethacrylic acid, have subtracted electrosmotic flow from total flow, thus obtaining the flow due to solvated counter-ions. The latter quantity leads to a value of 9 ± 1 for the solvation number of sodium ion within the membrane. H. P. Gregor and D. M. Wetstone (Brooklyn) dealt with selective transport across sulphonic and carboxylic cationic membranes.

K. S. Spiegler, R. L. Yoest and M. R. J. Wyllie (Pittsburgh) considered the electrical potentials arising across porous plugs of ion-exchange materials, separating two solutions of the same electrolyte. In dilute solutions such plugs give almost perfect membrane potentials; but in concentrated solutions, conductance occurs largely through liquid in the pores, and the potential difference approaches the liquid-junction potential. The results are shown to be relevant to the suspension effect observed in pH measurements on suspensions and gels using a combination of glass and calomel electrodes. T. R. E. Kressman and F. L. Tye (London) showed how the transport numbers of sodium and chlorine ions in certain ion-exchange membranes decrease with increase in current density, an effect attributable to concentration diffusion. D. Hutchings and R. J. P. Williams (Oxford) considered how far cation-exchange membranes are suitable for analytical use. They have found conditions on the whole to be unfavourable, equilibrium potentials being reached only slowly, and in any case being often lower than those expected on thermodynamic grounds.

The last session was devoted to the properties of biological membranes. D. D. Eley and D. G. Hedge (Nottingham) examined the interaction of protein solutions with lipoid monolayers by a development of the Schulman–Rideal technique. Increases in surface pressure were interpreted to show the formation of a first sublayer of fully uncoiled protein chains, and a secondary layer consisting possibly of native protein. A. Rothstein (Rochester, N.Y.) concluded from studies of yeast cells that the cell surface is a "multimembrane compartmentalized structure". There is an outer barrier impermeable to proteins and holding enzymes such as saccharase and phosphatase. Within this there is a second membrane impermeable to anions and bivalent cations but permeable to potassium and hydrogen ions. Finally, there is a barrier impermeable to potassium and hydrogen ions, and containing metabolic pumps for phosphate and potassium ions. Dr. Rothstein outlined the evidence supporting this model: exchange reactions with radioisotopes are playing a big part in this kind of work.

W. D. Stein and J. F. Danielli (London) defined 'facilitated diffusion' as involving a specific structural relationship between the membrane and the diffusing species. As a model for the permeability of red-blood cells to glycerol, they consider a pore, possibly of protein, containing hydrogen-bonding groups that complex with the glycerol and lead to the observed kinetics, which are of the saturation or Michaelis–Menten type. Various glycols and alcohols were shown to be competitive inhibitors for the diffusion, and copper a non-competitive inhibitor. Freda Bowyer and W. F. Widdas (London) discussed the same problem for glucose and red-blood cells, considering in particular the kinetics of inhibition by dinitrofluorobenzene, which appears to be a fourth-order reaction. P. Mitchell and J. Moyle (Edinburgh) have found the specificity and kinetics of phosphate transport in *Staphylococcus aureus* to resemble those for enzyme-linked reactions, and suggested that the enzyme-substrate complex forms the carrier for the facilitated diffusion. In the closing paper, R. D. Keynes and R. H. Adrian (Cambridge) described how in resting nerve or muscle the membrane is 25–100 times more permeable to potassium ion than sodium ion, the inside of the fibre being negative to the outside. As the action potential arrives, the membrane changes so that sodium ion becomes the more permeable ion, the inside of the fibre now becoming positive. There is no model to date which will account for the observation that the ratio of the permeability of sodium ion to that of potassium ion is linked to the electrical polarization of the adjacent membrane.

There was a lively discussion on many of the papers, and a number of contributors sought to show how ion-exchange systems can lead to a selective action on different cations. On the whole, it seemed that there is still something of a gap between the achievements of the physical chemist and the needs of the biologist with his complex systems; but it seems clear that this general discussion, and the published account which will appear in due course, should do much towards the further closing of this gap in the future. It is clear that the Faraday Society continues to provide a unique forum for the development of the border-line sciences.

ROYAL COMMISSION ON AWARDS TO INVENTORS

FINAL REPORT

THE fourth and final report of the Royal Commission on Awards to Inventors* concludes the record of the Commission's work. Besides listing decisions of the Commission since November 9, 1952, it discusses certain aspects of the more important of the 115 claims considered since the issue of the previous report. Only nine claims were dealt with under Head 1 of the Warrant during the period, and the Commission from the outset indicated its reluctance to deal with patent claims where the validity of the patent was seriously challenged. Several claims have consequently been referred to the Courts and other claimants have elected to have their claims considered under Head 3, that is, under the exercise of the Crown's bounty in granting an *ex gratia* award. By far the majority of claims heard by the Commission have been brought by such claimants, who have waived, or have not possessed, legal rights to support their claims. This procedure cannot be applied to claimants possessing patent rights who, after the period to which their claim relates, have assigned their patents to a third party. Normally, at the request of the Crown, the Commission has taken into account, in estimating the utility of the invention, its possible future use by the Crown as well as the past use. In a claim by J. R. Geigy S.A. and the Geigy Co., Ltd., relating to dichlorodiphenyltrichlorоethane, the patents covering the invention had, at the date of hearing, been transferred to a newly formed company which was not a party to the claim, and the claimants undertook either to amend the claim by joining the patentees or to obtain an undertaking safeguarding the Crown from any further claim.

From time to time it has been urged on the Commission that exceptionally large use of an invention should be taken not merely as an important factor but as the predominant factor in determining the quantum of an award. It was on this principle that, in view of evidence showing the highly effective use of rockets in the later stage of the War, both in regard to material and to morale, the Commission, notwithstanding the heavy discount which the status of the claimants involved, recommended an award of £5,000 for the invention of a loose-charge rocket motor. In regard to novelty and originality of invention, the material question which has weighed with the Commission has been whether it has been the earlier or later publication or communication which has in fact led to the practical use of the invention by the Crown; nor has the fact that the claimant has patented his invention abroad, and thereby knowledge of the invention has been made available to an enemy country, necessarily disqualified the claimant from receiving an *ex gratia* award. Accordingly, the Swiss firm of J. R. Geigy S.A. was not disqualified from receiving an award in respect of the exceptional usefulness of DDT as a means of safeguarding the health of British troops; in the same way, notwithstanding the fact that the information contained in the late Prof. N. A. V. Piercy's earlier papers dealing with the mathematical basis of the design of aerofoil sections had become common knowledge among aeroplane constructors, the Commission, in view of evidence that his subsequent confidential communications to the Air Ministry were of permanent value for the construction of aerofoils, recommended an award.

The Commission has occasionally, as in connexion with the Pritchard principle for constructing bomb-sights, recommended an award where the inventive merit of the contribution consisted mainly of mathematical or theoretical calculations. Claims by employees of Crown contractors have generally been treated on the principle that, if the invention was made in fulfilment of the employee's duty to his employers, he should look to the firm he serves for an *ex gratia* reward for such services. The Commission was, however, able to treat the status of the claimants in the project known as Pluto and the inventors of the cavity magnetron as substantially the same as that of research workers directly paid by the Crown, since at the time they were lent or seconded to a government department for carrying out the experimental work which led to the invention. An award could be recommended to the inventor of the winged target or pilotless aircraft for towing behind aircraft because the company employing the inventor had waived its claim as patentees against the Crown in favour of the inventor. An award of £2,500 was recommended in respect of the disk seal triode in spite of some dubiety as to the validity of the claim, in view of some ambiguity in the contract in force and of the merit and extensive usefulness of the technique, particularly in blind firing from ships.

The gratuitous offer to the Crown and its contractors of the free user of a patented invention does not necessarily disqualify the owner of the patent from afterwards qualifying for an *ex gratia* award; but the Commission has held that surgical or medical discoveries, in accordance with the recognized practice of the medical profession, become available for use of the Crown in the same way as for any members of the public. The only award recommended under Head 4 of the Warrant was for a claim in respect of the Sommerfeld track.

THE CATTLE EGRET

AN Old World bird which is a constant companion of cows has become established in the United States in the past fifteen years. Unknown there before its first appearance in Florida in 1942, there are now approximately two thousand birds in that State, according to Alexander Sprunt, jun., of the National Audubon Society (Smithsonian Institution News Release, April 13).

The bird is *Bubulcus ibis*, the cattle egret, which has been well known for many years in southern Europe, Africa and the Middle East. It is a small white egret with dark-brown feet and yellow legs and bill and is most remarkable for its strange, constant association with cattle. The close proximity to cattle is little short of astonishing. It keeps pace with the animal continually, usually close by the head, but sometimes near the fore or hind feet and occasionally under the abdomen. When an insect is disturbed, the bird darts out, catches it and returns. Now and then it reaches up and takes something from the body of the cow, or its legs. At times, the cow may be seen to push the bird aside with its muzzle, but appears not to object otherwise to the immediate closeness of its satellite.

A peculiar and unexplained characteristic of the bird is its habit of weaving the head and neck from side to side. A bird will suddenly stop feeding, stand perfectly upright, and weave the upper part of the body.

It feeds chiefly on grasshoppers and crickets. This may explain its fondness for cattle, which disturb these insects in the grass while grazing.

How the cattle egret got to the New World, especially the United States, is difficult to explain. It was first observed in British Guiana in 1937, but did not appear in the United States until five years later.

The cattle egret population is concentrated in Florida; but stray specimens have been observed as far north as Maine, and even Newfoundland, and inland to Chicago. Sprunt believes that a few pairs may have been blown over the Atlantic by wind currents.

SEA-BIRDS IN SWEDEN

IN 1950, regulations came into force in Sweden prohibiting the shooting of sea-birds during the early months of the year. The Swedish Institute of Forest Zoology has now completed investigations to show the effects of these regulations (Bull. Roy. Sch. Forestry, Stockholm, Sweden, No. 22; 1956). These show that everywhere the eider has increased substantially in numbers, while stocks of the velvet scoter were generally unchanged. This species usually arrives at the breeding places so late that it is scarcely affected by the legal spring shooting. There is, accordingly, a substantial difference between the eider and the velvet scoter in this respect, which supports the assumption that the prohibition of spring shooting—which applied only to the eider—had a salutary effect on the stock of that species.

The general trend regarding the stocks of Swedish sea birds since the new regulations were introduced has led to the following conclusions.

There is little possibility of distinguishing between male and female birds. Even if differentiation were possible, the male bird in the spring would still be essential for breeding. The risks of wounding birds in the large spring flocks are greater than those in the autumn shooting of migratory birds.

Birds are being shot which have been produced at other places and, at this time of the year, are returning to their production areas. This shooting cannot be motivated by game protection.

Although the amended regulations of 1950 have been of some benefit—indeed, of very appreciable benefit in the case of the eider—further review of the problems of spring shooting is now required.

The question of restricting spring shooting rights to the coastal population should be carefully considered, regardless of whether the shooting is done in public or private waters.

Should this prove impracticable, it is recommended that a general ban on spring shooting be introduced and that the coastal population be compensated by granting them prolonged autumn and winter shooting rights.

Permission might also be given for the limited shooting of male birds in production zones having well-ordered sea-bird protection. A certain amount of spring shooting along the migratory routes beyond the skerries but outside the production zones proper might be permitted as a transitional measure.

EVENING INSTITUTES IN BRITAIN

THE most popular studies pursued at evening institutes are those offering instruction in household handicrafts. More than a quarter of the student body registered, totalling nearly one and three-quarter million, are women taking classes in cooking, catering, home-furnishings, needlework and similar subjects for the improvement and decoration of the home.

This significant change in the character of evening classes is revealed by a Ministry of Education survey designed to help local education authorities, principals of institutes and teachers to meet the changing needs of young people and adults for purposeful leisure-time study and occupation*.

The change in public taste, and also in social conditions over a period of twenty years or so, is reflected in subject and attendance figures given. Between 1930 and 1952, the numbers of students studying vocational subjects in evening institutes declined considerably, while the numbers taking non-vocational subjects, such as art, music, handicrafts, dancing, and so on, increased. During this period vocational studies have to a great extent been transferred from evening to day work, largely as a consequence of the increasing readiness of employers to give young people time off during the day for study. The full-time work in technical colleges also increased greatly over the period.

---

* Evening Institutes. Ministry of Education Pamphlet No. 29. (London: H.M.S.O.) 3s. net.

The new emphasis on 'do-it-yourself' subjects has been accompanied by a change of character in the student body as a whole. Formerly, there were more men and women between the ages of eighteen and twenty-one attending senior vocational courses than any others. Now, the preponderant group is composed of students attending leisure-time classes, the majority of them women over the age of twenty-one.

Besides purely domestic subjects, older housewives and recently married couples take leatherwork, weaving, lace-making and basketry. So popular is the demand that the scope of subjects is steadily being extended to cover health, household management, parentcraft, and those aspects of sociology and psychology which affect the well-being of the family.

The number of young people between fifteen and eighteen attending evening classes is higher than it has ever been, though fewer now enrol in 'grouped' vocational courses. This feature is more noticeable in the south than in the industrial midlands and the north-west, where family tradition and pressure by employers still encourage attendance. Over the country as a whole the predominant type of class is the recreational one in which young people and grown men and women are to be found working together. Most of the work consists of making furniture for the home.

Full-time teachers are rare. Of 41,834 teachers engaged in 1952, only 67 were full-time assistants, and only about a third of them were professional teachers by day. The bulk of staff engaged were non-professional people with special knowledge or skill who became teachers in the evenings. The number of such instructors is increasing.

In addition to the expected kinds of instruction, classes dealing with local industries are not uncommon. There is a class on boat-building in a Thames-side town, for example; navigation is studied in a Devonshire fishing town; and welding courses are provided in a small midland town remote from a technical college. In urban evening institutes a common class is the owner-driver and car maintenance class. The instructor is often the proprietor of a local garage. A similar type of specialized class is radio and wireless, generally taken by a local radio trader.

The provision of classes in prisons and Borstal institutions is a development which has taken place since the Second World War. There are now classes in sixty-four establishments in England and Wales. In large establishments a separate institute can be formed; for smaller places the classes are usually attached to the nearest evening institute. Subjects of instruction are much the same as in the normal evening institute.

The survey examines in detail current practice in the organization and teaching of the arts, vocational courses, physical activities and subjects in the more formal curriculum provided by every evening institute. A suggestion is offered that courses and groups might with advantage be started in 'popular' science. Though it is not certain that teachers could be found for such an innovation, or that the public response would make it worth while, it is thought to be an experiment well worth trying.

HIGH-VOLTAGE PAPER ELECTROPHORESIS OF NON-VOLATILE ORGANIC ACIDS AND THEIR MIXTURES WITH AMINO-ACIDS

By Dr. D. GROSS

Research Laboratory, Tate and Lyle, Ltd., Keston, Kent

SURPRISINGLY few results of successful separations of organic acids (excluding fatty acids) by electrophoresis have been published, although on theoretical grounds the utilization of the variation of mobilities with dissociation constants would appear to be promising.

Earlier attempts[1] were limited in scope and success, and the separations of only a few free acids or derivatives of acids have been described so far. Recently, Berbalk and Schier[2] reported on a more elaborate investigation of the mobilities of a series of acids under the conditions of paper electrophoresis. In a study in this laboratory of the electrophoretic behaviour of organic acids at high potential gradients, we have found that, under the conditions chosen, even small existing differences in mobilities could be exploited for clean, rapid and reproducible separations, which, as the positions taken up by the various acids are mostly different from those on chromatograms, affords a useful complementary method for the detection and identification of many acids. In general agreement with Berbalk and Schier, we found a fairly good correlation between dissociation constants and migration rates, that is, mobility being directly proportional to K, and electrolyte solutions of about pH 2 to be most suitable for separations. Raising the pH of the solution increased the mobilities of some acids but also led to multiple spots. To effect a separation between two acids, their dissociation constants must vary by a factor of, at least, 2, although several exceptions have been found.

In further development of the technique[3], the cooling system has been improved by the introduction of aluminium alloy cooling plates of 1 in. thickness, with water flowing through grooves in the precision-ground, closely fitting plates, thus ensuring a better contact and heat transfer. With cooling water (tap water) of 9° C., energy of up to 3 W./cm.^{2} has been satisfactorily dissipated. The construction of a bigger power unit capable of delivering up to 150 m.amp. at up to 12,000 V. has made the application of potential gradients of up to 240 V./cm. to a strip of an effective length of 50 cm. possible. The dielectric strength of insulating films of polythene ('Telcothene') of a thickness of 0·015 in. has been found sufficient under these conditions. The exact measurement of voltages greater than 3,000 V. proved difficult, and certain corrections for lack of precision had to be made. A pneumatic uniform pressure device added since has greatly improved the evenness of migration.

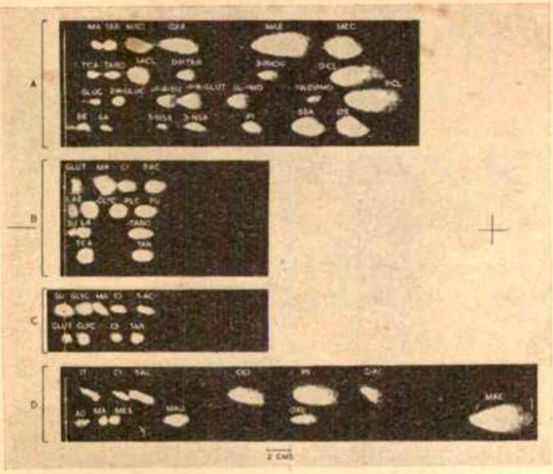

Fig. 1. Electrophoresis of non-volatile organic acids

Organic acids: *AD*, adipic acid; *BE*, benzoic acid; *C-AC*, *cis*-aconitic acid anhydride; *CI*, citric acid; *CIO*, citraconic acid; *D-CL*, dichloracetic acid; *D-HTAR*, dihydroxytartaric acid; *FR-DIPHO*, fructose-1-6-diphosphate (barium salt); *FU*, fumaric acid; *GL-PHO*, D-glucose-1-phosphate (potassium salt); *GLUC*, gluconic acid; *GLUT*, glutaric acid; *GLYC*, glycollic acid; *I-CL*, *iso*citric acid lactone; *IT*, itaconic acid; *α-K-BU*, α-keto-butyric acid; *2-K-GLUC*, 2-keto-gluconic acid; *α-K-GLUT*, α-keto-glutaric acid; *LA*, lactic acid; *LAE*, lævulinic acid; *MA*, malic acid; *MAE*, maleic acid; *MAO*, malonic acid; *M-CL*, monochloracetic acid; *MEC*, meconic acid; *MES*, mesaconic acid; 3-*NSA*, 3-nitro-salicylic acid (2-hydroxy-3-nitro-benzoic; 5-*NSA*, 5-nitro-salicylic acid (2-hydroxy-5-nitro-benzoic); *OX*, oxalic acid; *OXA*, oxalacetic acid; *OXU*, oxalsuccinic acid; 3-*PHOG*, 3-phosphoglyceric acid (barium salt); *PI*, picric acid; *PLC*, pyrrolidone-carboxylic acid; *PY*, pyruvic acid; *SA*, salicylic acid; *SSA*, sulphosalicylic acid; *SU*, succinic acid; *T-AC*, trans-aconitic acid; *TAR*, tartaric acid; *TARO*, tartronic acid; *TCA*, tricarballylic acid; *T-CL*, trichloracetic acid

Conditions: (*A*) 120 V./cm., 7·4 m.amp./cm., Whatman No. 3 *MM*. 4 × 22½ in. strip, 0·75 *M* formic acid, *p*H 2·0, mean temperature of cooling water 10° C., 20–50 μgm. of each compound (according to strength of acid) applied 3 in. from cathode end, ½ hr. (*B*) 100 V./cm., 5·2 m.amp./cm., 0·75 *M* formic acid + 1 *M* acetic acid (1 : 1) mixture, *p*H 2·25, 1½ hr. (*C*) 180 V./cm., 7·2 m.amp./cm., *p*H 2·25, ¾ hr. (*D*) 200 V./cm., 13 m.amp./cm., *p*H 2·0, ½ hr.

The results obtained are illustrated by Fig. 1, which shows the position of forty-two organic acids after electrophoresis at various potential gradients for varying periods of time. Both solutions of formic acid and of mixtures of formic acid and acetic acid were used. To remove the volatile acids, the strips were dried at about 90° C. for 5 min. and then exposed to a stream of cold air for 1–3 hr., depending on the grade of paper used. The thicker Whatman No. 3 *MM* paper usually required 2½–3 hr. for removal of residual acid, whereas for Whatman No. 1 1 hr. was sufficient. Removal is essential when a *p*H indicator is used to reveal the separated non-volatile acids. A 0·1 per cent solution of bromo-phenol blue in 96 per cent ethanol saturated with sodium carbonate proved to be satisfactory, showing the acids as yellow spots or bands on a blue background. In general, there are four main groups of acids: (1) those with high dissociation constants (values at 25° C.) and thus moving fastest in the electrical field, typically represented by oxalic acid ($6{\cdot}5 \times 10^{-2}$); (2) those moving at a slightly slower rate, represented by maleic acid ($1{\cdot}5 \times 10^{-2}$); (3) those moving at somewhat less than half the speed of oxalic acid, represented by pyruvic acid (3×10^{-3}); and (4) the slow-moving acids, of which the fastest is represented by fumaric acid ($1{\cdot}0 \times 10^{-3}$) and the slowest by succinic acid ($6{\cdot}6 \times 10^{-5}$). In the latter group, glyoxylic acid ($4{\cdot}6 \times 10^{-4}$) can be cleanly separated from glycollic acid ($1{\cdot}49 \times 10^{-4}$). The alkaline hydrolysate of *iso*citric acid lactone yielded one major constituent, possibly *iso*citric acid, separable from citric acid. The time required for separations was ½–1½ hr., depending on voltage applied and types of acids present.

It was noticed that at *p*H 2 all amino-acids examined, being below their iso-electric point and thus positively charged, moved well away to the cathode, whereas the organic acids, being still negatively charged, moved to the anode. This offered a possibility of dealing with both groups of compounds, which very often occur together, on a single electrogram. The procedure adopted was to spray one half of the strip with ninhydrin, heat it and reveal the amino-acids present, and then spray the other half with bromo-phenol blue to reveal the non-volatile organic acids. Only taurine moved too short a distance away from the starting line and had, in case of doubt, to be checked by another run. The displacement of the weaker organic acids towards the cathode is, of course, due to electro-endosmotic and electrolyte flow effects and is mainly a function of voltage applied, time of run and original position of sample. Various mixtures of twenty different organic acids and twenty-one amino-acids were distinctly separated into their individual components at potential gradients of 160–240 V./cm. and within short periods of time, ranging from 13 to 30 min. per run. Some of the results are shown in Fig. 2.

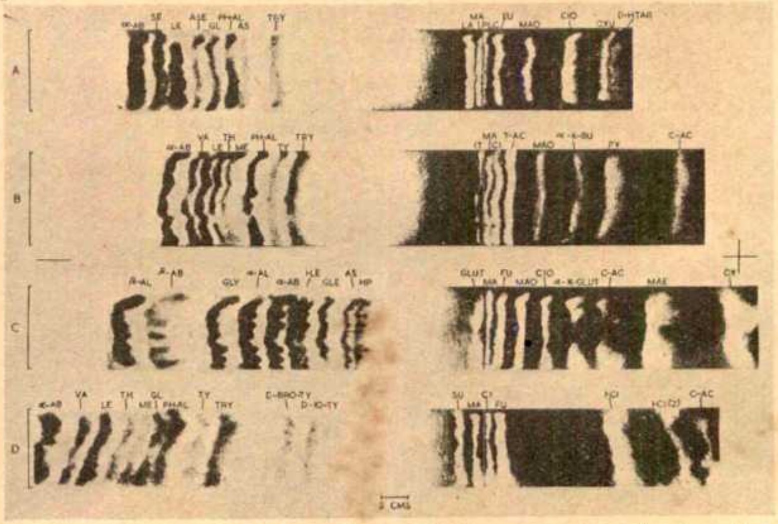

Fig. 2. Electrophoresis of mixtures of non-volatile organic acids and amino-acids

Organic acids as in Fig. 1. Amino-acids: *α-AB*, α-amino-butyric acid; *β-AB*, β-amino-butyric acid; *α-AL*, α-alanine; *β-AL*, β-alanine; *AS*, aspartic acid; *ASE*, asparagine; *D-BRO-TY*, di-bromo-tyrosine; *D-IO-TY*, di-iodo-tyrosine; *GL*, glutamic acid; *GLE*-glutamine; *GLY*, glycine; *HP*, hydroxyproline; *I-LE*, *iso*leucine; *LE*, leucine; *ME*, methionine; *PH*, phenylalanine; *SE*, serine; *TH*, threonine; *TRY*, tryptophan; *TY*, tyrosine; *VA*, valine

Conditions: (*A*) 160 V./cm., 10·5 m.amp./cm., Whatman No. 3 *MM*. 2½ × 22½ in. strip, 0·75 *M* formic acid, *p*H 2·0, 20 μgm. of amino-acids and 50 μgm. of organic acids applied 8–10 in. from anode end, mean temperature of cooling water 12° C., ½ hr. (*B*) 160 V./cm., 10·2 m.amp./cm., *p*H 2·0, 27 min. (*C*) 200 V./cm., 13·8 m.amp./cm., *p*H 2·0, 13 min. (*D*) about 240 V./cm., 13·7 m.amp./cm., *p*H 2·0, water temperature 9° C., 24 min.

The range of acids applied is limited only by the length of the paper strip. The full range of acids requires a strip of a length of 80–100 cm. *Iso*leucine contained a well-separated contaminant of slightly lower mobility, and *iso*citric acid lactone had a contaminant of higher mobility. Tentative experiments have been started in connexion with an investigation into the possibilities of two-dimensional electrophoresis by extraction of the bands after the first run, concentration and re-application as spots for the second run. In this conjunction it was found that the position of glutamine in borate buffer of *p*H 9·2 is not as shown before[3], presumably due to decomposition of sample, but between starting line and asparagine. The separation of aspartic acid, glutamic acid, asparagine and glutamine is thus made possible.

Thanks are due to Mr. H. C. S. de Whalley, director of research, for encouragement, Dr. F. A. Isherwood for the gift of a sample of *iso*citric acid lactone, Mr. R. W. Butters for technical assistance, Mr. S. D. Gardiner for help in the design of the electrical power unit, and to the directors of Tate and Lyle, Ltd., for permission to publish this communication. NATURE OF "CHALK HEATH" SOILS

By R. M. S. PERRIN
School of Agriculture, University of Cambridge

IN certain areas on the Chalk of Great Britain, particularly on the South Downs, there are found shallow, strongly acid soils with *Erica cinerea* or *Calluna vulgaris* as invading or locally dominant species. Co-existing with these typical calcifuges are calcicoles, such as *Poterium sanguisorba*, which are mainly rooted in the underlying chalk. These unusual associations have been described by Tansley[1], who refers to them as "Chalk Heaths".

In a study of weathering and soil-formation on the English Chalk, briefly reported elsewhere[2], it was found important to decide whether these "Chalk Heath" soils consisted of decalcified and highly leached residues from chalk or whether they represented thin drift deposits. This question cannot be answered by field-examination alone. The soils are usually full of angular and nodular flints, as would be expected in a true chalk soil, and pass sharply into the underlying chalk. Further, their depth is generally consistent with the probable rate of accumulation of chalk insoluble residues since the cessation of solifluxion at the end of the Pleistocene. On the other hand, in some cases the soils appear to be too deep and too deficient in flints to be truly residual from chalk.

The mechanical and mineralogical compositions of several representative "Chalk Heath" soils were therefore compared with those of the acetic acid–insoluble residues from a number of chalks. Special attention was paid to soils from Manor Farm Down, Cocking, West Sussex, and Lullington Heath, East Sussex, where particularly good examples of "Chalk Heath" vegetation occur.

The mechanical composition of the small amount of insoluble residue from Upper and Middle Chalks varies little from place to place and is typified by the summation curve in Fig. 1 (I). Clay is invariably the dominant component, and there is no evidence of sorting in the sand grades. A soil truly derived from the residue of such chalk is typically found to give a mechanical composition curve as shown in Fig. 1 (II), the shape of this curve being mainly determined by the mechanical weathering of flint in the sand fractions. If, however, the amount of flint in each grade is estimated by microscopic examination, the curve can be re-drawn on a flint-free basis and is then of the form shown in Fig. 1 (III). These curves illustrate the fact that in soils truly derived from chalk some destruction of clay takes place as well as comminution of flint. As would be expected, there is no evidence of any sorting in the sand grades.

The "Chalk Heath" soils, on the other hand, give summation curves, typified by Fig. 2 (I), which indicate a high degree of sorting with a predominance of particles with diameters in the region of 0·03–0·04 mm. Comparison of these curves with those of loesses and 'brickearths' of recognized aeolian origin (for example, Fig. 2 (II) and (III)) strongly suggests that these soils are mainly derived from wind-blown material. Sorting and deposition by water would appear to be ruled out by the topographical situations of the heaths on the crests or slopes of escarpments.

On the other hand, while the soils correspond closely to some British brickearths, they differ from typical North American or European loesses in carrying higher proportions of clay and sometimes,

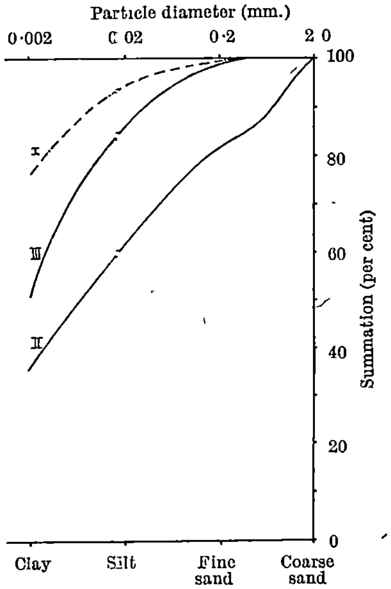

Fig. 1. Insoluble residues from a chalk and from its derived soil. (I), Upper Chalk, Hambledon Hill, Dorset; (II), Upper Chalk soil, Hambledon Hill, Dorset; (III), Upper Chalk soil, Hambledon Hill, Dorset, curve redrawn on flint-free basis

In accordance with common usage in pedology, the summation curves only show the composition of material less than 2 mm. in diameter. Larger particles are collectively referred to as 'stones' but not invariably, of sand grains greater than 0·066 mm. in diameter. This extra sand, however, always consists of flint, which is apparently weathering *in situ*, since it occurs only in the coarser sand grades and as stones. In soils where the flint content is appreciable, a composition curve is obtained as in Fig. 3 (I); but if this is replotted on a flint-free basis, it assumes the form of (II), the upper part of which corresponds closely to that for a loess. The high clay contents of the soils can be explained in various ways. The most likely explanation is that the local wind-blown dusts carried appreciable amounts of clay in the form of soil aggregates of fine-sand dimensions and that this clay has been re-dispersed during the process of mechanical analysis.

The sand fractions contain very rich assemblages of heavy minerals, including green and blue amphiboles, zircon, rutile, anatase, ilmenite, tourmaline, garnet, apatite, kyanite, epidote, sillimanite and zoisite, together with a few grains of a variety of other minerals. Such assemblages are far too rich to have been derived from the insoluble residue of chalk, and the presence of blue amphibole strongly suggests that the material is derived from Pleistocene deposits. It must therefore be considered to be of Pleistocene or Post-Pleistocene age.

The clay fraction of a "Chalk Heath" soil is made up of kaolinite and dioctahedral vermiculite. This differs markedly from the clay in the insoluble residue of chalk, which consists of illite and dioctahedral montmorillonoid. However, experience with soils truly derived from chalk and from various tills in East Anglia has shown that it is usual for montmorillonoid to weather to kaolinite and for illite to alter to dioctahedral vermiculite. The kaolinite–vermiculite assemblage appears, in fact, to be a typical weathering product in free-draining soils in Britain. The mineralogy of the clay fraction thus unfortunately provides no evidence as to the origin of the soil.

From the available evidence it thus seems likely that the "Chalk Heath" soils originate from the deposition of wind-blown material on flinty pavements, produced by the local weathering of chalk, on sites from which Clay-with-flints and other Tertiary deposits had previously been stripped by peri-glacial or normal erosion. This hypothesis is supported by the practically identical shapes of summation curves (on a flint-free basis) for soils from widely separated localities and by the occasional presence adjacent to "Chalk Heaths" of deeper deposits, again with the same mechanical composition but with a lower proportion of flint stones.

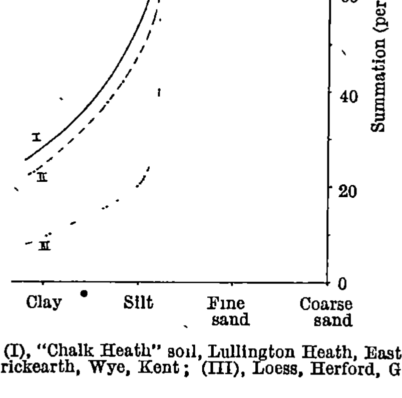

Fig. 2. (I), "Chalk Heath" soil, Lullington Heath, East Sussex; (II), Brickearth, Wye, Kent; (III), Loess, Herford, Germany

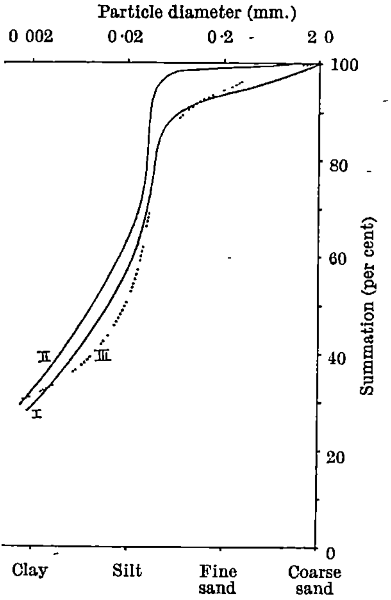

Fig. 3. (I), "Chalk Heath" soil, Manor Farm Down, West Sussex; (II), "Chalk Heath" soil, Manor Farm Down, West Sussex, curve redrawn on flint-free basis; (III), Topsoil overlying Clay-with-flints, Combe Hill, south-west of Wendover, Bucks

If this suggested origin be correct, it would be expected that topsoils giving composition curves of the same type would be widespread and would occur on various geological formations. Such soils have now, in fact, been located on the Chalk in the Yorkshire Wolds and on Clay-with-flints in Savernake Forest, Berkshire. Deposits of a slightly different type but also with a marked concentration of particle diameters in the region 0·03–0·04 mm. have been found overlying the Chalk on the Berkshire Downs, red Clay-with-flints on the Chilterns (see Fig. 3 (III)) and Carboniferous Limestone in Derbyshire. It therefore seems likely that careful mechanical analysis might reveal thin deposits of similar loess-like material in many soils in Britain which have not been too greatly disturbed by long-continued agriculture.

It would clearly be of great interest to know when the material was laid down. Cornwall[3] has recently shown from archæological evidence that loess was probably deposited in England as late as the Bronze Age. It is hoped that in due course it will be possible to date the deposits on the "Chalk Heaths" using similar methods.

The assistance of Dr. M. Black, of the Sedgwick Museum, Cambridge, in the execution and interpretation of heavy mineral analyses is gratefully acknowledged. Details of the complete investigation will be published elsewhere.

Impulsive Radio Signals from the Planet Venus

RADIO signals of an impulsive or burst-like nature which appear to come from the planet Venus have been detected at the Ohio State University at a wave-length of 11 metres. The observations were made with an interferometer antenna consisting of two colinear arrays of six horizontal half-wave-length elements one-quarter wave-length above ground. Each array is backed up by a reflector element, which, with the ground, forms a corner reflector. The arrays are separated by 426 ft. along an east–west axis. The receiver operates a pen recorder with a time constant of about one-quarter second.

Twice on May 23 and once on May 30, 1956, intense signals were observed when Venus drifted through the main antenna beam. On each occasion the signals were recorded for a period of two to three hours. They appear on the recorder tape as a succession of randomly spaced sharp spikes each representing a burst of short duration (1 sec. or less). The appearance somewhat resembles records of signals received from Jupiter[1]. On each of the three records the envelope of the spikes shows an interferometer lobe pattern in close agreement with one to be expected for a radio source at the position of Venus. The likelihood of confusion with the Sun or other planets is remote, since these were well separated in angle from Venus. Radio sources such as Cygnus *A*, Cassiopeia *A* and Taurus *A* were also well removed. Furthermore, they exhibit a different appearance on the tape and have fixed, instead of changing, celestial co-ordinates.

On all the three records the bursts are observed to pass through peaks spaced about 90 min. apart, at which times they are most frequent and intense. The record of May 23 is of particular interest in this respect since a period of activity was observed between 1300 and 1500 E.S.T. and again between 1900 and 2100, both periods showing similar peaks of activity 90 min. apart. The Sun set at 1947 E.S.T. There is some indication of activity between 1500 and 1900, but Venus was near the edge of the main beam during this period.

In about three months of searching for signals from Venus since February 1, 1956 (no observations were made during April), the only periods of intense activity observed were on May 23 and 30. Possible indications of activity from Venus were noted on February 15 and March 6 but with less certainty. It may or may not be significant, but on May 17 and 26 there were large solar flares. These dates are six and four days, respectively, in advance of May 23 and 30, on which days signals from Venus were observed.

The peak power flux-density of the bursts of signals from Venus have often been recorded at several times the value of the Cygnus *A* radio source at the same frequency (26·7 Mc./sec.). Assuming that Cygnus *A* has a power spectrum proportional to the wave-length, the peak radiated radio-power flux-density of a burst from Venus is:

$$38 \times 10^{-24} \times 9{\cdot}4 \times 2{\cdot}5 = 8{\cdot}9 \times 10^{-22} \text{ W. m.}^{-2} \text{ (c./s.)}^{-1}$$

where 38×10^{-24} W. m.$^{-2}$(c./s.)$^{-1}$ is the value for Cygnus *A* observed[2] at 250 Mc./sec., 9·4 is the spectrum ratio, and 2·5 is taken as the Venus to Cygnus *A* ratio at 26·7 Mc./sec. on May 23. Actually, the Cygnus *A* spectrum may be flatter than assumed, but compensating this effect the peak burst of power may be higher than recorded since the receiver time constant is one-quarter second and the burst may be of considerably shorter duration. The distance of Venus on May 23 was 0·4 astronomical unit. Assuming that the Venus source radiates isotropically and neglecting the loss through any ionosphere which the planet may have, the peak power in a burst from Venus is about 40 watts per cycle per second of band-width. This is about 0·003 of the value observed for a burst from Jupiter.

If one assumes, in the absence of information about the spectrum of the signal, that the power is constant over a 10-Mc./sec. band-width, the integrated peak radiated radio power of a burst from Venus is 4×10^8 watts (or 400 megawatts). However, if the spectrum is more like that for terrestrial lightning, this may be too low by a factor of about 10, making the value 4×10^9 watts. The total peak power in a terrestrial lightning stroke has been estimated at 10^{13} watts or more[3]. Assuming a conversion efficiency to radiated radio power of 0·001 yields 10^{10} watts of radiated radio power for a terrestrial lightning stroke. This is somewhat larger than the probable value for Venus. Thus, it would appear that a lightning discharge phenomenon on Venus of the intensity of the terrestrial variety (or weaker) would have sufficient power to be the mechanism involved.

Interpretation of Ionospheric Measurements made during Solar Eclipses

Hunaerts and Nicolet[1] have pointed out that the interpretation of *E*-layer measurements made during solar eclipses is very sensitive to the value of the effective recombination coefficient ($\alpha \times 10^{-8}$ cm.^{3} s.$^{-1}$) in the range $\alpha = 1$–8. For the eclipse of February 25, 1952, at points in the belt of totality, a value of α near the lower end of this range implies, in general, that the west limb of the Sun must have been much brighter than the east limb, and also that there can have been no source of ionizing radiation outside the visible disk. Conversely, a higher value of α requires the existence, in the corona, of sources which remained unobscured during totality, and only a small difference between the brightness of the west and east limbs. At Khartoum, for example, the intensity of the coronal component (I_c) and the difference between the intensities of the sources near the west and east limbs ($I_w - I_e$), both expressed as a percentage of the total radiation, are given by $I_c = 12 - 18/\alpha$ and $I_w - I_e = 2 + 39/\alpha$. The arbitrary assumption that there was no coronal radiation thus leads to the result: $\alpha = 1{\cdot}5$.

Fortunately the interdependence of I and α suggests the possibility of using a method of finding α which makes no arbitrary assumptions about I. If ionospheric measurements are made during the same eclipse at two stations, it ought to be possible, in principle, to express the intensity of a given source in terms of two different functions of α; equating these functions would then allow α to be determined. This technique has proved to be practicable using data obtained at Khartoum and Ibadan in 1952; the resulting expressions for the intensity (per cent) of the west limb source are $I_k = 15 + 18/\alpha$ and $I_i = 29 + 2/\alpha$, and similar expressions have been derived for the uniform disk and east limb components. The solution of the equations for the three sources allows the values of α at the two stations to be determined simultaneously; it is found that the difference between them is not significant and that the most probable value is $\alpha = 1{\cdot}2$.

This low value for α and the implied absence of any coronal radiation are at variance with the conclusions reached by Hunaerts and Nicolet, who find that $\alpha = 4$ and that 15 per cent of the total radiation originates in the corona. A valuable check would be provided if similar determinations of α could be carried out using the measurements made in other parts of Africa during the 1952 eclipse, and a fuller account of the method used, including numerical data for Khartoum and Ibadan, will appear elsewhere[2].

Hunaerts and Nicolet have also referred to the observation that ionospheric measurements made during the 1954 eclipse imply equatorial brightening and polar darkening of the Sun's disk[3]. This conclusion is independent of the assumed value of α, a change in which leads only to a change in the relative brightness of the west and east limbs; the amount of polar darkening and the magnitude of the uniform disk component are very insensitive to changes in α. As the 1954 measurements were not made in the belt of totality, no information on the possible existence of coronal radiation can be given.

This work was carried out as part of the programme of the Radio Research Board, and this communication is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research.

Atomic Time and the Definition of the Second

THE experience gained[1] with the cæsium resonator has shown that it can be used for establishing a unit of time interval with great ease and accuracy, and it is now important to decide how this new facility can best be incorporated into the general framework of time measurements. It is necessary first to outline the present position with rather more practical detail than has been given in the recent correspondence in these columns[2,3].

The unit provided by the present time signals is based on the diurnal rotation of the Earth, the astronomical observations being corrected for known irregularities and also smoothed over long intervals by means of quartz clocks. It is known in Britain as the second of provisional uniform time and in America as that of U.T.2. Corrections to the signals are published by the observatories responsible for them after some delay, about six months in the case of the Royal Greenwich Observatory. These corrections are obtained from a statistical study of the observations and of clock performances and thus give the most probable value of the unit. It is important to realize that the corrected assessment of the unit involves certain assumptions being made about the behaviour of the clocks and of the Earth, but there is good evidence that it is in general uniform to ± 4 parts in 10^9 during a year.

It is internationally recommended[4] that, in view of the known variations, amounting to ± 4 parts in 10^8 during the last century, in the period of rotation of the Earth relative to other periodicities of the solar system, the second of ephemeris time should be used for precise work. This is based on the length of the tropical year[5], which is subject to a small secular change and is therefore referred to the particular epoch 1 900·0, the definition of the second being 1/31 556 925·975 of the tropical year for 1 900·0. The accuracy with which this new unit can be given is governed by the accuracy with which the current tropical year can be determined. This determination is made in practice from observations of the Moon, and W. Markowitz, using the dual-rate camera which he has recently developed[6], estimates the probable error to be ± 5 parts in 10^9 for measurements extending over one year[7]. To obtain the accuracy of ± 5 parts in 10^{10} (as an outside limit, not probable error), already being used in frequency measurements, the observations would thus have to be extended over more than ten years, and this long interval would have to be subdivided into equal seconds. It appears, therefore, that the second of ephemeris time can be made available with the required accuracy only by using an atomic standard for interpolation purposes.

The correlation of the two units is thus not easy and, moreover, there may be a gradual departure between the two as pointed out by Bullard[8]. There may be some point, therefore, in the suggestion made by Clemence[2] that they should be defined independently, and that a separate name should be given to the atomic unit; but it would almost certainly give rise to confusion, because the physicist who usually obtains his time from time signals would have to inquire into the precise nature of those signals. It is surely preferable for the responsible authorities to make available a single unit of time, as is strongly advocated by Pérard[3]. Pérard states that this unit should be defined in terms of the astronomical second, the frequency N of an atomic standard being given by the relationship:

$$Nt = \frac{\text{tropical year for } 1\ 900{\cdot}0}{31\ 556\ 925{\cdot}974\ 74}$$

The difficulty here is that, in spite of the number of figures with which the denominator apparently can be given, the tropical year is unlikely to be determined more closely than to ± 5 parts in 10^{10} in ten years, which means that the full accuracy of the atomic standard would remain latent for that time. Physicists and radio engineers would have no alternative but to adopt some value and use it as an independent atomic unit.

The following tentative proposals are put forward in an attempt to overcome this difficulty: to make the atomic standard immediately available but to preserve a single unit of time closely linked with, although not defined by, that given by astronomical observations.

(1) The provisional unit of time should be the time of 9 192 631 830 cycles of the cæsium $Fm,(4,0) \leftrightarrow (3,0)$ resonance at zero field, and named 1 provisional second. This is the frequency obtained[9] in terms of the provisional uniform second in June 1955, but it turns out to be very near the value expressed in the average provisional uniform second for the period June 1955–June 1956, and no alteration is therefore recommended.

(2) The joint work of the National Physical Laboratory and the U.S. Naval Observatory at present in progress should be continued to obtain the value of the cæsium frequency in terms of the second of ephemeris time for a period of, say, five years, when the precision should approach 1 part in 10^9. As the length of the tropical year is varying by 2 parts in 10^{10} per year[10], there is little point in relating the two units more closely than this. Indeed, it may be sufficient to accept the relationship with a lower accuracy which will be available in a shorter time.

(3) This new frequency should ultimately be adopted for the definition of the second. It is expected that the value will not differ by an amount which is significant for most purposes from the provisional value, as the difference between the units of provisional uniform time and of ephemeris time is believed to be small during the present period. A step adjustment could also be made to bring actual time (epoch) to the ephemeris time-scale.

For the purpose of the definition the frequency will be given to 1 part in 10^{10}, as it will certainly be possible in the near future to calibrate the working standards in terms of the resonance with that precision.

(4) The closest relationship should be maintained by the appropriate authorities between atomic time and astronomical time in order to determine any departure between the two systems and also to preserve the continuity of time determinations over long periods. Quartz clocks and astronomical observations would be used for integrating atomic time just as quartz clocks are now used to subdivide astronomical time.

(5) As other atomic standards come into use, their frequencies should be expressed in terms of the provisional second defined in (1), and, later, in terms of the second as defined in (3). The provisional second is already available through the *MSF* standard-frequency transmissions[11,12].

In making these proposals, the understandable reluctance to break with a practice as old as civilization is fully appreciated; but a consideration of the precision of measurement alone shows that the astronomical unit of time is no longer sufficiently accurate for modern measurements of frequency and time interval.

Terrestrial Heat-Flow in Hungary

Numerous borehole temperature measurements have been made in the Carpathian Basin during the past seven decades. It has been found that the value of the geothermal gradient lies between 40 and 70 deg. C./km. The causes of this high value have not yet been established, since the thermal conductivity of the rocks has not yet been measured.

In the Liassic coal basin of South Transdanubia at Zobák and Hosszuhetény, the sinking of four big shafts offered a favourable opportunity of determining terrestrial heat-flow The shafts have at present reached depths of 550 and 600 metres respectively, and have been sunk throughout in the same Liassic calcareous shale. In order to determine heat-flow, several measurements of the virgin rock temperature were taken in the course of sinking the shafts. The thermal conductivity of rock samples was measured by a method very similar to that of Benfield[1] and Bullard[2].

The heat flow was computed according to the following formula:

$$q = \frac{T_2 - T_1}{\sum_{i=1}^{n} \frac{\Delta h_i}{\lambda_i}}$$

where Δh_i is the thickness of stratum with thermal conductivity of λ_i. According to measurements taken in shafts at a distance of 90 metres, the mean value and probable error of the terrestrial heat-flow is:

$$10^6 q = 3 \cdot 035 \pm 0 \cdot 010 \text{ cal./cm.}^2 \text{ sec.}$$

Our measurements taken in shafts are more direct and reliable than those performed in boreholes, as the virgin rock temperature at the bottom of the shaft is affected by not more than 0·02 deg. C. by ventilation. In boreholes it is the temperature of the drilling fluid that is measured, and this differs, often considerably, from the virgin rock temperature.

It is believed that the present measurements are the first ever attempted in continental Europe[3], and that the high value obtained may be of interest for the geophysicist and geologist. This high value affects mining operations rather unfavourably. Since at a depth of 570 metres the virgin rock temperature is 36° C., it may be assumed to rise to 60° C. at 1,000 metres to which it is planned to sink the shafts. Such high temperatures will present special problems in mine ventilation.

A detailed account of this work will soon be published elsewhere.

Effect of Altitude on the Position of the Magnetic Pole

In the most recent analysis of the Earth's magnetic field (for the epoch 1942), Spencer Jones and Melotte[1] evaluated forty-eight coefficients in the spherical harmonic expansion of the magnetic potential. Using their values for a spheroidal Earth, the X (northerly) and Y (easterly) components of the Earth's magnetic field were calculated at heights of 100 km. and 250 km. above the Earth's surface for $\theta = 5°$, $10°$, $15°$, $20°$ and $25°$ and for $\varphi = 240°$, $250°$ and $260°$ E., where θ and φ are the co-latitude and longitude respectively. The heights 100 and 250 km. were chosen to correspond to the E- and F-layers of the ionosphere. For the purpose of comparison, X and Y were also evaluated at the Earth's surface and in every case the value of $H = (X^2 + Y^2)^{1/2}$ was computed.

In order to trace any movement of the magnetic pole with increasing height, the above calculations were repeated on a much finer grid in the vicinity of the pole. Thus X, Y and H were computed for values of $\cos \theta = 0{\cdot}958$, $0{\cdot}962$, $0{\cdot}966$, $0{\cdot}970$, $0{\cdot}974$ and $0{\cdot}978$, and $\varphi = 256°$, $257°$, $258°$, $259°$ and $260°$ E. The results were plotted graphically, and the position of the pole at different altitudes is given in Table 1.

Table 1

Height	$\cos \theta$	φ
Ground-level	0·970	258° E.
100 km.	0·972	258°
250 km.	0·975	258(½)°

The position of the pole at ground-level is thus 76° N., 258° E., that is, 102° W., which agrees with the position given by Spencer Jones and Melotte[1]. It may be noted that for a spherical Earth, instead of a spheroidal Earth, they obtained the position as 77° N., 103½° W. It should be remembered that this is the position for the epoch 1942. For the year 1956, the latitude must be increased by approximately one degree with no appreciable change in longitude.

Table 1 shows that there is a gradual shift in the position of the pole with increasing altitude, the relation between $\cos \theta$ and altitude being linear. At a height of 250 km. the pole has moved northwards one degree, there being no measurable change in longitude. This trend cannot continue far, since, with increasing altitude, the effects of the higher harmonics in the expansion of the magnetic potential become less and less important. If the trend did continue, the magnetic pole would be directly above the geographical pole at a height of 1,500 km. It has been shown, however, that for $\theta = 0°$ the horizontal field cannot vanish at any altitude.

An interesting feature of the calculations was that in certain cases the value of H increased with height, due mainly to an increase in the X-component. This is not likely to be significant, however, and most probably reflects small errors in the coefficients of the harmonic expansion. Although the increase could be accounted for by currents in the ionosphere, this explanation can scarcely be true, since it was assumed from the outset that there was no external component of the Earth's magnetic field.

Harmonics in a Multi-Story Structure

THE design of structures to withstand earthquakes is largely empirical. It is found, from experience, that, if the structure is designed to withstand a horizontal acceleration of one-tenth that of gravity, the building suffers no more than superficial damage even in a major earthquake. Spectra of earthquakes prepared by Housner[1] would appear to indicate that accelerations much greater than this design value are reached. If any tall building is postulated, the lack of a theoretical basis for the accepted design criterion causes considerable hesitation, particularly where one or more of the harmonic frequencies of the building may coincide with partial frequency components of the earthquake. This uncertainty is largely responsible for structure design in New Zealand, and in some American areas, being limited to a maximum height. (In New Zealand this maximum height is 100 ft.) Prof. L. Jacobsen and Robert S. Ayre[2] commented on a uniform building (mass and rigidity constant at each story): "Current design-rules give reasonable results for the fundamental mode shears only and the higher mode shears require considerable increases in the proportionality or percentage factor, especially in the upper part of the building".

The possibility of excitation in the higher modes either being serious in itself or adding to the fundamental excitation in such a way that inter-story shear may become excessive has been one of the major uncertainties in the subject. Recent work at the Dominion Physical Laboratory, where an electrical analogue of a ten-storied building has been built and excited by earthquake accelograms, has shown that excitation of the harmonics for the case of a uniform building may be ignored. However, if the building is designed to the current design code (inter-story stiffness proportional to total mass above the inter-story section), then the harmonics do have a small effect on the upper two storys. The effect is shown in Figs. 1, 2 and 3 in the form of spectra of one particular earthquake.

These spectra are a plot of the fundamental period of a uniform ten-story building against the maximum equivalent static acceleration producing the same stress which occurs during the passage of the particular earthquake. The single-story spectrum shows the major peak at 0·4 sec. period. Fig. 2 and 3,

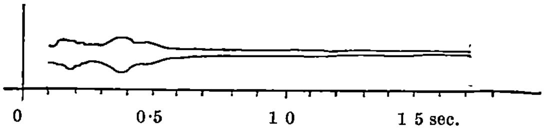

Fig. 1

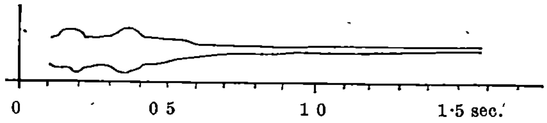

Fig. 2

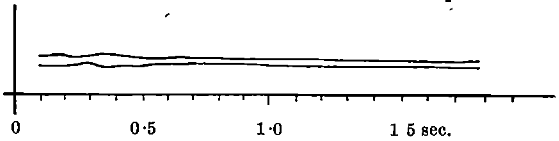

Fig. 3

Spectra for a uniform building: (1) single degree of freedom; (2) first story; (3) tenth story

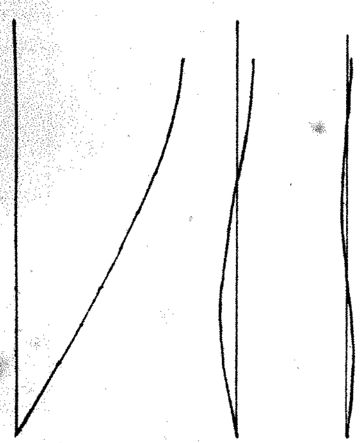

Fig. 4. Resonant amplitudes of the first three modes of oscillation for a fixed exciting acceleration

taken at the ground floor and top floor of a ten-story structure, show no peak at 1·2 sec., although the second harmonic of a structure of 1·2 sec. fundamental is 0·4 sec.

Fig. 4 shows the amplitudes developed throughout a ten-story structure when the ground undergoes a sinusoidal displacement at a constant value of peak acceleration and the frequency is made that of the various harmonics. The percentage damping is arranged to be the same for each mode.

It is concluded that, in a tall building, modes of oscillation other than the fundamental have far less effect than previously supposed. It is hoped that further work on the analogue machine may provide a theoretical basis for a more exact building code.

The work is to be published in detail elsewhere.

Mobility of π-Electrons in Heterogeneous Linear Molecules

THE observation that the lowest energy singlet transition in the electronic absorption spectrum of *trans*-chalcone (compound 8 in Table 1) had the same oscillator strength as that for *trans*-stilbene[1] led us to investigate other compounds of the type Ph—X and Ph—X—Ph, where —X— stands for a conjugated chain containing hetero groups such as —CO—, —N=N— and —CH : N.N : CH—.

In the majority of these compounds, a considerable part of the total absorption intensity is found in the lowest energy $\pi \rightarrow \pi^*$ transition, the oscillator strength ($f = 4{\cdot}32 \times 10^{-9}\int\varepsilon\, d\nu$) generally being measurable with accuracy, since the absorption band is well separated from the remainder of the spectrum[2].

Kuhn, in a semi-theoretical treatment of polyene chains as a system of coupled linear oscillators[3], concluded that the electrons were about 90 per cent mobile and that, among other things, the oscillator strength of the lowest singlet–singlet transition could be calculated from the equation

$$f = 0{\cdot}178n \qquad (1)$$

where n is the number of —CH : CH— groups in the chain. For the diphenyl-polyenes he calculated that a phenyl group was equivalent to 1·5 double bonds.

In particular, for *trans*-stilbene, our observed f-value for the $\pi \rightarrow \pi^*$ transition is 0·755 and $n = 4$, which leads to the empirical equation

$$f_{\text{obs.}} = 0{\cdot}189n \qquad (2)$$

If equation (2) is extended to include hetero compounds such as those in Table 1, it may be re-written more generally as

$$f_{\text{obs.}} = 0{\cdot}189(1{\cdot}5a + b + n_{\text{het.}}) \qquad (3)$$

where a is the number of phenyl and b the number of vinyl groups; in any molecule, n_{het}, the double-bond equivalent for each hetero group, may then readily be calculated.

The results are listed in Table 1. They show that the carbonyl group makes virtually no contribution to the $\pi \rightarrow \pi^*$ transition intensity; acetone itself exhibits very weak absorption in the near ultra-violet region of the spectrum (compound 2). The azo group also appears not to make an intensity contribution to the $\pi \rightarrow \pi^*$ transition in azobenzene, although it gives rise to a lower-energy weak $n \rightarrow \pi^*$ absorption. On the other hand, the alazine group (compounds 11 and 12) is equivalent to at least two double bonds, that is, to two conjugated vinyl groups.

The exception among the ketones is cinnamaldehyde, for the behaviour of which there is no obvious explanation on the basis of the present discussion, especially since benzaldehyde behaves in the same way as the remaining ketones. For di-cinnamalazine, and to a less extent for di-benzalazine,

* In water; all other spectra measured in 95 per cent ethanol. † Absorption still rising.

the situation is complicated by the fact that a further transition moderately intense in acetone-azine and possibly $n \rightarrow \pi^*$ in character, appears to have been shifted and intensified so as to overlap the strong absorption at low frequencies, giving apparently high values to n_{het}.

The conclusion from this work is that conjugated hetero groups in the chain of elongated planar molecules cause no decrease in mobility of the carbon π-electrons, even though such groups possess different types of orbitals from those in homogeneous conjugated molecules. This appears to be true whether or not the hetero groups themselves make a contribution to the intensity of the transition under consideration. Any such decrease in mobility would result not only in a marked decrease in intensity of the absorption band, but also in changes in its shape and location, with a consequent tendency for the band to overlap the remaining absorption at higher frequencies. On the contrary, a separate intense low-energy band is observed for the compounds containing one or two phenyl groups. These compounds must be in their fully extended 'all-*trans*' form, since it is well known that the corresponding stereoisomers containing one or more *cis*-bonds give rise to less intense absorption at the low-frequency end of their spectra[1,4].

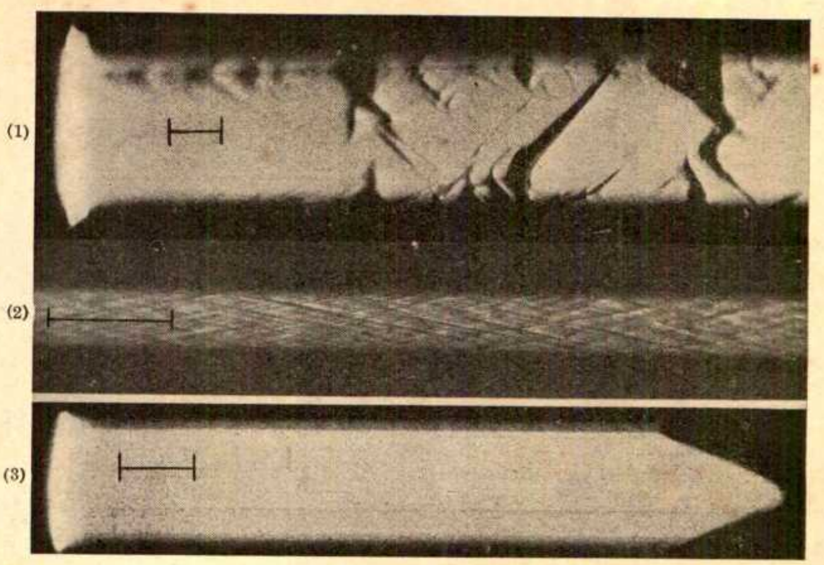

Fig. 1. End-on view. Dark-waves in nitromethane. Length of horizontal line corresponds to 1 microsecond

Fig. 2. End-on view. Dark-waves in nitromethane–acetone. Length of horizontal line corresponds to 1 microsecond

Fig. 3. End-on view. Nitromethane detonation running beyond foil lining and failing. Length of horizontal line corresponds to 1 microsecond

On the basis of the free-electron model, Bayliss has shown[5] that the intensity of the lowest-energy transition in a homogeneous conjugated polyene should be independent of its overall length and dependent only on the number of carbon π-orbitals. The present results indicate that this theory may be extended to include at least some types of conjugated heterogeneous molecules.

Detonation Phenomena in Homogeneous Explosives

We have observed in this laboratory that the manner in which a detonation proceeds in a homogeneous explosive is more complex than had previously been thought. Regions of relatively low luminosity have been observed in the detonation fronts of homogeneous solid and liquid explosives under certain conditions of diameter and confinement. Although these regions of low luminosity, which we call 'dark-waves', are larger and more numerous under conditions close to failure, they have also been observed under conditions in which the detonation is apparently proceeding at normal, constant velocity.

Fig. 1 shows the camera trace obtained with a rotating-mirror camera[1] looking end-on at a cylindrical tube of detonating nitromethane as the front advanced toward the camera. The nitromethane was confined in a glass tube, 0·642-in. internal diameter, and was at an initial temperature of 24° C. The rotating mirror was operating at 1,000 rev./sec., which corresponded to a writing speed of 1·8 mm./µsec. on the recording film. A 0·05-mm. slit was used in the camera. Fig. 1, then, is essentially a time-history of that portion of the detonation front seen by the fine slit as the front proceeded up the tube. The trace starts at the left with a band of high luminosity caused by the initiating explosive (composition *B*), and numerous dark-waves can be seen later in time as the detonation front approaches the region of good focus. The detonation continued for 6 in., which was the full length of the tube, in spite of the dark-waves.

Fig. 2 shows a similar trace obtained from a detonating mixture of 84 per cent nitromethane – 16 per cent acetone (percentage by volume) confined in a brass tube of 0·500-in. internal diameter. Initially, the liquid explosive was at a temperature of 23° C. The rotating mirror was operating here at 5,000 rev./sec., which corresponds to a writing speed of 9 mm./µsec., and a 0·2 mm. slit was used. The dark-waves seen in this weakened explosive are characteristically finer and more numerous. They appear to originate at the tube walls and to advance into the detonating liquid at a lateral velocity of about 4 mm./µsec. Again, this detonation is a stable one which will proceed indefinitely at a constant velocity.

Dark-waves have also been observed in detonating diethylene glycol dinitrate, ethyl nitrate, and single crystals of PETN. It is very likely that they are characteristic of finite-diameter, detonating, homogeneous explosives. They appear to be more prevalent at smaller diameters, weaker confinement and lower initial temperatures. The dark-waves can become so numerous and large as to cause abrupt failure of detonation. The evidence as a whole suggests that dark-waves are closely associated with hydrodynamic rarefactions originating at charge boundaries.

An interesting effect observed in connexion with dark-waves is that very thin metal foils can considerably reduce the diameter at which failure of detonation of nitromethane occurs and often completely prevent the occurrence of large dark-waves. Fig. 3 shows a camera trace obtained from a glass tube of less than failure-diameter, the first 2 in. of which have been lined with 0·002-in. stainless steel foil. The rotating mirror was operating at 1,000 rev./sec. and a 0·05-mm. slit was used. It can be seen that the detonation is propagated in the foil-lined region and then cut off sharply as it travels beyond the foil. Other experiments have shown that tungsten foil is more effective than steel, and steel is more effective than 'Dural' in reducing the failure diameter of nitromethane in glass. The denser foils are effective in thicknesses less than 0·001 in. The fact that these very thin foils can prevent dark-waves and failure suggests that either the reaction zone in nitromethane is extraordinarily thin or that the foils are effective in allowing the important first step of the reaction to start (and perhaps proceed for a short time) undisturbed by edge effects. Other experiments do, indeed, suggest that the detonation reaction in nitromethane proceeds in several distinct steps[2].

Further work is in progress on these subjects and we plan to publish additional details shortly. The work was done under the auspices of the U.S. Atomic Energy Commission.

The Cubic Form of Ice

Electron diffraction experiments have been carried out on deposits formed by water vapour on a base at low temperatures. The water vapour is produced in a separate injection unit outside the camera. The object of the experiments was to study, in particular, the diamond-type cubic form of ice observed by König[1] in deposits formed at low temperatures from the residual vapour in an electron-diffraction camera.

The cubic form was found by König to transform on heating into the normal hexagonal structure of ice at about − 80° C. These experiments were of the transmission type, which means that the ice layers can scarcely have been more than a few thousand angstroms in thickness. Experiments by Tschudin[2] on the free evaporation of massive ice in vacuum show, however, that at − 80° C. a layer of ice should be diminishing in thickness at a rate of at least three thousand angstroms a second. It would appear, therefore, that there is some form of contamination which effectively prevents evaporation. In view of the theoretical importance of a new form of ice at zero pressure, it was thought worth while to check the existence of this structure, using a method which allowed the supply of water vapour to be controlled. This was achieved by immersing the water in the injection unit in a bath, the temperature of which could be varied but was usually set at − 78° C.

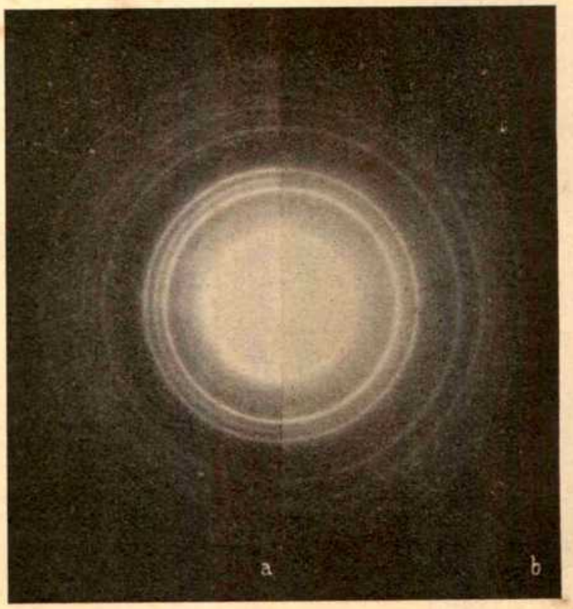

Fig. 1. Transmission patterns of ice: (*a*) hexagonal ice; (*b*) cubic ice

The deposits were formed on a base in a special low-temperature unit which fitted into an existing electron-diffraction apparatus. The unit is essentially a liquid-air jacket containing channels for the electron beam and for the water vapour from the injection unit. The specimen carrier is mounted on a brass disk which is connected both to a heater unit and to the liquid-air container. The temperature of the specimen can be varied from − 180° C. to room temperature.

Three types of diffraction patterns were found with the injection technique depending on the temperature of the base (see Table 1 and Fig. 1). The bases used in transmission experiments were: 'Formvar', collodion, silica, amorphous germanium. In reflexion experiments, cleaved galena was sometimes employed; the usual bases were, however, films of silver formed by evaporation on to heated mica. These have flat surfaces and give a diffraction pattern characteristic of a single crystal.

The same types of deposit were obtained as those found by König, though the characteristic temperature ranges are considerably different. This is in part due to the fact that the deposits in König's work were formed at very low temperatures and then heated. When similar experiments are carried out using the injection technique, the diffuse ring pattern changes on heating into the diamond-type cubic pattern at about − 115° C., the transition taking

Table 1. Injected Water Vapour

Temperature of base	Diffraction pattern	Comments
− 180° to − 140° C.	Diffuse rings	—
− 140° to − 120° C.	Sharp rings	Diamond-type cubic
> − 100° C.	Sharp rings	Hexagonal ice
> − 105° C.		Rapid evaporation

place in a temperature range of about 2 deg. C. The deposit evaporates completely at − 105° C. These results differ from those found by König in two respects. The transition point is substantially higher and better defined, and the layer evaporates completely at a much lower temperature.

To examine this point, deposits were formed from residual vapour in the camera, this being possible if the pumping period is not as prolonged as usual. When 'Formvar' or collodion was used as a base, results were obtained similar to those of König, including the transition from the cubic to the hexagonal form at − 80° C. With other bases, the layers evaporated completely at about − 105° C.; these bases were silica and amorphous germanium in the transmission work and silver in reflexion experiments. These and other experiments suggest strongly that the tenacious character of the deposits is associated with some contamination, which in its turn is associated with the organic bases.

The spacing of the cubic ice was measured at − 120° C., using thallium chloride and rocksalt as standards, the known spacings at room temperature being extrapolated to − 120° C., using expansion data at room temperature, Grüneisen's law and specific heat data.

The cube spacing of the diamond-type form of ice is found to be 6·351 ± 0·007 angstroms, at − 130° C., a value which is slightly lower than that found by König.

Experiments were also carried out using heavy water (of purity 99·72 per cent). The same three types of deposit were found as for ordinary water, the temperatures involved being only a few degrees higher than those characteristic of ordinary water.

The work described above has been made possible by grants from the Department of Scientific and Industrial Research and the Rockefeller Foundation. It is part of an interdepartmental programme organized by Dr. B. J. Mason, of the Meteorology Department of this College.

Symmetry of Azulene Crystals

The problem of the symmetry of azulene crystals was first put to me by Dr. H. H. Günthard[1] in 1949. He gave me some of the material from which I prepared, by sublimation, extremely pleochroic crystals.

The crystals showed the forms {001} and {110}, but in addition every crystal showed one, and only one, form of the plane (100). In other words, one acute corner of every diamond-shaped crystal was truncated. This seemed to me a strong indication that there was no axis of symmetry and that the space group was Pa and not $P2_1/a$. It is interesting to find from the communication of Prof. J. M. Robertson and Dr. H. M. M. Shearer[2] that X-ray statistical tests confirm the indications of classical crystallography.

Geometrical Isomerism of some Nitrophenylhydrazones of Benzoyl Formic Acid and their Infra-red Spectra

Recently, papers[1,2] have appeared describing *cis*- and *trans*-2 : 4-dinitrophenylhydrazones of some aliphatic α-keto acids. The structural assignment of the hydrazones as geometrical isomers was confirmed by means of infra-red spectra. Previously[3] we separated 2 : 4-dinitrophenylhydrazone of benzoyl formic acid into two forms, using a salting-out process, and found that the *trans*-form is changed into the *cis*-form by sunlight.

We have now investigated further this hydrazone, as well as mono nitrophenylhydrazones of the acid; it was found in each case that the *cis*-form sodium salt, from the isomeric mixture, could also be precipitated by salting-out with sodium carbonate. Each *cis*-isomer had a higher R_F value (on a silica gel chromato-strip[4] buffered by sodium phosphate), a longer $\lambda_{max.}$ and a lower melting point (except for the 2 : 4-compound). These constants and infrared data agree well with Isherwood's results[1] (Table 1). All these isomers were isomerized in carbonate solution, or by sunlight or heat.

Separation of the geometrical isomers. Well-powdered hydrazones (2 gm.) were suspended in about 80 ml. of $N/2$ carbonate solution, and various amounts of anhydrous sodium carbonate (0, 1·5, 3, 7 gm.) were then added for the 2 : 4-dinitro-, *o*-, *p*- and *m*-nitro compounds respectively. The precipitated salt (*cis*-form) was washed with carbonate solution. The filtrate was promptly precipitated with hydrochloric acid, and a pure *trans*-form was obtained by recrystallization from methanol with a small amount of acetone. To obtain a pure *cis*-form, the precipitated salt was dissolved in luke-warm water, and again precipitated by the addition of carbonate, and freed from sodium. Purification was by recrystallization from a mixture of methanol and benzene. The 2 : 4-dinitro compound was the most sharply separated. Solubilities of sodium salt of this *cis*-form (having 3·5 moles of water) in water and in normal sodium carbonate solution were 0·82 gm./l. and 0·01 gm./l., respectively. The isomer is sensitive to both light and heat.

Isomerization of the isomers. Isomerization was carried out in alcoholic aqueous solution, with or without addition of carbonate. Such solutions were either left in the sunlight or in the dark. Isomerization and decomposition were traced by studying, spectrophotometrically, the variations of $\lambda_{max.}$ and extinction. In carbonate solution, *m*-isomers were isomerized more distinctly, and accompanied by distinct decomposition. The transformation equilibria (starting from both forms) occurred at two different points according to whether the solutions were in the dark or in the light. This may indicate that isomerization occurs in ionic and in photochemical radical processes concurrently. Other isomers, however, isomerized rather slowly under the same conditions. Contrary to the *m*-isomer, the equilibria of the *o*- and *p*-isomers were at nearly the same respective points. The dinitro-compound, on the other hand, was completely converted into a *cis*-form, without decomposition. After exposure to sunlight, from a concentrated solution of the pure *trans*-form of this compound with carbonate, both forms were actually obtained almost quantitatively. Reverse isomerization could not be effected under alkaline or acidic conditions.

* In alcoholic aqueous solution. † s, strong ; m, medium ; w, weak.

Infra-red spectra of various phenylhydrazones of benzoyl formic acid and of mesoxalic acid. The infra-red spectra were all obtained with the substances in a paraffin mull. A Perkin–Elmer Model 21 spectrometer fitted with a rocksalt prism was used.

The spectra of all *trans*-forms of the four nitrophenylhydrazones of benzoyl formic acid were characterized by the appearance of weak and sharp absorption bands in the region 9·79–9·80μ. On the other hand, all *cis*-forms of these compounds showed medium bands in the 9·93–9·99μ region. With the phenylhydrazone (which is not separable into two forms), a band appeared in the same region as that of the *cis*-form. In the case of the 2 : 4-dinitrophenylhydrazones of mesoxalic acid, as well as of pyruvic acid (observed by T. Moriwaki[2]), there were no distinct bands in these regions.

In the case of the chelated *cis*-isomers, with the exception of the *m*-nitrophenylhydrazones, the strong carbonyl bands appeared in the longer wave-length region as with those of aliphatic acid derivatives, the original shorter wave-length bands of which almost disappeared. The obscure imino bands became more obscure (Table 1).

I am grateful to Profs. R. Nodzu and R. Gotō, of Kyoto University, for their helpful suggestions. The use of the Perkin–Elmer instrument was made possible through the courtesy of the Sumitomo Chemical Co., Ltd., in Osaka.

Formation of Free Radicals in Polymer Films on Irradiation

It is known that free radicals may be formed in rigid solvents[1–3], and that during the polymerization of acrylonitrile they may become trapped in the polymer[4]. The relative stability of the radicals under these conditions probably accounts for the instability of cellulose observed[5] after exposure to ultra-violet radiation. We have recently been studying the action of light on dyed and undyed films and some of our results are of interest in connexion with the recent observations of Ford[6]. In the course of our work, undyed films of cellulose acetate (deplasticized, British Celanese), nylon (no plasticizer, hexamethylene diamine – adipic acid, 0·004 in. thick, Du Pont de Nemours) and methylmethoxy nylon (no plasticizer, Imperial Chemical Industries) have been exposed to the effect of heat and/or radiation.

Our results with these films can be summarized briefly : (1) The absorption spectra of the unexposed films are not appreciably changed on heating in either oxygen or nitrogen in the dark at 50° C. for 150 hr. (2) After prolonged exposure in either gas to a high-pressure mercury-vapour lamp (G.E.C., Osram) only slight changes in absorption spectra are found either immediately after exposure or after storage in the dark at room temperature or at 50° C. (3) On exposure to a low-pressure mercury lamp emitting mainly at 2537 A., profound changes are produced in the films. These changes are (*a*) an effect shown immediately after exposure, and (*b*) a post-irradiation effect, which appears on storage in the dark and is greater on storage at higher temperatures.

The latter experiments were carried out in quartz absorption cells, and streams of dry nitrogen (oxygen-free) or oxygen were passed through them continuously throughout the experiment. Fig. 1 illustrates the changes with nylon film. After exposure for 20 hr. the peak in the unexposed film at 2800 A. is displaced to 2900 A. and is considerably increased. On heating in the dark at 50° C. for 300 hr. the peak reverts to about 2850 A. and is further augmented. This change occurs in both oxygen and nitrogen, and would seem to exclude the suggestion made by Ford[6] that the change in nylon films on irradiation is due to combination with oxygen. This may possibly occur to some extent during irradiation in oxygen ; but the similarity of the results in oxygen and nitrogen suggests that the full explanation is likely to be much more complex. Other workers[7,8] have observed the development of a band in the region of 2800–2900 A. on the heating of nylon at high temperatures in a vacuum, and it may be that the products formed on irradiation and on pyrolysis resemble one another.

After an exposure of 5 hr. it was observed that in nitrogen (but not in oxygen) the peak at 2800 A. in the unexposed nylon film was depressed and flattened immediately after irradiation, although after heating in the dark for 300 hr. at 50° C. the curves in both oxygen and nitrogen were beginning to show the trend displayed prominently in Fig. 1, that is, peaks in the region of 2850 A. It seems likely that the changes in absorption spectra are due to slow recombination of trapped free radicals formed by photolysis either with themselves or by a series of complex reactions with the polymer chain itself.

The results obtained with cellulose acetate film show one very interesting feature. Immediately after irradiation the increase in optical density of film exposed

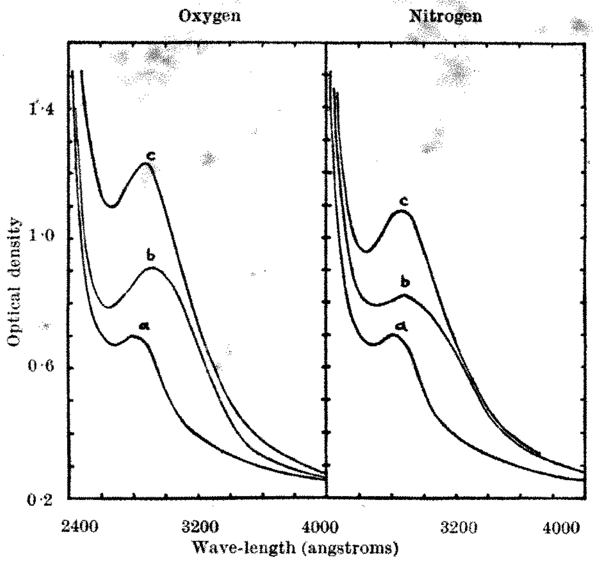

Fig. 1. Nylon film exposed to low-pressure mercury-vapour lamp: (*a*) unexposed; (*b*) immediately after 20 hr. exposure; (*c*) heated for 300 hr. at 50° C. after exposure

in dry nitrogen is greater than that exposed in oxygen, the difference apparently being greater the longer the period of exposure. It is thus not possible to ascribe such changes purely to reaction with oxygen. Methylmethoxy nylon films, which have no absorption peaks before exposure, are highly unstable to short-wave ultra-violet radiation. Although the changes are greater in oxygen than in nitrogen, there is some evidence in both gases of the formation of a peak around 2800 A., suggesting that the methylmethoxy group may possibly be split off the polymer chain on irradiation. Substantial changes occurred with these exposed films on heating at 50° C. for 300 hr.

There seems to be one important conclusion from this work which has a bearing on the related subject of the action of near ultra-violet and visible light, such as is present in sunlight, on textile materials. There is substantial evidence[9] that this phenomenon is completely different in mechanism from the photolytic effect of 2537 A. radiation. The results with the undyed films suggest that on irradiation with near ultra-violet and visible light no trapped free radicals are produced in the polymer material. It thus appears doubtful whether free radicals play any part in the degradation of textile materials which are exposed to sunlight behind glass.

A Complement-fixing Antigen from Egg-adapted Canine Distemper Virus

THE distemper complement fixation test, first used by Laidlaw and Dunkin[1] for measuring the antibody content of hyperimmune dog serum, has not been extensively employed in studies on this disease. These authors, together with Pyle and Brown[2], Mansi[3,4] and Hudson and Mansi[5], have all used relatively crude suspensions of infected dog tissue as antigen. The one attempt to demonstrate complement fixation antigen in various chick embryo tissues subsequent to infection with egg-adapted viruses was unsuccessful (Mansi[4]).

Preliminary experiments with the Onderstepoort egg-adapted distemper strain (190th chorioallantoic membrane passage) showed that virus-rich chorioallantoic membrane was able to fix complement in the presence of both distemper-immune and normal dog sera. This latter non-specific reaction was, however, greatly reduced following adsorption of the crude chorioallantoic membrane material with a strongly basic anion-exchange resin, 'Dowex-1'. A subsequent period of heating at 56° C. for 15 min. completely abolished non-specific activity without adversely affecting antigenicity. The procedure now to be described repeatedly yielded satisfactory complement fixation antigens.

Five days after inoculation of chorioallantoic membrane with a high concentration of seed-virus, grossly infected areas were removed and ground in a blender to form a 50 per cent (w/v) suspension in Kolmer saline (100 mgm. $MgCl_2.6H_2O$ in 0·85 per cent NaCl). The crude suspension was clarified by slow-speed centrifugation and then adsorbed for 30 min. at room temperature with an equal volume of 'Dowex 1*x*–10' resin (the adsorbant previously being converted to the sodium form with 10 per cent disodium hydrogen phosphate and repeatedly washed in distilled water). Following centrifugation, the supernatant fluid was removed and heated at 56° C. for 15 min. and finally titrated against immune dog serum by the 'chessboard' method to determine the optimal antigen concentration for routine use (usually a 1 : 2 or 1 : 4 dilution of stock material).

Antigens prepared by the above method were not anticomplementary, did not produce a precipitate when stored in the fluid state at 4° C., and when used with a 'short' fixation time (1 hr. at 37° C. prior to the addition of sensitized red cells) did not show the false positive reactions which often occurred following overnight ice-box fixation. Contrary to the observation of Mansi[4], it was found essential to inactivate at 56° C. for 30 min. all dog and ferret sera prior to testing, since unheated sera were invariably procomplementary and yielded false negative results. Using the above method, distemper-immune dog sera complement fixation titres of the order of 1 : 32 to 1 : 48 (50 per cent fixation end-point) were regularly obtained, while sera from young 'normal' puppies failed to react in a dilution of 1 : 5. It is of interest to record that these former sera when diluted 1 : 250 to 1 : 500 and mixed with approximately one hundred egg-infective doses of virus completely suppressed lesion formation on the chorioallantoic membrane. The negative sera in the lowest dilution tested (1 : 10) did not prevent virus growth.

Incidental observations made on the distemper antigen produced from chorioallantoic membrane suspensions showed the 'Dowex'-adsorbed material to be virtually inactive after heating for 30 min. at

56° C. Antigenicity was, however, completely retained at this temperature during the 15 min. necessary for the abolition of non-specific reactions with normal dog sera. Several unsuccessful attempts were made to prepare satisfactory antigens from crude chorio-allantoic membrane suspensions by precipitation either with methanol (30 per cent final concentration) or with protamine sulphate (0·5 per cent). These results will be reported on in detail at a later date.

Influence of Ionizing Radiation on the Appearance in the Serum of Rabbits of Humoral Factors slowing down Cell Division

WORK was undertaken to study certain physiological mechanisms which play a part in the reaction of higher organisms to ionizing radiations. I wish to record the finding in the serum of irradiated animals of a humoral factor that influences the rate of cell division. Experiments of a similar nature have been reported by other workers[1], who found, however, no or uncertain effects of humoral factors.

Rabbits received a single dose of whole-body X-irradiation of 900 r. (focal skin distance 90 cm., 190 kV., 12 m.amp., 0·5 mm. copper, dose-rate 20 r./min.). Blood was obtained by cardiac puncture 24 hr. after irradiation of the animals. Simultaneously and by the same procedure, blood was obtained from controls. Heart fibroblasts of chicken embryos were cultured quantitatively in roller tubes, using, with minor adjustments, the method described by Hull *et al.*[2]. 4 ml. of serum of irradiated rabbits or controls with the addition of 50–100 μc. of radiophosphorus as acid sodium phosphate dissolved in 0·1 ml. saline were used as culture medium. Growth, as indicated by the daily increment of the radioactivity of the culture, was determined daily for periods of about ten days; in later experiments, cultivation was discontinued after five daily measurements.

The reproducibility of growth-curves, as determined by the above-mentioned technique, was established in forty experiments, using identical serum in duplicate or triplicate cultures. The probable error in these experiments was about 10 per cent. The significance of the difference in growth-rate observed between tissue cultures grown on serum of irradiated rabbits and on serum of controls was tested by Fisher's *t*-test using the results of thirty-one experiments (fifteen irradiated, sixteen controls). The results show that tissue cultures grow more slowly on the sera of irradiated rabbits than on the sera of controls, the difference being about 30 per cent. This difference was statistically highly significant ($P < 0\cdot01$).

In further experiments, serum of irradiated or control sabbits respectively was added to the standard fluid medium and infected with a standardized suspension of *E. coli* (9 ml. standard medium + 3 ml. serum + 0·1 ml. standard suspension of *E. coli* in saline). Growth of the culture was evaluated by the turbidimetric method, using in early experiments a Coleman Junior spectrophotometer. Measurements were carried out at 650 mμ. In later experiments, the automatic recording photocolorimeter described by Marha and Jenšovský[3] was used.

To compare growth-rates, the values of $t_{1/4}$, $t_{1/2}$ and $t_{3/4}$ were determined. These values indicate the time necessary for the number of organisms, and so the turbidity of the culture, to reach one-quarter, one-half and three-quarters of the maximal value.

As in the case of our experiments with quantitative tissue cultures, the reproducibility of results using identical sera in duplicate or triplicate experiments served as a measure of the error of the method. A probable error of 2 per cent was obtained in our experiments, indicating that the method is well reproducible.

Table 1 shows the mean relative $t_{1/4}$, $t_{1/2}$ and $t_{3/4}$ for *E. coli* cultures using standard medium, standard medium with the addition of serum of controls and standard medium with the addition of serum of irradiated rabbits.

Table 1

Medium	Relative $t_{1/4}$	Relative $t_{1/2}$	Relative $t_{3/4}$
Standard medium	1·0	1·0	1·0
Standard medium + serum of controls	1·32	1·33	1·31
Standard medium + serum of irradiated rabbits	1·64	1·63	1·58

All the differences shown in Table 1 are statistically highly significant ($P < 0\cdot01$).

These experiments lead to the conclusion that the addition of rabbit serum to the standard medium decreases the growth-rate of *E. coli*. On addition of serum of irradiated rabbits, the growth-rate decreases still further. On analysing the growth curves, we find that the decreased growth-rates are caused by the prolongation of the initial stationary phase of the cultures.

In further experiments we have shown that when rabbit blood or rabbit serum is irradiated *in vitro*, it does not influence the growth-rate of *E. coli*, if added to standard culture medium. In order to produce this effect, the whole organism has to be irradiated.

In addition it was found that the factor responsible for hampering cell division is thermolabile, that it can be inactivated by heating to 56° C. for 30 min.; further, it was found that it does not pass through ultrafilters. On coagulation of the serum proteins at low temperature with an ether–alcohol mixture, the humoral factor stays in the coagulum. On dialysing the serum, the dialysate and the euglobulin fraction showed no influence on the growth-rate of *E. coli*. The pseudoglobulin and albumin fraction, however, prolonged the initial stationary phase of *E. coli*. On incubation of the serum for 1 hr. at 37° C. with *E. coli* killed by heating to 65° C. for 1 hr., the serum loses most of its depressing effect. Similar results are obtained on incubating the serum with a cellular suspension of calf thymus. Incubation of the serum with dead micrococci without toxic components typical of staphylococci, or with dead air-borne bacilli anthracoides, causes loss of ability of the serum to depress the growth of *E. coli*.

The experiments described prove, therefore, the existence of a humoral factor slowing down cell division on the serum of rabbits. The effect of this factor increases after irradiation of the rabbit. The fact that irradiation of blood or serum *in vitro* with doses of irradiation used in these experiments does not increase the ability of the serum to slow down growth of tissue cultures or *E. coli* indicates that this effect is not due to physico-chemical changes caused directly by the effect of ionizing radiation on the serum proteins, as assumed by Woenckhaus[4] and Žáček[5]. The whole organism must be irradiated to achieve this effect.

Probable Identity of an Antibiotic produced by a Spore-bearing Bacillus of the *B. pumilus* Group with Micrococcin

THE production of an antibiotic by a species of *Micrococcus*, isolated from Oxford sewage, was reported by Su[1], who named the substance micrococcin. Later, Heatley and Doery[2] gave an account of the preparation and some of the properties of purified micrococcin. They showed it to be relatively insoluble in water, to darken and sinter at 222–28° without having a sharp melting-point, to show a maximum in its ultra-violet light absorption spectrum in ethanol at 345 mμ (E 1%, 1 cm., 180), to have $[\alpha]^{21}_{D}$ + 116° (c, 5·0) in 90 per cent ethanol, molecular weight greater than 2,000, and to give the following elementary analysis: C, 49–49·5; H, 4·6; N, 13·9; S, 15·9 per cent. They also stated that "it gives a positive ninhydrin reaction only after acid hydrolysis, but this seems to be due to ammonia, not amino-acids. Nothing is known of its chemical nature". Still later, Fuller[3] isolated from cultures of a spore-bearing bacillus of the *B. pumilus* group, originating in soil collected in East Africa, an antibiotic, sparingly soluble in water, which became discoloured at 232°, sintered at 238°, and appeared to melt at 252°; it gave the following elementary analysis: C, 48·9; H, 4·7; N, 13·7; S, 16·0 per cent. It did not appear to give a ninhydrin test even after hydrolysis with hydrochloric acid and was thought to be of non-peptide nature.

The similarity in the properties of the antibiotics from these two widely divergent sources suggested that they might indeed be related in structure, and, in the interval, some progress[4] had been made with the study of the chemistry of the antibiotic obtained from *B. pumilus*, which had been found to have a maximum in its ultra-violet light absorption spectrum in 95 per cent ethanol at 345 mμ (E 1%, 1 cm., 210) and to have $[\alpha]^{21}_{D}$ + 63·7° (c, 1·19) in 90 per cent ethanol. On acid hydrolysis it broke down to give a series of compounds, conveniently considered in two groups, (i) soluble, and (ii) insoluble, in the cold diluted hydrolysis mixture. Continuous ether extraction of the acid-soluble fraction afforded a substance, $C_7H_7O_3NS$, and propionic acid, leaving still a complex mixture of substances, while treatment of the insoluble material with methanolic hydrogen chloride gave a non-basic substance, $C_{24}H_{23}O_5N_5S_4$, and a substance, $C_{16}H_{19}O_3N_3S_3$ (?), isolated as the picrate. Further examination of the water-soluble fraction left after removal of the substance $C_7H_7O_3NS$ showed it to contain ammonia in amount corresponding to about 23 per cent of the total nitrogen present in the antibiotic (micrococcin, 24·2 per cent[2]), and paper chromatography in butanol/acetic acid/water (63 : 10 : 27) revealed the presence of four ninhydrin-reacting substances giving spots of R_F about 0·20 (violet), 0·26 (yellow) forming a cap to another spot of R_F 0·32 (violet), and 0·52 (violet). Ion-exchange chromatography on 'Amberlite *IR*-120(H)' afforded the first and fourth of these ninhydrin-reacting substances in pure form. The slowest-running substance in the paper chromatography came off the resin first in N hydrochloric acid and proved to be L-threonine, while the fastest-moving substance in the paper chromatography left the resin last in 3 N hydrochloric acid and was a substance, $C_8H_{12}O_2N_2S$, isolated as the hydrochloride.

After acid hydrolysis of micrococcin, earlier carried out in Oxford, the same pattern of ninhydrin-reacting substances was shown on paper chromatography as that observed for the antibiotic from *B. pumilus*, and the two antibiotics have now been found to possess very similar infra-red absorption spectra and comparable fluorescence characteristics. In addition, redetermination of the optical rotatory power of micrococcin at lower concentration than that previously used[2] has given $[\alpha]^{21}_{D}$ + 62·2° (c, 1·10) in 90 per cent ethanol, and the substances $C_7H_7O_3NS$ and $C_{24}H_{23}O_5N_5S_4$ have now both been isolated after acid hydrolysis of micrococcin, so that a considerable degree of identity, or near-identity, between the antibiotics from the two sources has been demonstrated. However, with substances of such a degree of complexity as these one cannot be confident that they are identical in every detail, and it is still possible that, as in other cases among antibiotics, we have in these two substances two members of a group of closely related compounds. As the name 'micrococcin' is already established in the literature, it may be undesirable to apply a specific trivial name to the antibiotic produced by *B. pumilus* in view of the

Table 1

Test organism	Minimal inhibitory concentrations (μgm./ml.) in nutrient broth	
	Micrococcin	Micrococcin *P*
Bacillus cereus	0·05	0·05
Bacillus laterosporus	0·03	0·01
Bacillus firmus	0·4	0·4
Bacillus mycoides	0·02	0·02
Streptococcus haemolyticus, Group *C*	0·2	0·2
Streptococcus faecalis	0·05	0·05
Staphylococcus, Group *B*	0·07	0·07
Staphylococcus aureus "13"	2·0	2·0
,, ,, "21"	0·2	0·5
,, ,, "23"	0·5	1·0
,, ,, "24"	5·0	5·0
Leuconostoc citrovorum	0·02	0·01

The strains of *Staphylococcus aureus* had been isolated from hospital cases and were kindly provided by Dr. Mary Barber, Department of Bacteriology, St. Thomas's Hospital. Strains "13" and "21" were resistant to penicillin, streptomycin and oxytetracycline, while strain "23" was resistant to penicillin; strain "24" was sensitive to penicillin, streptomycin and oxytetracycline.

relationship between the two antibiotics that has emerged. On taxonomic grounds, however, the term 'micrococcin' is too narrowly suggestive of source to be satisfactory as a name for the antibiotic from *B. pumilus*; but, in the circumstances, it may serve as a chemically generic name, and we propose to refer to the antibiotic obtained from *B. pumilus* as 'micrococcin *P*', in the absence of evidence to show that the two substances are completely identical. As Table 1 shows, the antibacterial 'spectra' of the two substances were very similar, and organisms made resistant to one antibiotic were resistant to the other in comparable degree.

An account of the chemistry of micrococcin *P* will appear elsewhere[4].

Intra-cellular Identification of the Rous Virus

It has recently been established by an electron microscopical survey that the incidence of tumour cells with virus-like particles 70 mμ in diameter varied widely in the tumour-cell populations of different examples of Rous ascites tumours[1]. In view of the manifest impossibility of equating unknown particles with virus on morphological grounds alone, further experiments have been made in which morphological studies were combined with biological tests.

A sample of ascitic fluid was taken from each of five Rous ascites tumours and the number of tumour cells in it was determined using a hæmocytometer. Each sample was divided into two portions. The first portion was used to make electron microscope preparations by the method employed in the earlier work[2]. This method allows all the cells in a sample to be examined as well as the whole of each cell, and thus makes it possible to establish the incidence of tumour cells with particles in the total tumour-cell population. To do this, 3,000 cells from each tumour were searched in the electron microscope.

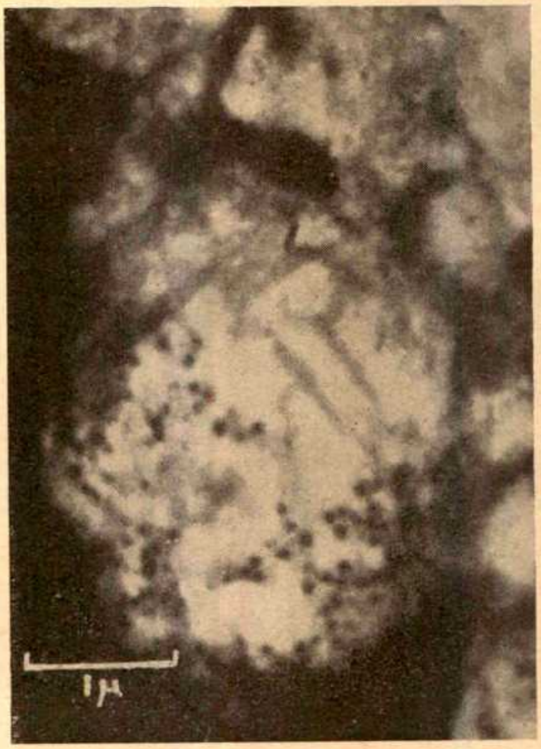

Fig. 1. Vacuole from a Rous ascites tumour cell showing a group of Rous virus particles; the limiting membrane of the vacuole can also be distinguished, particularly where it has become folded. Fixation over osmium oxide vapour was started after the cell had been *in vitro* for 21 min. and was continued for 30 hr. Electron micrograph, × 20,000

The cells in the second portion of each sample were collected by centrifugation, washed six times by centrifugation and then disrupted under standard conditions in a mechanically driven Ten Broek disintegrator. The virus released from the broken cells was titrated by diluting in serial tenfold steps and inoculating samples of each dilution intradermally in four young pullets. From the number of tumours which developed following the inoculations, that dilution of the virus suspension which would have caused tumours in 50 per cent of the birds was calculated[3]; the result has been expressed in terms of 1 ml. of ascitic fluid containing the cells from which the virus suspension was made and is shown in Table 1 as the 'tumour dilution 50 per cent' (*TD*50).

It can be seen from Table 1 that where few tumour cells with particles were found (Exp. 12) the tumour-producing activity of the virus extractable from the cells was low, while where many cells with particles were found (Exps. 10 and 11) this activity was high. The figures between these extremes (Exps. 9 and 13) also show close agreement. Statistically, the correlation is highly significant and $P = 0{\cdot}002$; taken in conjunction with the size of the particles and their appearance, this correlation makes it possible definitely to identify the particles as the Rous virus. From the results obtained it has also been possible to show that something of the order of 50 virus particles were the average minimum number needed

Table 1. CORRELATION BETWEEN INCIDENCE OF ROUS ASCITES TUMOUR CELLS WITH PARTICLES IN TOTAL TUMOUR-CELL POPULATION AND INFECTIVITY OF VIRUS EXTRACTABLE FROM THE CELLS

Exp. No.	Tumour cells per c.mm. ascitic fluid	No. of cells examined in electron microscope	No. of cells containing particles	Incidence of cells with particles	No. of cells with particles per ml. ascitic fluid	*TD*50 per ml. ascitic fluid
9	23,000	2,997	6	1/500	46,000	$10^{-5 \cdot 3}$
10	24,000	3,003	40	1/75	320,000	$10^{-6 \cdot 4}$
11	26,000	3,000	52	1/57	456,000	$10^{-6 \cdot 1}$
12	18,000	3,000	1	1/3,000	6,000	$10^{-4 \cdot 1}$
13	29,000	3,000	16	1/187	155,000	$10^{-5 \cdot 8}$

to cause a tumour under the experimental conditions used.

As in the earlier work[1], the virus particles have only been observed grouped together in association with the vacuoles which are commonly found in Rous ascites tumour cells. So far, 27,637 such cells, with their fine structure well preserved, have been examined in the electron microscope, and 168 of them have contained virus particles. In no single instance has the virus been observed lying free in the cytoplasm. The vacuoles have been found to have a limiting membrane; such a membrane can be seen around the vacuole shown in Fig. 1, particularly where it has become folded. A group of virus particles is also present.

A detailed account of this work is to be given elsewhere[4], together with a discussion of its significance and its relation to reports of unidentified particles in fowl cells, both from normal chick embryos[5] and from Rous tumours[6].

Effect on the Growth-rate of Weanling Rats of supplementing the Protein of White Bread with *l*-Lysine

WE have recently re-investigated the rates of growth of rats, of both sexes and at various ages, on diets in which all the protein was derived from white flour (70 per cent extraction) or from wholemeal. The stimulus for this re-examination was provided by the publication by Widdowson and McCance[1] of their results of the growth of both children and animals on diets containing a large proportion of wheaten flour. Our experiments have shown[2] that the superior growth-rate of male weanling rats on the protein of wholemeal, compared with that of white flour, is due to the higher lysine content of the wholemeal protein. This work also demonstrated the extreme sensitivity of the weanling rat to small changes in the lysine content of the diet, when wheaten flour is providing the protein. We have accordingly now investigated the growth response of male weanling rats when small increments of *l*-lysine were added to a diet in which the protein was provided by white bread. Similar experiments have been carried out by Rosenberg and Rohdenburg[3], Rosenberg, Rohdenburg and Baldini[4] in the United States; but the bread used contained 3 per cent non-fat milk solids.

This type of experiment was of additional interest since it is known that, with certain diets, an increase in the content of a single amino-acid may lead to a reduced rate of growth through inducing an amino-acid imbalance. This effect, and the related problem of antagonism between certain individual amino-acids, have been extensively investigated by Elvehjem and co-workers, and a paper[5] by the Wisconsin workers gives a comprehensive list of references to earlier work. The results we have obtained are given in Table 1.

Table 1. RESPONSE TO THE ADDITION OF *l*-LYSINE TO A DIET IN WHICH THE PROTEIN WAS SUPPLIED BY WHITE BREAD CRUMB
(Growth of male rats measured over 28 days from weaning)

Lysine addition (per cent)	Nitrogen in diet (per cent)	Mean weight gain per rat per day (with 95 per cent fiducial limits)	Mean food intake per rat per day (with 95 per cent fiducial limits)	Ratio of weight gain to intake of nitrogen
0·0	2·15	1·2 gm. ± 0·2	7·4 gm. ± 0·5	7·8
0·06	2·16	1·9 gm. ± 0·2	9·1 gm. ± 0·5	9·5
0·12	2·17	2·3 gm. ± 0·2	9·2 gm. ± 0·5	11·4
0·18	2·19	3·0 gm. ± 0·2	11·0 gm. ± 0·5	12·4
0·24	2·20	3·4 gm. ± 0·2	11·3 gm. ± 0·5	13·7
0·30	2·20	3·3 gm. ± 0·2	11·1 gm. ± 0·5	13·6

The diet was adequately supplemented with vitamins and minerals. It contained 80 per cent by weight of white bread, 5 per cent arachis oil and the balance sucrose.

From Table 1 it will be noted that the optimum response was provided by the addition of about 0·25 per cent *l*-lysine. The lysine content of the unsupplemented diet measured by the Moore and Stein technique[6], using the ion-exchange resin, 'Zeocarb 225', was 0·25 per cent. Thus the best growth-rate was obtained at a lysine content of about 0·5 per cent.

An earlier experiment, with five lysine supplements increasing from 0·2 per cent, by increments of 0·1 per cent to 0·6 per cent, had also shown that the optimum response in growth-rate (again 3·4 gm./rat/day) was reached with a lysine addition between 0·2 and 0·3 per cent. There was an indication of a slight fall (only just significant at $p = 5$ per cent), in food consumption and in gain in weight, with the lysine addition of 0·6 per cent. It was therefore of interest to ascertain whether the addition of a still greater quantity of lysine would depress the growth-rate by inducing an amino-acid imbalance. To test this point the growth-rate with an addition of 0·3 per cent lysine (a level where the plateau for growth-rate had been reached) was compared with that when the supplement was 1·2 per cent lysine. In the first week of this experiment the growth-rate was significantly less at the higher lysine-level (2·8 gm./day as against 3·6 gm./day at the 0·3 per cent lysine-level). But the food consumption was also less. During the following two weeks the difference in rate of gain in weight narrowed, and the results for growth over 21 days are given in Table 2.

At the higher lysine-level the rate of gain was less, but so also was the food intake. The use of a highly significant ($p \sim 0·1$ per cent) linear regression of weight-gain on food-intake indicates that the reduced rate of gain may be wholly accounted for by the reduced food consumption.

One of the most interesting features of these observations is the good rate of growth (3·4–3·6 gm. per rat per day) which is obtained when wheat protein is supplemented by a small addition of lysine.

Table 2

Lysine addition (per cent)	Nitrogen in diet (per cent)	Mean weight gain per rat per day	Mean food intake per rat per day	Ratio of weight gain to intake of nitrogen
0·3	2·36	3·6 gm. ± 0·3	11·2 gm. ± 0·5	13·7
1·2	2·54	3·2 gm. ± 0·3	10·2 gm. ± 0·5	12·5

In this experiment white bread crumb provided 90 per cent by weight of the diet.

The growth-rate is almost trebled compared with that obtained in the unsupplemented bread ; an observation which is closely similar to those made by Rosenberg, Rohdenburg and Baldini[4]. It should be emphasized that our observations have only been concerned with growth, and the effect on other aspects of development needs to be investigated.

Anticoagulant Action of Neodymium 3-Sulpho-*iso*nicotinate

ALTHOUGH it has long been known that the rare-earth metals interfere with blood clotting both *in vitro* and *in vivo*, it was not until 1950 that Vincke and Sucker[1] described, in neodymium 3-sulpho-*iso*nicotinate, a compound that was sufficiently soluble and free of toxic effects for clinical use. It is given by intravenous injection in 2·5 per cent solution and was at first regarded as a prothrombinopenic agent on the basis of a prolonged one-stage 'prothrombin' time. Recently, using newer techniques, Beller and Mammen[2] have reported that neodymium acts by reducing factor VII and factor X, leaving prothrombin normal. We have meantime been studying, independently, the mode of action of this salt, using in particular the blood thromboplastin generation test[3], with the following results.

In intravenous doses of the order of 5 mgm./kgm. in man and rabbits, it led to impairment of intrinsic blood thromboplastin generation by inhibiting, in the circulating blood, two thromboplastin constituents normally present in serum, namely, Christmas factor (*PTC*, factor IX) and factor X[4,5]—and also to reduction in factor VII (*SPCA*, stable factor) activity. It is this action on factor VII (which, it is now recognized, plays no part in blood thromboplastin formation) that is responsible for the prolonged one-stage 'prothrombin' time. These effects were demonstrable in four hours and lasted for twenty-four hours or slightly longer. With this dosage there was no alteration in the antihæmophilic globulin activity of the plasma, and the whole-blood clotting time in glass remained normal. With larger doses of 50 mgm./kgm. in animals, however, in addition to the above effects, the whole-blood clotting time was greatly prolonged and the activity of antihæmophilic globulin was reduced. In neither case was there any interference with prothrombin measured by the two-stage method, or with the thrombin–fibrinogen reaction. The action on factor VII and the serum thromboplastin factors was not prevented by oral premedication in humans with vitamin K_1 in 50-mgm. doses. In fifty-four injections in twenty patients no toxic effects were encountered.

Bergsagel[6] has shown that calcium interacts with Christmas factor at an early stage in the formation of blood thromboplastin. Since calcium and neodymium are similar in their chemical properties but are not, of course, biologically interchangeable, it is possible that neodymium acts as an antimetabolite of calcium by displacing it from combination with one or more of the protein factors in coagulation, although to date we have no evidence that excess of calcium will prevent the action of neodymium *in vitro*.

Trans-Synaptic Atrophy in the Cerebral Cortex

THE disappearance of neurones from the primate lateral geniculate body after de-afferentation has been clearly demonstrated[1], and less dramatic trans-synaptic degenerative changes have been described elsewhere in the central nervous system, for example, in the cortex of the piriform lobe after degeneration of the olfactory tract[2]. Hitherto, however, attention has been focused on the perikaryon, and the role of afferent input in preserving the normal dendritic organization of neurones has apparently never been studied.

We have examined the pyramidal cells in the pre-piriform cortex of the rat after removal of the olfactory bulb, which is known to be the main source of afferent fibres to this region[3]. Comparison of the two sides of rat brains subjected to unilateral olfactory bulb resection has revealed no obvious differences in the nuclei or perikarya of the pyramidal cells, apart from a slight reduction in size, in material stained with buffered thionin, or in the fibre plexuses in material prepared by the Holmes–Silver impregnation technique. In Golgi–Cox preparations, however, a marked reduction in the number of dendritic branches arising from the pyramidal cells on the operated side has been consistently observed during the examination of a large number of neurones in three brains.

This change is very conspicuous a hundred days after operation on forty-day old rats. It is readily observed in the plexiform layer, the second of the five layers into which the pre-piriform cortex has been subdivided[4]. This layer contains the dendrites of the pyramidal cells as they pass to synapse with the axons of the lateral olfactory tract, which spread out over the surface of the piriform lobe. Typical examples of normal and atrophic pyramidal cells that appeared to be completely stained are shown in Fig. 1 ; their silhouettes were traced under the micro-projector. We conclude that the normal pattern of dendritic organization of the pyramidal cells in the pre-piriform cortex is dependent upon the integrity of their afferent input.

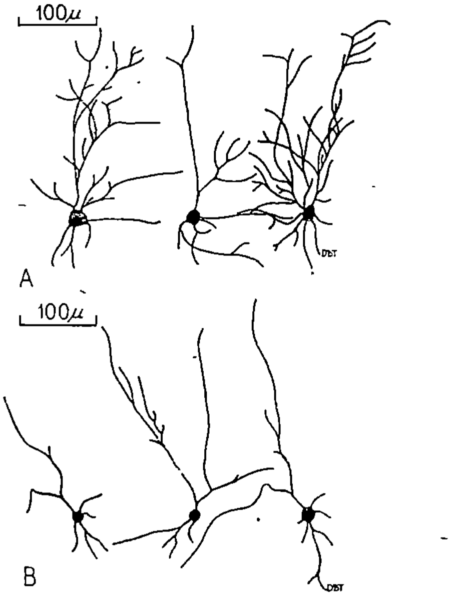

Fig. 1. Pyramidal cell bodies in the pre-piriform cortex of a rat killed a hundred days after unilateral olfactory bulb resection at the age of forty days: *A*, normal side; *B*, side of operation (Golgi–Cox preparation, micro-projector tracing)

Further work is in progress and will be reported elsewhere. We are indebted to Prof. J. Z. Young, who placed the facilities for this investigation at our disposal, for his advice and encouragement.

The Longevity Function: Some Additional Data from Domestic Animals

In 1825, Benjamin Gompertz[1] analysed the function expressing the law of human mortality and suggested that the rate of mortality increased in a logarithmic manner with the age of the population. Recently, Kershaw, Chalmers and Lavoipierre[2], analysing the pattern of mosquito survival in laboratory conditions, showed that, for a cohort of 1,200, the Gompertz function was linear for both male and female.

Unfortunately, only figures of percentage survival were available for this cohort, and it was desirable to check the function by constructing a life-table. An appeal was therefore made for information on other survival data, published or unpublished, and information was obtained by one of us (J. O. L. K.) on cohorts of 167 draught horses, 63 breeding sows, and on 79 Ayrshire and 82 British Friesian cows. The criterion in these cohorts was economic—the working-life of the horse, the breeding-life of the sow and the milking-life of the cow.

The cohorts, when analysed by the graphic method introduced by Kershaw *et al.*, for numbers near or less than 100, yield a linear Gompertz function. The data on the horses and on the sows, when plotted as a frequency distribution curve of the number of animals against the economic life, show a normal probability curve, and similar curves for each herd of cows show a log-normal distribution.

We have analysed all the data available to us, including information published by the United States Atomic Energy Commission[3], on the survival of mice, guinea pigs and rabbits (the results will shortly be published in detail in the *Annals of Tropical Medicine and Parasitology*); but we have so far been unable to determine why some distributions are normal whereas others are log-normal; nor have we been able to correlate the type of curve with any feature of the biological system involved or with the criterion of survival.

It would appear that the determination of the pattern of mortality of biological systems is of such fundamental importance that all available information should be analysed; we therefore reiterate our appeal for information on survival data.

Relation between Genetic Constitution of an Offspring and Weight of its Litter-mates

Rabbit does, drawn from a single stock, were artificially inseminated, either from one large buck of the same stock or from one small one of a different strain[1]. The two types of offspring were distinguishable by pre-arranged genetic factors. Offspring of the large buck averaged 2·7 gm. heavier at birth than offspring of the small buck. When they were raised in the same litters, after heterospermic insemination with mixed semen, the difference in birth-weight increased to 6·1 gm. The increase may be called the 'enhancement effect' in relative birth-weight.

This result prompted investigation of a naturally occurring analogue of the experiment. In mammalian dizygotic twin births, there are again two recognizable types of offspring, male and female, whose genetic constitutions carry with them a weight difference, the males being the heavier in most species. Also, the two types of offspring are born either in litters of one type (like-sexed twins), or are born together in the same litters (unlike-sexed twins). Is the difference in birth-weight of the sexes greater in unlike-sexed twins? As shown in Table 1, there is, in fact, an apparent enhancement effect in six sets of data for sheep twins. In the first two sets of data[2], which are unweighted averages, the effect was not found statistically significant by the authors. The small third group, a combination of the control data of three experiments[3-5], also shows an enhancement effect, though not significantly. This group was obtained by listing the four series of births that

contained figures for all four types of offspring; birth-weights were then averaged successively within and between series. The material on the Langhe sheep was calculated from the original record abstracts of Mason and Dassat[6]; birth-weights of the four types of offspring were averaged first within and then between the nine flocks for which complete data were available. Again, an enhancement effect resulted. A fifth and sixth set of unweighted data, each showing an enhancement effect, were calculated from the records of the Trawscoed Experimental Farm. Finally, an enhancement effect is apparent in human twins[7]. In all these comparisons, a small incidence of identical twins might affect relative numbers in the classes of offspring, but would not be expected to bias the average weights.

Individually, the sources of information may not show a statistically significant enhancement effect. But it is rather striking that the effect should be apparent in eight successive sets of data (one for rabbit, six for sheep, one for man). A *t* test indicated that the chance of such a regularity being due merely to sampling error was less than the conventional significance limit of one in twenty. It may also be calculated that the unweighted mean of the last column in Table 1 (+ 0·44) is significant in comparison with its standard error (± 0·152).

These eight sets of data all point towards the same conclusion; when genetically large and small offspring are born together in mixed litters, their difference in weight at birth is greater than when the offspring are born in litters of one type only. This may be ascribed provisionally to embryonic competition, in the sense that the large offspring grows unduly large at the expense of the small offspring. As may be seen in Table 1, increased weight of the male offspring contributes fairly regularly to the enhancement effect; but until more data are available, it cannot be said how regular is the contribution of decreased weight of the female offspring.

In the literature of mammalian genetics and animal breeding, there seems to be little or no recognition of an enhancement effect. If it should prove to be of general occurrence, it could have significance in several contexts. For example, in the rabbit experiment mentioned above, the estimate of superiority of one sire over another, in terms of birth-weight of offspring, varied according to the method of progeny testing; insemination with mixed semen gave a greater superiority than that obtained after the more usual type of progeny-testing with semen from one sire at a time. Enhancement is a relative term, and it might equally well be said that ordinary progeny-testing has a minimizing effect. Which test gives the correct measure of genetic superiority between the two males?

A wider possibility for multiple births in general, and not only twins, is that an enhancement effect may occur when one embryo of a litter becomes larger than a litter-mate for any reason, not necessarily genetical; for example, owing to some local uterine condition. Something like an autocatalytic process may occur; once an embryo has become large, it may have a competitive advantage and become unduly large while growth of the smaller one will be retarded. Thus, differences in weight between embryos would become exaggerated during gestation. Studies of the origin of variation in birth-weight within the mammalian litter are liable to be biased unless this source of variation is taken into account. Moreover, further evidence from the rabbit experiment suggests that the enhancement effect measured at birth is still evident after weaning.

This work, which will be published in full, was carried out with financial support from the Agricultural Research Council. I am indebted to Prof. C. H. Waddington for interest and facilities. For access to records, I am indebted to I. L. Mason and P. Dassat, and to the Director and Staff of the National Agricultural Advisory Service Experimental Husbandry Farm, Trawscoed, Aberystwyth.

Dominance Order for Red–Green Defective Alleles

On the theory of Franceschetti[1,2] there are two series of multiple alleles for defective colour vision, one series responsible for deuteranopia (*D*), extreme deuteranomaly (*EDA*) and deuteranomaly (*DA*), and the other for protanopia (*P*), extreme protanomaly (*EPA*) and protanomaly (*PA*). His theory suggests that there is a dominance order for each series, such that the genes producing the lesser defects are dominant to those producing the greater, and that the two normal genes are most dominant.

This theory is supported by many pedigrees[3-7]; but it is possible to test it statistically by comparing the frequencies of defective men with those of defective women. On the theory, since the less defective genes are more dominant, and defective women are those who carry two defective genes, there should be more of the lesser defective women in proportion than of the lesser defective men.

In a group of 126 red-green defective men and women, all tested with the Rayleigh equation, in one or other form of anomaloscope test, the following frequencies were found.

	PA	*EPA*	*P*	Total
Men	15	28	20	63
Women	4	4	2	10
	DA	*EDA*	*D*	Total
Men	53	66	12	131
Women	15	7	0	22

Some of these subjects were included by chance, and others were invited as being suspected defectives, because they had made errors in daily life, or on the Ishihara or lantern tests. Since there was a special interest in defective women, more in proportion of these were invited, and there are probably three times as many as would be expected if all subjects had been found purely by chance. The fact that some subjects were invited does not affect the relative frequencies of the different types. The subjects were sometimes related; but this was not more frequent in one group than another, and does not affect relative frequencies.

Owing to the small frequencies in some of the cells it is convenient to combine the protan and deutan groups, and it is necessary to use Yates's correction. Chi-squared for the resulting table, in which we compare the relative frequencies of women with men defectives, is 9·70, and is significant on the less than 0·01 level for two degrees of freedom. It is to be inferred that there are relatively fewer *P* and *D* women than men, relatively fewer *EPA* and *EDA* and more *PA* and *DA*, as predicted by the theory being tested, which is therefore supported by the data.

Photoperiodic Promotion of Vegetative Growth in the Cultivated Strawberry Plant

The strawberry variety Royal Sovereign is a short-day plant, flower initiation being promoted by short photoperiods, whereas stolon formation and increased petiole length are promoted by long photoperiods[1]. Hartmann[2] has shown that in short photoperiods parent plants of the variety Missionary are able to induce flower formation in attached runner plants growing in long photoperiods. This he interpreted as evidence of the transmission of a hypothetical flower-forming substance along the stolon in an acropetal direction.

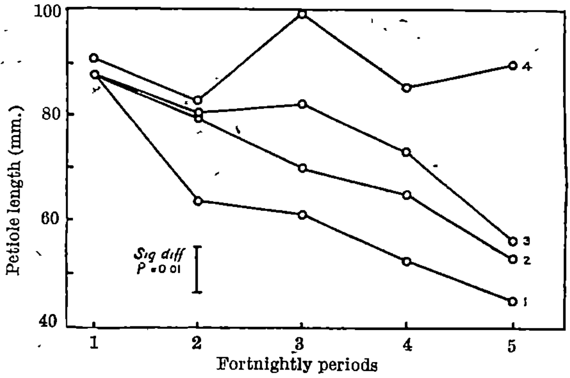

Fig. 1. Mean petiole lengths (mm.) of leaves emerging from the bud during five successive fortnightly periods

Evidence is now presented for the transmission in the opposite direction along the stolon of a substance or substances promoting stolon formation, increased petiole-length, and antagonizing the processes leading to flower formation.

Pairs of runner plants of the variety Royal Sovereign were rooted singly in pots in the field in summer. Each pair consisted of adjacent plants in a runner train. On August 11 the pairs were lifted in their pots, and the stolon, joining members of a pair, was retained intact. From this date the older of each pair of plants, described as the 'parent' plant, was grown under a 9-hr. photoperiod in the glasshouse. The attached runner plant received continuous illumination by supplementing natural light with light from incandescent lamps, initially at 15–20 ft. candles, but later increased to 30–35 ft. candles. Four defoliation treatments, with four-fold replication, were imposed. Treatments consisted of the removal of (1) all leaves, (2) all but the youngest fully expanded leaf, and (3) all but the youngest two fully expanded leaves from the runner plants. Unfolding leaves were retained in all except treatment 1. Plants of treatment 4 were not defoliated. The leaf status in treatments 1–3 was maintained by weekly removal of the oldest leaf where necessary, so that plants of treatments 1, 2 and 3 had 0–1, 1–2 and 2–3 fully expanded leaves respectively during the experiment. Parent plants were left intact. Control pairs, two in each defoliation treatment, were grown with both parent and runner plants in continuous light.

After prolonged treatment two of the four runner plants of treatment 1 (all leaves removed) initiated

Table 1. RESPONSE OF PARENT PLANT TO LONG-DAY TREATMENT OF ATTACHED-RUNNER PLANTS

* Assuming six developing leaves in the bud.
† One plant had not initiated an inflorescence by the time the experiment was terminated. Figures in brackets are $\sqrt{n + \frac{1}{2}}$ transformations.

inflorescences, after initiating a mean number of 11·0 leaves. This alone is in support of Hartmann's experimental results with the variety Missionary. No other runner plants produced inflorescences.

The purpose of this communication is to direct attention to the results given in Table 1 and Fig. 1. The presence of leaves on runner plants in continuous light was associated with delayed inflorescence initiation, increased stolon production and increased petiole length in the parent plants growing in short photoperiods. Moreover, the effect was proportional to the number of leaves retained on the runner plants. All these responses are characteristic of the effect of long photoperiods on the strawberry.

It is suggested that the runner plants acted as donors and the parent plants as receptors of a quantitatively active stimulus promoting vegetative as opposed to reproductive growth.

The experiment was designed as a preliminary study of the influence of leaves on the runner plant in long photoperiods upon the response of the runner plant to a flower-inducing stimulus received via the stolon from the parent plant. The control layout, while adequate for the original purpose, does not preclude an explanation in terms of nutritional factors. However, the appearance of the critical parent plants, which made vigorous growth, typical of short-day responses in the variety, suggests that formative rather than nutritional factors were operating.

Further work is in progress.

Seed Vernalization and Flowering in Lettuce (*Lactuca sativa*)

Temperature, photoperiod, and chemical regulators, separately and interacting, markedly influence seed-stalk development in lettuce[1]. Conflicting reports have, however, appeared as to the effectiveness of seed vernalization in accelerating flowering in this crop[2]. In order to resolve these differences, leaf number preceding the visible inflorescence has been used as a 'physiological index' of flowering[3], and the effects of seed vernalization, in combination with temperature, day-length, and chemical regulators, have been evaluated.

A standard procedure was used for the vernalization of head lettuce seed (*Lactuca sativa*, variety Great Lakes), consisting of pre-germinating moist seed at 60–70° F. for 24–48 hr. and then subjecting to 40° F. for at least thirteen days. Periodical temperature interruptions of 60–90° F. for 2 hr. daily, or at three-day intervals, did not nullify the vernalizing effect of cold exposure. Seed which was pre-germinated for three days or more at 60° F. was not effectively vernalized by subsequent exposure to 40° F. Plants from lettuce seed which had been soaked at 60–70° F. and air-dried 6–12 hr. prior to chilling at 32° or 40° F. were delayed in flowering as compared with those vernalized according to the standard procedure. When maleic hydrazide (20 and 40 p.p.m.) was added to the water which was used in moistening the seed during vernalization, plants afterwards produced visible flower parts at a lower node than did plants from seed vernalized in water alone. (The maleic hydrazide was formulated as the water-soluble diethanolamine salt of 1,2-dihydro-3,6-pyridazinedione and applied as 'MH-40' by the U.S. Rubber Company, Naugatuck Division, Naugatuck, Conn.)

When lettuce plants were grown at night temperatures above 65° F. subsequent to seed vernalization, seed-stalk development was accelerated without preceding head formation. At temperatures below 65° F., plants grown from vernalized seed first produced a high percentage of firm, vegetative heads and then flowered. Non-vernalized plants flowered only at night temperatures above 65° F. The potential for flowering was decidedly greater following seed vernalization, but flowering was afterwards delayed by continuous night temperatures below 65° F. and was completely absent at 50° F. Much of the disparity in results obtained with seed vernalization of lettuce by various workers may be resolved on this basis.

Soil temperatures influenced the rate of seed-stalk development (days to anthesis), but not the vernalization stimulus *per se* (leaf numbers preceding the inflorescence). At the higher soil temperatures (64° and 70° F.) flowering was promoted, whereas at lower temperatures (50° and 57° F.) flowering was delayed. A decrease in the percentage of plants which produced seed-stalks occurred as soil temperatures declined from 71° to 50° F.

Likewise, photoperiod markedly affected flowering of vernalized head lettuce. The minimum night temperature following vernalization which favoured earlier flowering was reduced from 65° to 60° F. when plants were grown at a day-length of 16 hr. At 60° F. with a nine-hour day, both vernalized and non-vernalized plants formed firm vegetative heads which flowered simultaneously. Thus the flower-promoting effects of seed vernalization in lettuce may be nullified by short photoperiods as well as cool growing temperatures.

The delaying effect of cool (below 65° C.) temperatures (both soil and air) combined with relatively short days on seed-stalk development in greenhouse studies was verified in the field. Plants grown in the early spring, when night temperatures were less than 60° F., formed heads and remained vegetative irrespective of prior seed vernalization or treatment with chemical growth regulators.

This communication is based on a thesis submitted by one of us (L. R.) in partial fulfilment of the requirements for the Ph.D., Michigan State University.

FORTHCOMING EVENTS

Monday, July 9—Saturday, July 14

Society of Chemical Industry (at the Imperial Institute, Exhibition Road, London, S.W.7)—75th Annual Meeting.

Thursday, July 12—Saturday, July 14

Institute of Physics, Non-Destructive Testing Group (at the H. H. Wills Physical Laboratory, Bristol)—Meeting on "Physics of Some New Aspects of Non-Destructive Testing".

Friday, July 13

Biochemical Society (in the Department of Biochemistry, The University, Leeds), at 11 a.m —Symposium on "Metals and Enzyme Activity".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer, Grade B (graduate, preferably with teaching experience), in the Mathematics Department—The Registrar, Technical College, Sunderland (July 13).

Lecturer or Assistant Lecturer (with qualifications in physical or inorganic chemistry, and preferably with experience in radiochemistry) in Chemistry—The Registrar, The University, Hull (July 16).

Lecturer (preferably with special interests in entomology, physiology or protozoology) in Zoology at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 16).

Research Assistant (honours graduate in botany) at the Department of Agriculture's Cereal Station at Ballincurra, Midleton, Co. Cork, Ireland—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (July 17).

Assistant Lecturer in the Department of Philosophy—The Registrar, The University, Manchester 13 (July 21).

Lecturer in Geology—The Head of the Department of Geology, Imperial College of Science and Technology, South Kensington, London, S W.7 (July 21).

Fellows (men or women graduates of any university) in Carbohydrate Chemistry—The Principal, Royal Holloway College, Englefield Green, Surrey (July 23).

Lecturer (with training or experience in one of the following fields: (*a*) hydraulics; (*b*) aerodynamics; or (*c*) hydrodynamics) in the Department of Fluid Mechanics—The Registrar, The University, Liverpool (July 23).

Lecturer/Senior Lecturer in Electrical Engineering at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 27).

Lecturer in the Department of Mechanical Engineering—The Registrar, The University, Liverpool (July 28).

Soil Microbiologist (with a good honours degree and practical experience)—The Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, Sussex (July 29).

Assistant (graduate in medicine, biology, psychology, sociology, or any other social science) in the Department of Public Health and Social Medicine—The Secretary, The University, Edinburgh, (July 31).

Assistant Lecturer (with special qualifications or interests in radio astronomy) in Physics—The Registrar, The University, Manchester 13 (July 31).

Lecturer in Anatomy—The Registrar, The University, Manchester 13 (August 7).

Lecturer in Education, at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C.1 (New Zealand, August 15).

Lecturer in the Department of Botany, Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, August 15).

Chair of Electrical Engineering at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 31).

Lecturer in the Department of Zoology, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, September 1).

Assistant Chemist (with a degree in chemistry, agricultural chemistry or A.R.I.C., or about to qualify) for analytical work on crops and soils—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1052/7.

Assistant Experimental Officer (male, with G.C.E. advanced level in science subjects, including mathematics and chemistry, or equivalent qualifications) in the Analytical Section, Medical Division, for work involving the analysis of radioactive and other toxic agents in biological specimens and in air—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Didcot, Berks. quoting Ref. 541/34.

Assistant Professor in the Department of Anatomy—Prof. R. L. de C. H. Saunders, Dalhousie University, Halifax, Nova Scotia, Canada.

Biochemist (with a first- or second-class honours degree in biochemistry or equivalent qualification, with postgraduate research experience), to study the chemical properties of cervical mucus in relation to the action of sex hormones—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 56/3.

Biochemist (with Ph.D., M Sc., or equivalent qualification) to engage in research on the biosynthesis of proteins—The Secretary, Courtauld Institute of Biochemistry, Middlesex Hospital Medical School, London, W.1.

Chemistry Master, to teach to advanced level—The Headmaster, The Hall, Repton, Derbyshire.

Head of the Chemistry Department—The Director of Research, British Cotton Industry Research Association, Shirley Institute, Manchester 20.

Lecturer (with an honours degree in metallurgy and preferably with industrial and research experience) in Metallurgy—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3

Principal Lecturer (with research experience, and preferably industrial experience) in Ceramic Materials in the Department of Metallurgy—The Secretary-Treasurer, Royal Technical College, George Street, Glasgow, C.1.

Research Assistant (with Inter. B.Sc. or equivalent qualification in chemistry or metallurgy) to assist in the general work of the Corrosion Section of the Chemistry Department, and in particular to assist in research on rust resisting steels for aircraft—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "C.R.1".

Senior Lecturer in Inorganic Chemistry; and an Assistant Lecturer, Grade B, in the Physics Department—The Acting Principal, Royal Technical College, Salford 5,

GOVERNMENT RESEARCH IN GREAT BRITAIN

THE debate in the House of Commons on the second reading of the Department of Scientific and Industrial Research Bill on June 20 ranged over numerous aspects of the organization of research in Britain, though without pressing home the vital questions more than had been done earlier in the House of Lords. The proposal to change the Advisory Council into an executive body met with a lukewarm reception, nor was the financial clause debated at that stage. Mr. F. Willey's reference to the quinquennial principle drew from Mr. J. R. Bevins a reminder that there is an agreement about expenditure on a five-year basis between the Department and the Treasury; but there was no searching discussion of the problem of Parliamentary control in relation to the efficient conduct of research.

No more than in the House of Lords was there any serious criticism of the work of the Department of Scientific and Industrial Research, though there was some criticism of the Advisory Council for Scientific Policy, Mr. J. Callaghan suggesting that its reports were virtually ignored by the Lord President of the Council. Mr. Callaghan asked for a statement of Government policy, including a review by the Government of the organization and co-ordination of our scientific effort. He suggested also that a survey should be made of research projects, so that it would be possible to see what needs to be done but is not being undertaken either by industry, the universities or by other institutions. He also pressed once again for a Minister in the House of Commons bearing some responsibility for the scientific effort of Britain and able to deal with questions from his own experience and first-hand knowledge.

Sir Hugh Linstead supported much that Mr. Callaghan advocated, though he pointed out that finance alone will not assure effective research or provide the conditions in which research is most fruitful, and he uttered a warning both against undue Government co-ordination and excessive preoccupation in Parliament with the financial aspect, since the limiting factor in the scientific and technological spheres may well be men. Sir Hugh emphasized, moreover, that it is virtually impossible for major research to be undertaken in Britain without Government direction, and whether it liked it or not, the Government is bound to take a much closer interest in what is going on and to have an increasing say in the selection of projects and the places and the men who do the work. He appeared to look rather to the quality of the men who serve on the Council than to any formal change in organization to secure the necessary co-ordination, and he suggested that the relative distribution of the energy and resources of the Department requires reconsideration. Sir Hugh recognized, and indeed stressed, the importance of disseminating information, but suggested that forty-five per cent is too high a proportion of the Department's effort to be devoted to advisory and like services, and that the responsibility for disseminating information might well be shared with other organizations.

That is certainly a matter for examination. A large part of the value of the industrial research associations is derived from their educational influence on the industries they serve, and it would not be easy to separate sharply their advisory and educational work from research work in the usual sense of the word, whether pure or applied. The estimate of the Advisory Council quoted in the debate relates to the work of the Department as a whole: for the research associations it could well be different, and Mr. J. H. Dunning's study in the June issue of the *District Bank Review*, which was quoted in the debate, suggests that a major part of their effort, as against the 30 per cent estimated by the Advisory Council for the Department as a whole, is devoted to basic research. Moreover, as Mr. Austen Albu pointed out, in referring to the work of the Intelligence Division of the Department, which is responsible for the dissemination of the results of research, the National Reference Library of Science and Invention and the National Science Lending Library could play an important part here. The failure of the Government to take any steps to implement these recommendations of the Advisory Council on Scientific Policy or to establish the National Science Centre not only hinders the work of the Department but also tends to perpetuate existing waste and overlapping of effort. Indeed, the conversion of the former Advisory Council into an executive body, if it means anything at all, would seem to make the provision of such means for informal contact the more important if we are to avoid the rigidity of control which all participants in the debate recognized as one of the great dangers attending Government direction of research. The early establishment of a National Science Centre would contribute not merely to the more efficient dissemination of existing knowledge, but also to the establishment of the right climate for the encouragement of science and scientific research.

Mr. Herbert Morrison made no comments on this matter, but was convinced that the Lord President of the Council could make a most important contribution to the work of the Research Council, though he attached little importance to the change of function from advisory to executive. Clearly, though Mr. Morrison implied rather than stated this, the Lord President's other responsibilities should not be such as to encroach on this prime responsibility for watching over the scientific work of the Government and the research effort of the nation in general. Given the time and interest, the Lord President could, without exercising executive responsibility, do much to keep the research effort in balance, to see that projects are discontinued when no longer of real significance, and generally provide the encouragement and stimulus needed for effective research.

Mr. Morrison's experience led him to lean rather to the advisory committee system of securing expert advice as to the selection and discontinuance of projects. Nor did he press the point about representation in the House of Commons. That was, however, put forcibly by Mr. Eric Fletcher, who, recognizing that it may not always be practicable for the Lord President to sit in the House of Commons, argued convincingly that, when this happened, some other senior Minister, such as the Lord Privy Seal, should be entrusted with the responsibility for answering for scientific matters from his own knowledge and place in the Cabinet.

The debate thus ranged far outside the work of the Department of Scientific and Industrial Research, and was indeed a discussion of the adequacy of the research effort of Britain. Misgivings were expressed as to the extent and balance of that effort; but there were few positive suggestions for improvement, though its close connexion with technological education was clearly appreciated. Sir Hugh Linstead, for example, referred to the part which the technical colleges could play in research if they received adequate grants, and suggested that this is a matter to which the new Research Council should turn its attention.

It is obvious that members of Parliament took a very wide view of the responsibilities of the new Research Council, and at times seemed to stretch them to overlap with the responsibilities of the Advisory Council for Scientific Policy. Admittedly, the Bill does not limit the responsibilities of the Research Council to the work of the Department of Scientific and Industrial Research, nor does it offer any contribution to the prevention of duplication of research effort or research grants through other Departments of State. The need persists for a closer look at the whole Government organization, for at present research grants for the universities may come through the University Grants Committee as well as the Department of Scientific and Industrial Research, research grants for the technical colleges from the latter and through the Ministry of Education, while, as the Select Committee on Estimates has stressed, research in defence departments such as the Admiralty is liable to involve risk of duplication on a large scale.

This matter of overlapping was emphasized by Mr. M. Philips Price, who, recognizing that it cannot be dealt with by the Bill and that it is not entirely a matter for the Lord President of the Council, suggested an investigation of the whole question of overlapping of research in Civil Departments, in the Service Departments and in the field of nuclear energy. This need to reduce overlapping and obsolete research was one of the main points reiterated in the debate, and two aspects of it were particularly stressed: our lack of information as to the extent of our research effort or even as to the gaps in that effort, and, less prominently, as a corollary of eliminating waste, the possibility of more co-operation and pooling of effort. The importance of a clear system of priorities was also stressed, and Mr. J. Idwal Jones also advocated more independent research institutes, besides extending research at the universities and technological and technical colleges. Apart from an indirect reference by Mr. H. Brooke, the Financial Secretary to the Treasury, in concluding the debate, to the importance of safeguarding university autonomy, however, little reference was made to the problems of financing research in universities by outside bodies which were discussed at the last Home Universities Conference.

Mr. Callaghan quoted a recent reply from the Treasury giving Government expenditure on scientific research and development as £235 million, of which only £31 million is on civil research, and he asserted that of 10,000 scientists employed by the Government about 7,500 are engaged on defence research and development. Mr. Albu estimated the total expenditure on research in Britain as about £300 million, of which between £50 million and £70 million is by industry. A recent lecture to the Institute of Physics by Sir John Cockcroft put the expenditure of industry on research for its own purposes as more than £40 million. As between fundamental research, civil applied research and defence research, he estimated that as against £200 million on defence research and more than £60 million on civil applied research, £5 million is expended on fundamental research at the universities and another £5 million in fundamental research in government and semi-government institutions, about ten per cent of the total graduates engaged on research being occupied with fundamental research.

This expenditure of rather less than five per cent of research effort of Britain on fundamental research compares with 7 per cent in the United States; and while per head of population the research and development labour force works out at about the same in the two countries, as also, allowing for differences in the value of money, do the costs of research, Mr. Dunning in his article referred to above estimates that, discounting the difference in money values, the average American firm carries out 2·5–3·5 times more research than the average United Kingdom firm. The United States are also outstripping Britain in the rate at which they are adding to their scientists and technicians, the output of graduates in engineering and applied sciences in 1954 being 136 per million of the population compared with 57 in the United Kingdom. Mr. Dunning also estimates that the parent companies of the hundred most important American subsidiaries manufacturing in Britain spend more each year, in real terms, on research and development than the whole of British industry combined, and that the size of the average parent company is five to ten times that of the subsidiary, in terms of labour force.

Such comparisons were not given undue weight in the debate in the House of Commons; they were used rather for emphasizing the relevance of technical education to the research potential of Britain. Moreover, it was also recognized that a part of the shortage of scientific man-power arises from failure to use it to the best advantage. Even if the shortage is not eliminated in this way, as Mrs. M. Jeger suggested, it would undoubtedly be alleviated by making sure that existing resources are used wisely and with the planned forethought that is appropriate for any scarce commodity. The main point is the lack of accurate and full information on which to form sound judgments of the magnitude and disposition of the existing effort of Britain: even in regard to the alleged loss of scientific man-power overseas, information seems to be incomplete.

None the less, the absence of such information, while it restrained criticisms in the debate and particularly suggestions as to neglected fields of research, does not invalidate Mr. Dunning's broad conclusion that for sheer volume of research expenditure, and without considering the question of research efficiency, the United States command a lead over the United Kingdom which, because the results of research are cumulative, is likely to grow. The concern expressed in the debate as to the balance of research effort did not reflect any desire to curtail expenditure on fundamental research, either by the Department of Scientific and Industrial Research or at the universities, or to increase the total expenditure without due consideration of the objectives. Concern was obviously entertained as to the proportion of resources going into nuclear research. Sir John Cockcroft has estimated the number of scientists and technologists working on nuclear power as about 1,000 out of the 58,600 which Sir Harold Hartley gives as the total employed in Britain on research and development. Nor, while it was recognized as necessary that particular projects should be terminated and that research programmes should be continuously re-examined, was any real uneasiness expressed about overlapping. As Mr. Brooke remarked, a certain amount of overlapping may be fruitful: it is much more important to close any serious gaps in the advancing front of research, and we must have the knowledge that enables us to do so.

While, however, Mr. Dunning's article was quoted in the debate, his suggestions regarding co-operation in research and the pooling of results received no comment. Mr. Dunning regards the structures of the United States and the United Kingdom as complementary rather than competitive, and considers that the chief source of anxiety so far as Britain is concerned is likely to be over Continental and Asiatic competitors. To make the best use of the limited resources of Britain and so meet the demands of the future, he suggests that we should specialize in those stages of manufacturing and research to which our productive resources are comparatively the most suited, and exchange the knowledge and expertize acquired in these fields for that attained in fields to which the productive resources of the country are less well suited. Industrial development in Britain already benefits directly from the competitiveness and dynamic quality of the American system, and Mr. Dunning indicates how the gap between the discovery of a new product, process or material and its full acceptance and marketing is being bridged by the presence in Britain of firms financed from the United States.

There is an important point here bearing on the research organization and potential of Britain which was missed in the debate. If, in the way just noted, British industrial achievement is linked with an economic environment more favourable to exploitation, while the American economy benefits from the fundamental research carried out in Britain which the United States can often apply to their great advantage, we cannot be content for British firms to concentrate on fundamental research while their American associates develop and commercialize the results. Nevertheless, research co-operation in this way does offer mutual advantages in specialization, and in time the production and selling technique will be made available to British firms.

What needs to be remembered is that Britain cannot afford to rely entirely on such co-operation. There are fields in which it is vital to prosecute research independently; and in any event, undue reliance on American facilities may tend to stifle initiative and development. Co-operation will always be easiest and most fruitful when there is the right climate of opinion on both sides; and, in Mr. Dunning's opinion, while a freer exchange of knowledge between United Kingdom firms, regular visits by industrialists to the United States, and better publicity may all help, it is even more important to reconsider features of the economic and fiscal policy of Britain which tend to discourage initiative and enterprise.

That is one, but not the only, reason for taking the discussion of the Government organization of and support for research, whether fundamental or applied, out of party politics; and though this relation of research to fiscal policy was not mentioned in the debate, the discussion was refreshingly free from political partisanship. Mr. Brooke remarked in concluding the debate that we must seek a system which can preserve the freedom of the universities, the freedom of the scientist, and allow the Government to apply its resources so as to fill the gaps and stimulate the best possible work in the right directions for the whole of the industrial and scientific field. From that there would appear to have been no real dissent in the House. Only Mrs. Jeger appeared to recognize that we have still to learn much about the most economical and fruitful way of financing research in the universities, where it is now estimated that some 14 per cent of the university budget, or nearly £4·5 million in that for 1953–54, is represented by external support for research, half of which comes from the Government. Of this total, some 20 per cent of the resources of the departments of science and technology are devoted to work of direct interest to industry; and as both Dr. V. E. Cosslett and Prof. H. W. Melville pointed out at the Home Universities Conference last winter, we are only at the beginning of discussions on how best to regulate the impact on the universities of the growing interest of industrial and other external organizations in project research and to secure that there is not excessive concentration in particular fields, such as nuclear research, to the neglect of others.

The debate in the House of Commons has accordingly demonstrated the wide opportunities open to the new Research Council, although it may not have made clear how far its functions may overlap those of the Advisory Council on Scientific Policy. The Government, moreover, should have been left in no doubt as to the urgent need to take the steps required to fill the gaps in public knowledge of the present disposition of the research effort of Britain, and particularly as regards defence research. Parliament and the scientific and technological world must be given the information essential for a sound judgment as to the way in which resources of the country are distributed in research in order to ensure that wise decisions are taken as to the gaps to be filled or the overlapping to be eliminated. Such information is essential for effective co-operation within Britain itself and also in active partnership with the United States, as Mr. Dunning suggests. The continuing debates on the Bill afford further opportunities which should be utilized to promote public understanding of what is required and to supply the goodwill and esteem which the new Research Council—and also the Advisory Council for Scientific Policy—requires to enable it to carry out its work effectively; and to ensure support for the recommendations and decisions in regard to the Department of Scientific and Industrial Research for the furtherance of research in Britain generally needed for firm action and sustained results. The debate on the second reading of the Bill at least warrants the hope that further discussions on it will proceed in an atmosphere which will facilitate and not obstruct the appointment to the new Research Council of scientists and industrialists of outstanding qualifications and abilities, and not simply representatives of particular interests.

GEOLOGICAL RECORDS OF RADIOACTIVE EVENTS

Nuclear Geology

A Symposium on Nuclear Phenomena in the Earth Sciences. Edited by H. Faul. Pp. xvii+414. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1954.) 56*s.* net.

THE new subject of radioactivity has influenced many older branches of science; but no discipline—with the obvious exceptions of physics and chemistry—was more profoundly changed by it than geology. It may suffice to recall how fundamentally its whole time-scale has been altered; when, in the second half of the past century, Lord Kelvin declared that "as an abode fitted for life" the Earth cannot have served for more than 20 to 40 million years, it was very hard for geologists to oppose him, since he was in possession of all the relevant scientific facts—except those concerning the liberation of nuclear energy. This almost unlimited source of heat was discovered only towards the end of his life through the study of radioactive elements. Now the time which the astrophysicist can grant to the geologist has been increased more than a hundredfold and, more important still, several methods based on radioactivity have been put in his hand by which he may try to determine this figure experimentally with an accuracy never hoped for previously.

It is only natural that in the present volume, with its rather unusual title of "Nuclear Geology", considerable space is devoted to these determinations of geological age; but, to do justice to the ambitious title, an attempt is made to discuss also many other geological problems which appear now in a new light after radioactive data have been applied to geology. As the book is mainly meant for geologists and not for nuclear physicists, the first chapter, on fundamental considerations, instruments, and techniques of detection and measurement, will be found useful. It is preceded by a historical introduction which enumerates the early discoveries by radioactive workers which were of importance to geologists. (It is not quite correct to say (p. 5) that the work of Richards and Lembert on the atomic weight of radiogenic lead "first *proved* the theory of radioactive decay"; besides the fact that Hönigschmid's identical work was carried out quite independently and made public at the same meeting, the considerably earlier experiment by Ramsay and Soddy on the production of helium from radium has obviously greater claim to that description.)

The introductory paragraphs are followed by chapters on the occurrence of uranium, thorium, potassium and the inert gases in Nature, on the production of heat inside the Earth by radioactive processes and the help nuclear methods may give to geophysical exploration; also the subjects of radiation damage in minerals and of the influence of radioactivity on the formation of petroleum are discussed.

The subjects mentioned cover such a wide field that the editor was well advised to enlist the help of a great number of experts (twenty-six, in fact); he was prepared to sacrifice "uniformity of view, coverage and style" in order to gain "intangible freshness and clarity which are preserved only in first-hand accounts". This is admittedly the right procedure so long as isolated chapters are concerned which can stand by themselves. However, that such divided work cannot hope to achieve everything is convincingly explained by the author of the last chapter, on the origin of the Earth. Here Prof. Harold C. Urey begins with the assertion: "It is not possible to discuss the origin of a chondritic meteorite without attempting to understand the origin of the entire solar system; in fact, the latter subject cannot be discussed separately from the problem of the evolution of stars". He deplores the fact that astronomers and physicists have attempted to explain the origin of the solar system without possessing the necessary chemical knowledge, and then presents the relevant facts about the widely varying abundances of the chemical elements. He discusses possible explanations based on the volatilities of the elements (which are known) and the temperatures prevailing at certain stages of the Earth's history (which must be conjectured); and he concludes that "much more" must be learned before a "definite and lasting model of the origin of the solar system and of the Earth is devised". It is apparently Prof. Urey's opinion that one man will have to study and digest this vast amount of facts, before any effort to solve the riddles of the solar system can succeed. We may remember that, guided by a similar ideal, near the end of his life Alexander von Humboldt wrote the encyclopædic "Kosmos", and that Goethe, too, had the ambitious aim, neatly expressed by the scholar and poet Friedrich Ruckert:

> Eh es sich rundet in einen Kreis,
> Ist kein Wissen vorhanden;
> Solang nicht Einer Alles weiss,
> Ist die Welt nicht verstanden.

F. A. PANETH

AMMONITES AND CHRONOLOGY OF THE JURASSIC

Jurassic Geology of the World

By Dr. W. J. Arkell. Pp. xiv+806+46 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1956.) 105s. net.

THE author of "The Jurassic System in Great Britain" (1933) has capped that notable work with this equally substantial volume. Starting with Great Britain, where the succession of Jurassic formations was first determined, Dr. W. J. Arkell conducts his reader on a world tour, continent by continent, giving for each region a concise account of the rocks of this system and a critical review of the evidence as to the exact stages which they represent. Ammonite assemblages are the dominant theme throughout the work, the object of which, Dr. Arkell states, is in "no small part . . . to test the principles and performance of palæontological correlation on a world scale, to establish its capabilities and limitations". Bibliographies are given for each region, and Jurassic outcrops are indicated in numerous sketch maps. Some previously unpublished matter has been incorporated. The work is a mine of information and will be indispensable for reference.

Many will remember the controversies which, thirty years or more ago, centred around S. S. Buckman, who taught that ever-increasing precision was possible in the correlation of Jurassic rocks throughout the world on the basis of the distribution of ammonites, if only specimens were accurately collected and very critically examined. His culminating effort was to produce a scheme of about 370 'hemerae' into which, he alleged, it was practicable to divide Jurassic time. Ammonite evolution and the universal dispersal of new forms were, he maintained, so rapid that, if marine rocks deposited during any one of these hemerae were present in any region, the ammonite assemblage which then flourished everywhere would be found in them; and the absence of any such assemblage would indicate a local gap in the rock succession. A few thought that Buckman's scheme was entirely based on careful field-work (he certainly knew the Middle Jurassics of the Cotswolds thoroughly), others regarded him as a prophet who had divined the truth; but there were unbelievers who pointed out that his ideas were contrary to present-day experience of faunal provinces and the dependence of distribution on ecological factors. His doctrines were, at least, a stimulus to accurate collecting. Time has now put them to the test, and we turn with interest to Dr. Arkell's pronouncements on the subject.

That the rapidly evolving, prolific and (apparently) mostly very mobile ammonites afford the most reliable basis at present known to us for the correlation of marine Mesozoic rocks is a universally accepted fact. In the Lias, moreover, there is very little evidence of the existence of faunal provinces, the distribution of many genera being world-wide. As we ascend in the Jurassic succession, however, three faunal provinces (Tethyan, Pacific and Boreal) become distinguishable, contesting for certain regions. In the most favourable circumstances, where rocks of suitable lithology occur, a considerable degree of precision in correlation within a restricted area is possible with the aid of ammonites. Over any wide area, however, zonal schemes, much less detailed than those of Buckman, break down, and the original series of zones promulgated by Oppel in 1856–58 (amounting to about one-tenth the number of Buckman's hemerae) lies at about the limit of practical utility. Further, Dr. Arkell's considered view is that the original eleven stages into which d'Orbigny divided the Jurassic system in 1850 form "by far the best scheme yet devised for classification on a world scale". Even these are not applicable universally for the uppermost Jurassic; here we still have no means of exact correlation between d'Orbigny's Portlandian and Purbeckian in north-west Europe, the Volgian of Russia, and the Tithonian of the rest of the world. These conclusions are both a testimony to the acumen of the pioneers and a reminder that applied palæontology cannot be expected to progress on the same lines as a mathematical science. An interesting episode in the history of palæontological theory must be considered finally closed.

The concluding chapters of the work deal with other matters of general interest. Dr. Arkell is on the side of those who advocate the permanence of the main ocean basins. He has no use for palæogeographical maps, especially those showing continental masses occupying the present North Atlantic and Pacific basins in Jurassic times. Of continental drift since the Jurassic, he finds no evidence.

L. R. Cox

PROGRESS IN NUCLEAR SCIENCE

Annual Review of Nuclear Science

Vol. 5, 1955. Edited by James G. Beckerley, in association with Martin D. Kamen and Leonard I. Schiff. Pp. x+448. (Stanford, Calif.: Annual Reviews, Inc., in co-operation with the National Research Council of the National Academy of Sciences, 1955.) 7 dollars.

THIS is the fifth volume to appear in this series. The individual articles range widely from theoretical nuclear physics through nuclear engineering and radiation chemistry to radiobiology. Such publications must eschew the ephemeral progress report, the too-specialized description of experimental work or the very general treatment which properly belongs in a text-book. This volume generally avoids these hazards. The literature surveys are up to date to within about a year ago.

In a review of present knowledge of electromagnetic transitions in nuclei, Goldhaber and Weneser discuss the relative success of various nuclear models in explaining the regularities observed experimentally. Ford and Hill discuss the recent experimental information that has led to a detailed and consistent picture of the charge distribution in the nucleus. Theoretical explanations of this distribution, however, still seem inadequate. Peaslee contributes a survey of a field which has been receiving much attention recently—that of nuclear reactions in the intermediate energy-range up to 20 MeV. Here the compound nucleus model is ceasing to be applicable, and the more direct knock-on processes familiar at high energy have not yet become predominant. Two extreme models, the optical model and the statistical model, have each had some success. However, the experimental information available so far is rather incomplete.

Fretter supplies a useful article of the handbook type on the cloud chambers and bubble chambers being exploited in high-energy physics. Blizard discusses radiation shielding, a vexing technical problem for reactor or accelerator designers since the shielding represents such a large fraction of the cost. Borst compares designs of reactors intended for research purposes. Much of his discussion is of particular installations in the United States, but some of his remarks have general application. A few recent industrial problems where the mass-spectrometer has been used are reviewed by Berry and Walker.

Three articles are on radiation chemistry: a review of recent work by Dainton; a discussion of chemical effects of low-energy electrons by Krauss, Wahrhaftig and Eyring; and a useful compilation of radiochemical separation procedures by Finston and Miskel. Four articles on radiobiology complete the volume: cellular radiobiology, by Mortimer and Beam; removal of radioelements from the mammalian body, by Schubert; vertebrate radiobiology (physiology), by Edelmann; and a technical survey of radioautographic methods, by Norris and Woodruff.

The large amount of new data reviewed in these articles indicates the rapid growth and complexity of this field. The book is well produced and fully indexed. E. B. PAUL

UNIVERSITY OF SHEFFIELD

The Story of a Modern University

A History of the University of Sheffield. By Arthur W. Chapman. Pp. xvi+551+38 plates. (London: Oxford University Press, 1955.) 50*s*. net.

TO the student of higher education in Great Britain the past decade has been a period of great significance, for it has seen, among other developments, the creation of four new universities. Despite the great social, economic and political changes which have followed upon two World Wars, these years resemble, at least in the creation of universities, the first decade of this century, when a number of the civic universities of Britain were founded.

In "The Story of a Modern University", Dr. Artuhr W. Chapman recounts the growth of one of these—the University of Sheffield—which received its royal charter in 1905, and which to-day has some two thousand students in six faculties. Dr. Chapman has traced, with meticulous care and skill, the development of the University and its forerunners over a period of more than three-quarters of a century. Such an achievement has required from him an intimate knowledge, not only of the University, but also of local aspirations, and those national trends which contributed to its creation, as well as an appraisal of the personalities of the stalwarts who led the movement for a university in Sheffield.

The University has indeed been fortunate in its historian, for Dr. Chapman brings to his task an unusually long and varied experience of it. He has been a member of the staff for more than thirty-five years, and has served the University with rare devotion and enthusiasm. For two decades he taught in its laboratories and lecture rooms, for almost a decade he was warden of its largest hall of residence, and for the past twelve years he has been its registrar. With this rich experience he has been able to deal sympathetically with both the academic and administrative sides of its development.

Dr. Chapman's book is, however, more than a history of a particular university. It epitomizes a movement which, during the past hundred years, has revolutionized higher education in Britain. An outstanding feature of this work is an admirable collection of pen-portraits of such leaders as Mark Firth, Henry Stephenson and W. H. Hicks, "the academic founder of the University".

This is a scholarly work, beautifully produced, with many excellent reproductions of portraits of the University's leading personalities over the years. It will be read with real pleasure and satisfaction by all who cherish and support our universities, and it might, with advantage, be read by many students to-day, who do not always appreciate the wealth of their inheritance. BRYNMOR JONES

CHEMISTRY IN THE PETROLEUM INDUSTRY

The Chemistry of Petroleum Hydrocarbons

Edited by Benjamin R. Brooks, Cecil E. Boord, Stewart S. Kurtz, Jr., and Louis Schmerling. Vol. 2: Pp. vi+448. 108*s*. net. Vol. 3: Pp. vii+690. 144*s*. net. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1955.)

THESE two volumes now follow Vol. 1, published in 1954, and present an extensive body of information and ideas on a wide range of topics, which can more or less be included under the general title of "The Chemistry of Petroleum Hydrocarbons". The title is, in fact, interpreted liberally, and these are far from being text-books of pure chemistry. In many cases the subject-matter is treated largely from the point of view of current practice in the petroleum industry. Vol. 3, for example, begins with a short chapter on the oxidation of *ortho*xylene to phthalic anhydride. This particular section, which might well be glossed over in a text-book on chemistry, is introduced because of the uncertain supply of naphthalene in the United States and the consequent importance of this alternative route to phthalic anhydride. These two volumes are the work of forty-four contributors, and the coverage is thus comprehensive.

The specialized contributor to volumes such as these must be allowed freedom to follow his own ideas on the important current trends in his own field, since only in this way can each author contribute his detailed knowledge to the total presented. The editors of the volumes, on the other hand, must inevitably seek to achieve some unity of style and treatment, in addition to seeing that the whole field is adequately covered: they will seldom be in a position to criticize specialized detail. In the same way, the reviewer will focus his attention on the overall picture presented by these volumes, which must then be judged on the success achieved in selecting and unifying the contributions of the many authors. In justice, one might claim that multi-author volumes such as these should have multi-reviewers!

It need scarcely be said that the general presentation is excellent. Printing and paper are of high quality and printing errors are almost non-existent. There is, however, a certain unevenness in the individual chapters. Considering the form of the book in the preface, the editors conclude that "it would be necessary to limit its scope to scientific fundamentals". Many of the chapters conform to this idea. Yet the chapter on conditions and results of thermal cracking, though excellent in itself, ends with details of the design calculations illustrating "the adaptation of an existing furnace to a Visbreaking operation". An extensive chapter on the theory and mechanism of aromatic substitution forms a splendid digest of this much-studied subject. A later chapter deals further with the theory of nitration, but surely the information that nitrobenzene is also called oil of mirbane and smells of bitter almonds could be left to the junior text-books.

The subjects dealt with in the two volumes cover a wide range. Vol. 2 deals mainly with pyrolysis (including catalytic cracking) and oxidation of hydrocarbons and includes, among others, excellent sections on pyrolytic reactions of aromatic hydrocarbons, the theory of catalytic cracking, mechanisms of the reactions of non-benzenoid hydrocarbons and the theory of hydrocarbon oxidation. In Vol. 3, the chapter on fluorination of paraffins and cycloparaffins seems rather brief, and it is surprising at first sight to see a chapter on the chemistry of natural and synthetic rubbers: this is logical, however, when the present trend towards synthetic rubber is considered. This volume includes also excellent chapters on vinyl polymerization and on catalytic hydrogenation.

These volumes can be recommended as a valuable and convenient source of information on petroleum chemistry, particularly from the industrial point of view. In addition, they include excellent survey chapters on a good deal of fundamental chemistry. If one must regret that the great bulk and pace of modern development make it difficult for any one man to collate and present the published knowledge in this field, the present editors and authors are to be congratulated on producing this much order out of the vast mass of available information.

LEIBNIZ AND NEWTON

The Leibniz–Clarke Correspondence

Together with extracts from Newton's "Principia" and "Opticks". Edited with Introduction and Notes by H. G. Alexander. (Philosophical Classics.) Pp. lvi + 200. (Manchester: Manchester University Press, 1956.) 16*s*. net.

THE beginnings of modern science are rightly located in the seventeenth century, not only because of the positive achievements of that time, but also because it was then that the kinds of explanation which have come to be regarded as scientific were first thrashed out in philosophical discussion. Now that the broad principles of what constitutes a scientific explanation have come to be taken for granted, it is easy to forget that they emerged only after prolonged debate in which theologian, metaphysician and natural philosopher all took part, and in which indeed the major protagonists were well able to play all three parts at once. The correspondence between Leibniz and Clarke, now reprinted for the first time in English since 1738, represents the last phase of the battle. Leibniz died in 1716, only two weeks after Clarke's fifth letter had been dispatched, and no subsequent philosopher followed him in contesting the theoretical basis of science on purely metaphysical grounds.

It would be a mistake, however, to regard Clarke as the champion of enlightened science and Leibniz as the reactionary metaphysician. Much of the argument in this correspondence is of the kind that would now be called, in a pejorative sense, metaphysical, and neither Clarke nor Leibniz is concerned to make a distinction between questions of science and questions of metaphysics. With regard to theology, indeed, it is Leibniz who is the prophet of the new age, for he wishes to assert its distinction from and independence of science, but he sees this distinction as a safeguard for the doctrine of the uniqueness and transcendence of God rather than as a declaration of independence by science. This was the point upon which the controversy began. In 1715 Leibniz wrote to Caroline, then Princess of Wales, that the philosophy of Sir Isaac Newton was contributing to the decay of natural religion in England, for Newton had said that space is an organ by which God perceives things, thereby making things independent of God who created them, and also that God needs to intervene in the universe from time to time to maintain its order, like an unskilful workman who has made a machine which constantly needs repairing. This provoked Clarke to reply, as a churchman and disciple of Newton, and the correspondence continued through Princess Caroline for a year, five letters passing on either side. Its subject-matter was soon extended to include Leibniz's own metaphysical principles, and scientific topics such as the nature of space and time, the existence of vacuum, and the theory of gravitation.

On these scientific questions the argument turns upon what kind of theory is to be admitted in science, and in each case it is Leibniz who insists that theoretical explanations must conform to what he regards as self-evident metaphysical principles. There is no disagreement about the facts—Leibniz knows as well as Clarke that space void of air is produced in Torricelli's barometer and Guericke's air-pump, and that the planets move around the Sun in curved paths—it is the Newtonian explanation of these phenomena in terms of material atoms exerting forces upon each other across a void that he contests. There cannot, he says, be indistinguishable atoms because there would have been no sufficient reason for God to have arranged them in one order rather than any other, and God does not act without sufficient reason; and there cannot be a void because the universe would be imperfect if it did not contain as much matter as possible. Clarke disputes these arguments on theological grounds. He agrees with Leibniz, however, that nothing can act where it is not present, only maintaining, as Newton had done, that gravitational attraction is a fact, however it may be explained. If Leibniz can explain it by the laws of mechanism, he says, he will "have the abundant thanks of the learned world". Clarke's tendency throughout is to allow no restriction on the kind of explanation which may be given, and he is prepared to contemplate the direct action upon matter of immaterial, insensible substances as well as the direct intervention of God.

If there is any moral to be drawn, perhaps it is that science needs both Leibniz and Clarke. There is always some limitation on the kind of theory which is useful at any particular stage, and in 1716 Leibniz was right to question Clarke's immaterial substances and non-mechanical explanations. But preconceived ideas about what kinds of theory are proper can become too rigid, as physics learned again in the nineteenth century.

Mr. H. G. Alexander contributes notes and a critical introduction which contains an excellent account of the controversy on the nature of space and time as it appears in Newton, in the Correspondence, and afterwards, concluding with some remarks on the theory of relativity.

MARY B. HESSE

TUBE INVESTMENTS RESEARCH LABORATORIES

NEW HIGH-ENERGY RADIATION DEPARTMENT

By DR. A. CHARLESBY

IN recent years, interest in the civil aspects of the atomic energy programme has been mainly centred in the use of atomic energy for power production; radioisotopes produced in atomic plants have also found widespread application as tracers in industry, medicine and agriculture. A new and rapidly developing subject concerns the use of high-energy radiation to promote chemical changes, such radiation being available in atomic reactors.

Although the effects on materials of ionizing radiation in the form of alpha-, beta- and X-rays have been studied for a number of decades, the subject has received a sudden impetus in the past few years and considerable scientific and technical effort is now being devoted to it in a number of countries. This greatly increased interest arises from two main causes—the availability of powerful sources of radiation in the form of atomic piles or high-voltage generators, and the discovery of important applications of the knowledge gained from such studies. Information on the effect of atomic radiation on potential pile materials is essential in the design of high-power reactors. Moreover, recent research has shown that some of the changes induced by radiation, particularly in organic materials, may be of considerable industrial value.

The fields of potential application are extremely varied and include such diverse subjects as the sterilization of pharmaceuticals and foodstuffs, the production of mutations in plants, the initiation of chemical reactions as, for example, in the petroleum industry, and the production and modification of plastic materials. It is a measure of the rapid rate of progress in this field that although some of the basic discoveries were published only a few years ago, processes based on these have already reached the industrial stage. The field of application will undoubtedly extend with further research. Eventually, high-energy radiation may indeed supersede certain chemical treatments involving heat or chemical reagents. It has already been found that some processes which cannot at present be carried out by conventional chemical techniques become feasible by the use of high-energy radiation which can be applied in solids, liquids or gases at any desirable temperature.

Although the development of the subject is closely bound up with atomic energy, it should perhaps be emphasized that this relationship is largely of a historical character. The observed changes in physical and chemical properties arise from disturbances in the electronic structure and not from any changes in the nucleus. Of the sources available to produce such modifications, only a certain number rely directly or indirectly on nuclear transformations. These include the atomic pile itself, radioactive uranium rods withdrawn from atomic piles after use, or fission products which would otherwise be wasted. Naturally occurring radioactive elements or radioactive isotopes produced in the pile, such as cobalt or cæsium, may also be used for producing the required radiations. Chemical changes may be caused by alpha-, beta- or gamma-rays produced by such sources, either alone or together with the slow and fast neutrons present in atomic piles.

For most applications of radiation, beta- and gamma-rays appear to be most useful and convenient. Alternative sources of radiation are, however, available which do not rely in any way on nuclear changes, but instead depend on electrical high-voltage equipment, including linear accelerators, Van de Graaff machines, cyclotrons and X-ray equipment. It has been found that many of the effects obtained depend only on the energy absorbed within the material being irradiated and not on the type of radiation or its energy, which determines the penetration within the specimen. Thus, results obtained under certain experimental procedures can often be readily translated into those for very different radiation conditions. Experiments carried out with low-intensity fission products can be used for determining the feasibility of using radiations from high-power accelerators and, conversely, information obtained from the use of such accelerators can eventually be applied when fission products of high intensity become available with the growth of the atomic energy programme.

Until recently, work on the changes which can be produced by radiation have been largely confined to the use of low-intensity sources in universities and atomic energy laboratories; but the stage has now been reached where British industry is entering into the field. The equipment installed at the Tube Investments Research Laboratories, Hinxton Hall, Cambridge, is the first industrial installation designed specifically to pursue this work on a larger scale and with a greater degree of control of radiation conditions. To permit treatment with various types of radiation of different penetration and ionizing power, a number of radiation sources are available; these comprise a high-voltage accelerator giving 2 million volts, several X-ray machines and a large radioactive cobalt source.

The radiation building has been designed primarily to provide accommodation for the radiation sources and operating personnel; the preparation of specimens and the subsequent studying of the changes produced will normally be carried out in a separate laboratory building now under construction. The radiation building itself comprises a tower flanked by two small wings, one of which houses the smaller sources and the control gear for the main 2-million volt accelerator. This is installed in the upper of the two stories of the central tower and projects vertically downwards into the radiation treatment room on the lower story. The second wing of the building is used at present as a test laboratory, but is arranged for conversion to accommodate longer specimens which can be fed from one wing to the other through the radiation chamber. To protect personnel in the two wings against the intense radiation present in the radiation chamber, the walls consist of 3 ft. of concrete, while the heavy steel door is lined with lead. The radiation-level in the control room is constantly monitored and recorded. Specimens are

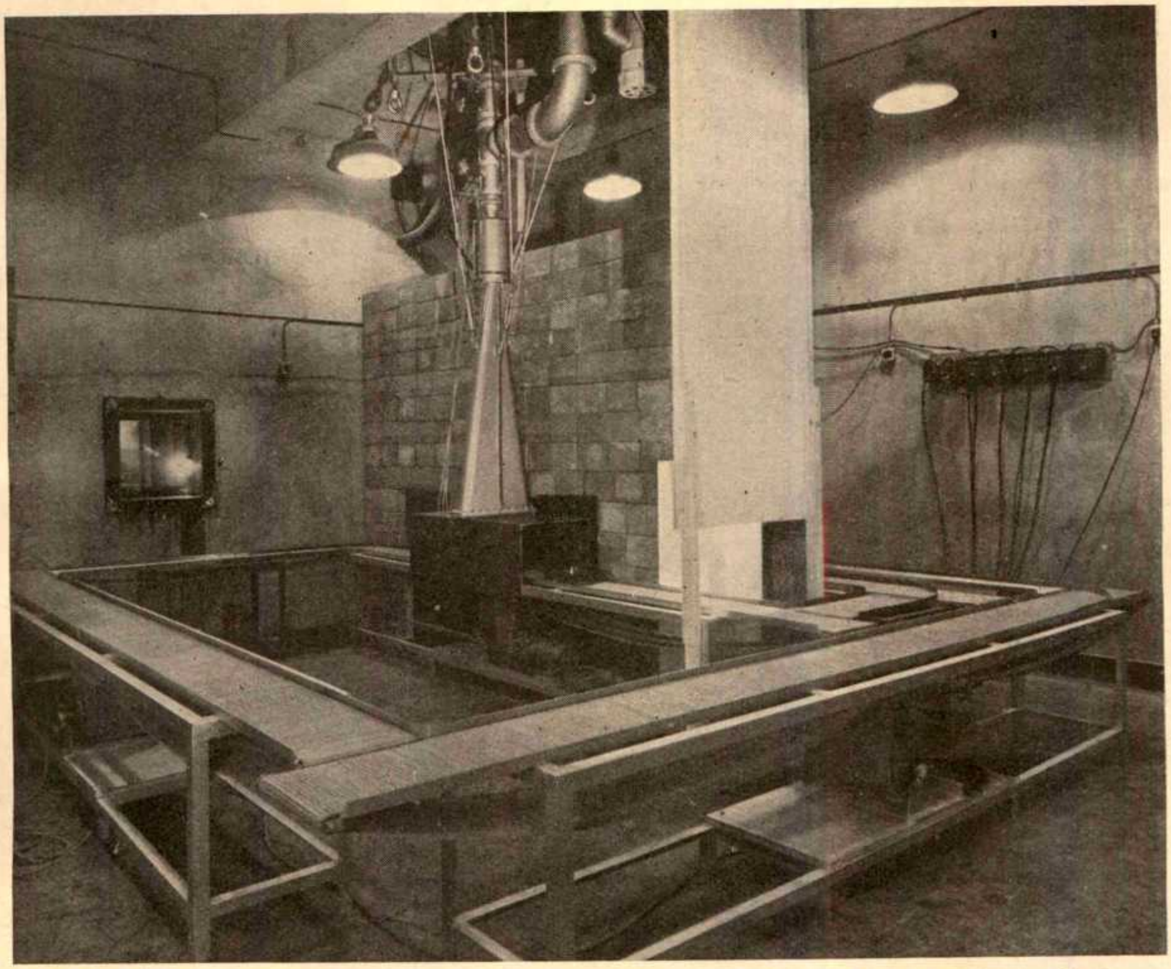

Fig. 1. General layout of the conveyor system within the irradiation chamber. The output tube for 2-MeV. electrons, showing the electromagnetic beam scanner, Faraday cage and viewing window can also be seen

led into the radiation chamber by a conveyor system passing through a labyrinth. A glass viewing-window approximately 1 ft. across allows specimens to be observed during treatment. This window consists of forty-one sheets of ¾-in. glass separated by medicinal paraffin oil to prevent multiple reflexions which would otherwise make direct vision impossible. A separate chamber houses the necessary ventilation and heating equipment.

The Van de Graaff electro-static generator supplied by the High Voltage Corporation, of Cambridge, Mass., is capable of producing an electron or ion beam of 2 million volts and of high intensity. By operating under a gas pressure of some thirty atmospheres, the total size of the installation has been considerably reduced. Under normal operation, it can generate 500 watts of electron-beam power, equivalent to the total radiation power available from many tens of thousands of curies of radioactive cobalt. By using an electron beam, the equivalent radiation intensity is even greater, since substantially all the energy emitted can be directed on to and absorbed within the specimen. Although most efficiently used for electrons, the generator can be converted to produce gamma radiation, fast protons or neutron radiation should these be required for special purposes.

Articles for radiation can either be placed immediately under the beam or fed from the control room by means of a flexible system of conveyor belts. The electron beam is scanned across each specimen by electromagnetic means controlled externally by the operator. The speed of the conveyor belt under the beam can also be varied over a wide range, and reversing mechanisms are available in the control room to enable specimens to be passed back and forth across the beam. Thus, a very wide range of radiation conditions can be readily obtained. After radiation, specimens may be taken out of the radiation chamber on the conveyor system and can then be handled immediately, since no induced radioactivity is produced with electron beams or gamma radiation of this energy-level.

In addition to the high-voltage accelerator, an X-ray machine operating at about 200,000 volts is available; this produces a radiation flux of higher penetration than from the 2-million volt electron beam, but the intensity is much lower. A second X-ray machine produces an intense beam of X-rays of up to 50,000 volts. Penetration of this radiation is very low and the equipment is mainly intended for surface treatment.

A high-intensity radioactive cobalt source gives highly penetrating gamma radiation of 1·3 million volts. This equipment has been designed to allow specimens to be irradiated at varying dosage-rates and at different temperatures. During the loading process, the cobalt source sinks into the base. To protect personnel during this operation, a number of interlocking devices are incorporated so that the container cannot be opened until the source is retracted into the safe position.

The programme of work envisaged with the radiation equipment includes both research and development. In the first instance, the effects of irradiating plastic materials are being studied in detail because it has already been shown that very useful changes can be produced in materials such as polyethylene, rubber and silicones.

At the same time, fundamental research is being undertaken into the mechanism by which radiation interacts with matter, and includes such problems as the irradiation of solutions, effects of inhibitors or protective agents, and the dependence on temperature of radiation-induced chemical changes. The investigation of radiation effects in materials may be considered as a new branch of scientific study involving close collaboration between chemists, physicists and biologists. Many of the effects observed are very novel, and their elucidation should provide not only a basis for further advances in radiation techniques and applications but also may well throw light on basic chemical reactions. The number of problems open for investigation is embarrassingly large, and collaboration with other organizations and research associations interested in the study or application of radiation methods is essential if rapid advances are to be made in this exciting new field.

THE MINISTRY OF AGRICULTURE, FISHERIES AND FOOD

WILSON REPORT

IN December 1954 an independent Committee, that is, not an inter-departmental one, was set up to review the ex-Headquarters organization of the Ministry of Agriculture and Fisheries, to which has now been added the remnants of the Ministry of Food, making it the M.A.F.F. The report of this Committee has recently been published* and, from the name of its chairman, Sir Ayrton Wilson, is being referred to as the Wilson Report. Anyone desirous of forming a clear view of the multitudinous activities of this Ministry and how they impinge on the farmer cannot do better than read this report. Although conforming to the usual style of such reports, with short numbered paragraphs, it is extremely lucid and readable and displays throughout its hundred pages the extreme thoroughness with which the members of the Committee have carried out their difficult task.

The Committee was asked "to consider generally whether the organization is best adapted to secure efficient and economical performance of the functions of the Ministry", to which the Committee's reply is summarized as, "It could certainly be better adapted"; whether "there was undue complexity, over-specialization, or overlapping", to which the reply is, "Yes! there is"; and whether "there was duplication and unnecessary interference with the work of local authorities", to which the reply is, "Little or no evidence of this". In addition to these three questions, the Committee was asked to survey the remaining organizations of the Ministry of Food and also to examine carefully the methods for dealing with the acquisition, management and disposal of land by the Minister and with the preparation of cases for consideration under the Agricultural Act of 1947 and the Agricultural Holdings Act of 1948. Because these cases impinge so directly on the rights and livelihood of individual citizens, the Minister evidently felt it necessary, in view of public criticism, to have existing procedures reviewed by an independent body. Comparatively minor improvements are put forward.

The report concludes with no less than seventy-eight main recommendations which, if put into effect, would result in savings approaching a thousand in staff and £1,000,000 in salaries, travelling expenses and general overheads. There would be additional savings on premises difficult to estimate accurately in advance. With the present Government committed to some reduction in national expenditure, it is evident that many of the recommendations of the Wilson Committee are likely to be implemented and they are now being considered by the County Agricultural Executive Committees as well as by the organizations concerned. Clearly it is not possible here to give an adequate summary of the voluminous report and its many findings; but an attempt will be made to select some of the major points.

Apart from its headquarters staff, the Ministry has no less than thirty-two organizations which can be divided into six major groups, with a staff of 8,500, and twenty-six smaller groups with about 1,500. The total annual cost is just under £10 million. The major groups are the County Agricultural Executive Committees, the National Agricultural Advisory Service, the Agricultural Land Service, the State Veterinary Service, Fatstock-Marketing, and the National Milk Testing Service. Examples of the minor groups are the Agricultural Lime Department, Land Drainage and Water Supply, the Rodent Inspectorate and the Insect Inspectorate. The organizations work within twenty-two different sets of boundaries—a fact which, in itself, indicates the probability of frequent lack of co-ordination.

Before planning some pruning, streamlining and regrouping of these numerous bodies the Committee first pointed to certain weaknesses, abnormalities and dangerous tendencies, and then laid down some desirable principles. Unlike most government departments, the Ministry of Agriculture and Fisheries has created its own local authority in the form of the County Agricultural Executive Committees and invested them with both advisory and executive duties. For the executive work, the Ministry has made much use of technical and professional staff instead of keeping to the usual practice of using administrative staff. The numerous separate organizations had the dangerous tendency of getting away from team-work altogether. "The Ministry's local organization is riddled with divided loyalties and dual control." The basic principles which, in the opinion of the Committee, ought to be followed are: first, the operations and methods of a Ministry should be supported by a broad body of public consent; second, that clear ("clean" is printed in the report) lines of command should flow from the centre to the farthest out-station, leaving no officer in doubt about his responsibilities or about who is his superior officer; third, the insidious growth of "perfectionism" must be avoided, for example, the tendency to develop a function beyond reasonable limits and regardless of cost; fourth, the organization and procedure must permit effective control of finance —not merely precise audit but provision for thorough preview of proposed outlay.

---

* Report of the Committee appointed to review the Provincial and Local Organization and Procedures of the Ministry of Agriculture, Fisheries and Food. Pp. vi+108. (Cmd. 9732.) (London: H.M. Stationery Office, 1956.) 4*s.* 6*d.* net.

The most important local body is the County Agricultural Executive Committee, particularly as the National Agricultural Advisory Service county staff is closely associated with it. The proposals of the Wilson Committee regarding the County Agricultural Executive Committees can be taken as illustrative of the lines along which reorganization is envisaged. At the time of the Ryan Committee set up in 1949 with somewhat similar terms of reference, four of the main jobs of the County Agricultural Executive Committees were their responsibility for production targets, conduct of the Farm Survey, supervision of backward farmers, administration of trading services and subsidies. Since then, however, targets have gone, the survey has practically ceased, supervision cases are trivial in number; on the other hand, the country has continued to pay large sums in grants and subsidies. It is clear, therefore, that there must now be concentration on technical development to ensure higher and higher efficiency if the subsidies are to be justified. Technical development must in future be the first and primary duty of the County Agricultural Executive Committees, working in close co-operation with the National Agricultural Advisory Service. A second function would be to act as local adviser to the Minister.

Where State action affects the liberty and livelihood of the individual farmer, there is also need for local consideration of appeals against decisions of Civil servants dealing with routine work such as grants and subsidies. Other local problems, such as the completion of rabbit clearance and the use of land for particular purposes, can be dealt with by the same body. The Wilson Committee accordingly recommends that the future structure of a County Agricultural Executive Committee should be a Main Committee to concentrate on technical work and advice to the Minister, but delegating the other functions mentioned to a tributary body called the Executive Panel. The delegation of duties should be complete, the Main Committee merely receiving a regular report from the Panel. The word 'Executive' would in future be omitted from the name of the County Committee so that it would become the County Agricultural Committee. The chairmen of these Committees, preferably younger men than at present and with a broad outlook and constructive ideas, would meet regularly in the different regions and also have close links with the Minister through liaison officers. With a few exceptions, such as East and West Suffolk which would probably be made into one unit, the County Agricultural Committees would remain on the present county basis.

The report next deals with the routine executive and trading work no longer to be done by the County Agricultural Committee. For these the unit of area suggested is again the administrative county, except that there would be more amalgamations of smaller counties, for example, combining Cumberland with Westmorland, and Bedfordshire with Hertfordshire. In this way the existing sixty county units would be reduced to not more than forty, each with its "Divisional Executive Office". Besides doing the routine work mentioned, the Divisional Executive Office would provide clerical staff for the County Agricultural Committee and have attached to it the Area Milk Organization, the Lime Inspectorate, Pest Officers, etc. The office would be under the control of a senior member of the Civil Service Executive Class. The executive divisions (= counties or amalgamated small counties) would be grouped into Regions with boundaries, for the most part, coinciding with the present Standard Government Regions. In the north and in the south-east, combinations of two regions would reduce the ten Government Regions to eight Agricultural Regions. Wherever possible, the Ministry's Regional Staff would be centred in the standard regional "capital", such as Cambridge. Here there would be in command an administrative, not a technical, officer with the rank of Assistant Secretary. He would be the Ministry's chief official and representative in the region, and would supervise all regional staff comprising twelve separate services such as the National Agricultural Advisory Service, Fatstock Marketing, Defence. The technical staff at regional level, though under the general direction of the Controller, would retain the right of direct access to their superiors at the Ministry on technical matters.

Regarding the twelve services at the regional centre (four of them at county-level also), numerous recommendations are made, some of considerable importance. The National Agricultural Advisory Service would have lost most of, but not quite all, its non-advisory functions. It is also proposed that it should hand over to the Veterinary Service its Milk Production Officers who, "for all practical purposes are not advisory officers nor does the present nature of their work require them to be milk production specialists—they are scarcely concerned until the milk is in the pail". The number of Farm Machinery Specialists is also thought excessive and it is recommended that there should be one at each regional centre and one in large arable counties. In the case of horticulture, the recommendation is that the regional specialists should be reduced in number and sent to front-line work in the counties, where they should be able to do more effective advisory work. The Wilson Committee very pertinently and rightly directs attention to an outstanding weakness of the National Agricultural Advisory Service's structure (which some, including the present writer, pointed out even before it had started to function), that the 'key' man of the service, the District Officer, could only get promotion by "being withdrawn from front line work". An important addition to the Service is recommended owing to the proposed reorganization of the present Agricultural Land Service: it is that a specialist estate management section should be formed at regional level. The land service, it is suggested, should shed its extraneous non-professional duties and become a compact body of highly qualified land agents. Its local organization would be based on the new divisions and obtain its clerical staffs and common services from the Divisional Executive Offices. A somewhat similar reorganization is proposed for the Veterinary Services.

A long chapter of the report deals with "Milk Administration". "We have found it fascinating but extremely complicated." The main recommendation is that the National Milk Testing Service with its 350 staff should be disbanded and its work handed over to the Milk Marketing Board and the Veterinary Inspectorate. It was always difficult to see any real justification for the existence of the National Milk Testing Service.

In conclusion, one feature of the reorganization planned by the Wilson Committee may be pointed out which will please those who, like the writer, continue to maintain that the advisory and educational services should never have been divorced and should be 'remarried' as soon as possible. The County Agricultural Committees will remain based, in general, on existing counties and will have, as their chief concern, technical development and advisory work. It would be a small and comparatively easy step to add to these duties the responsibility for agricultural education in the counties. A great accession of strength would accrue to both services and further large economies in man-power and expenditure could be achieved together with greatly increased efficiency.

H. W. Gardner

STRUCTURE OF VITAMIN B_{12}

By Dr. DOROTHY CROWFOOT HODGKIN, F.R.S., JENNIFER KAMPER, MAUREEN MACKAY and JENNY PICKWORTH

Oxford

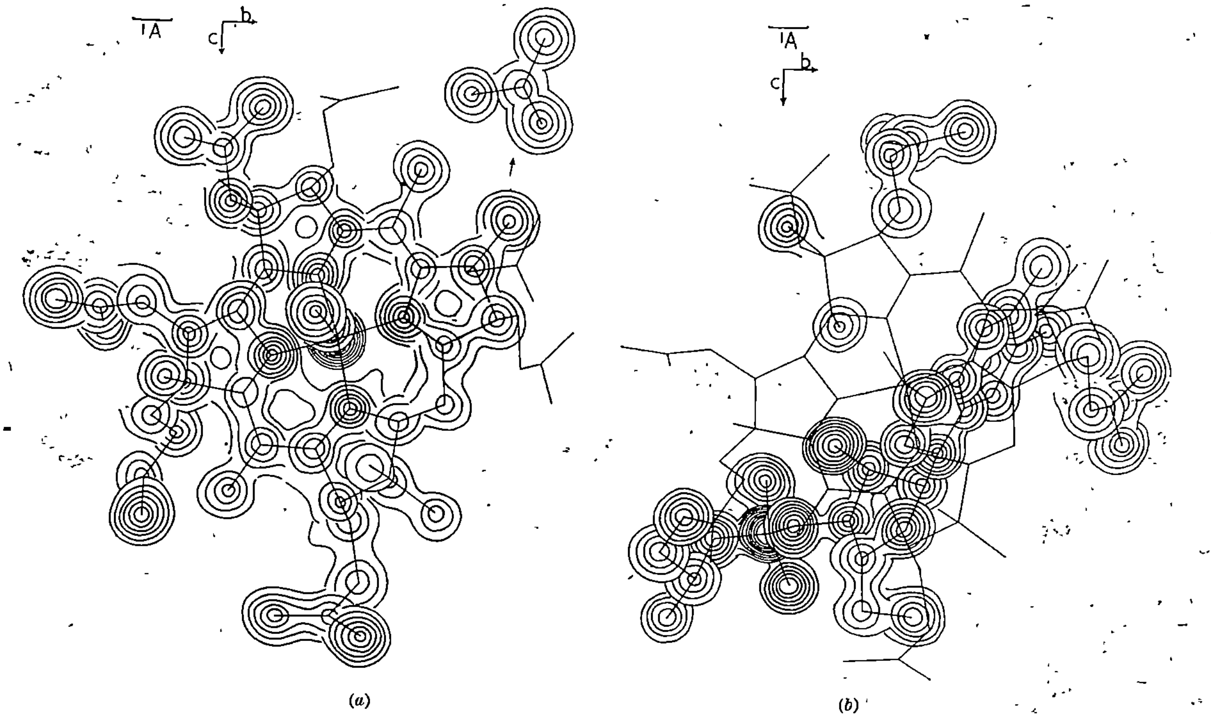
KENNETH N. TRUEBLOOD
Los Angeles

AND

JOHN G. WHITE
Princeton

Since our communication in August 1955[1], we have carried our refinement of the structure of vitamin B_{12} a critical stage further. Four more calculations of the electron density distribution have been made, one for the wet B_{12} crystals, two for air-dried B_{12} crystals and one for the hexacarboxylic acid.

In Fig. 1 are shown the electron density peaks over all the atoms of the B_{12} molecule as it appears from our present calculations in the wet crystals. These peaks are rather lower than those observed for the hexacarboxylic acid owing to the smaller number of X-ray reflexions given by the larger molecule in proportion to its size. But they serve to show the relative positions of all the atoms in space of this very complex molecule within probably as little as 0·3 A. Similar evidence has been obtained for air-dried B_{12}; for both crystals the reliability indices in the latest structure factor calculations, 36·1 and 30·6 per cent, respectively, are now low



(a) (b)

Fig. 1. Electron density-levels from the three-dimensional electron density-distribution for wet B_{12} crystals, calculated with terms phased on 93 atoms

Here, and in Fig. 4, the contours are drawn in the sections of the calculated distribution parallel with the *a* plane, passing at or near the atomic positions. Owing to the complexity of the molecule, complete contours for every atom are not given and the figure is divided into two parts. (*a*) shows the cobalt-containing nucleus and cyanide group; (*b*) the benziminazole, sugar, phosphate and propanolamine groups, the side chains being divided between the two. The acetamide chain on ring *B* is inset. The contour interval is 1 e/A^3.

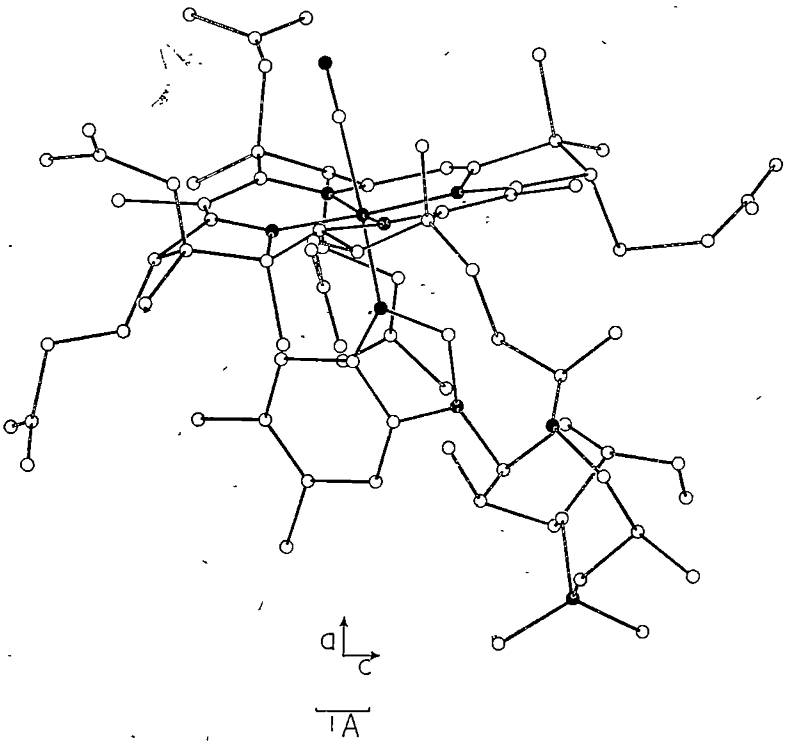


Fig. 2. The atomic positions found in the molecule of vitamin B_{12}. These are shown as derived in the wet crystals, projected on the *b* plane. To distinguish different parts of the molecule, bonds within the cobalt containing nucleus, benziminazole and cyanide groups are shown in black, together with the cobalt and phosphorus atoms and the nitrogen atoms of the nucleus, benziminazole, propanolamine and cyanide groups

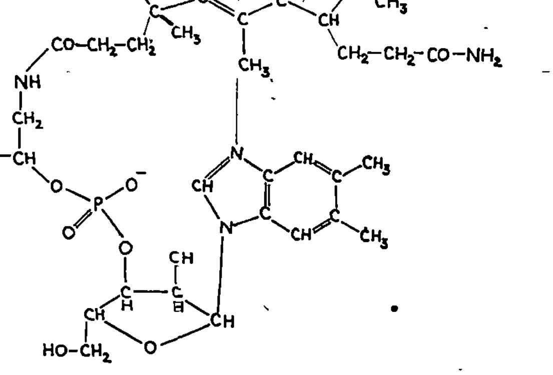
enough to indicate that the solution we have reached is likely to be essentially correct.

The molecule that appears is very beautifully composed, not far from spherical in form, with all the more chemically reactive groups on its surface. It is drawn in projection in Fig. 2. It is built around the two planes of the benziminazole nucleus and the central cobalt-containing nucleus, which are nearly at right angles to each other. The ribose ring turns in a position nearly normal to the benziminazole group, which permits its easy linking through the phosphate, propanolamine, and propionic acid residues to ring *D* of the planar group. The benziminazole nucleus is packed in on either side by the propionamide side-chains in the extended, staggered configuration, attached to rings *A* and *B*; the side-chain on ring *C*, in the gauche configuration, lies above the ribose ring. All the acetamide residues project from the opposite side of the nucleus to the propionamide residues, towards the cyanide group. It is an interesting point that one of them—that on ring *B*—swings round the carbon–carbon single bond from a position directed away from, to one in contact with, the cyanide group, when the crystals are removed from their mother liquor; this permits the rather closer packing of the molecules found in the air-dried crystals. Throughout the molecule, as shown by Figs. 1 and 2, the atomic positions found conform in a most convincing way with the stereochemical rules established by the study of simpler molecules.

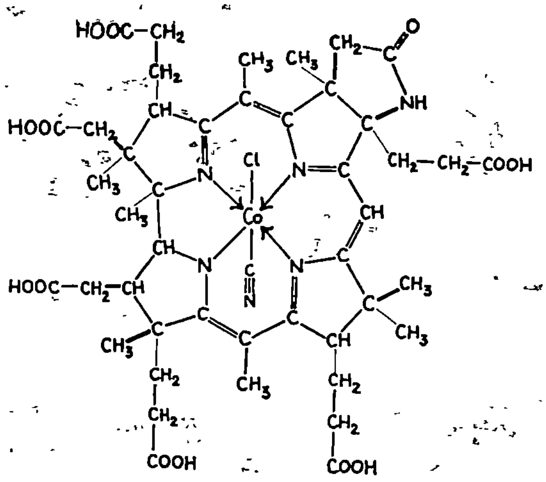
It now seems reasonably certain that we should formulate vitamin B_{12}, $C_{63}H_{88}O_{14}N_{14}PCo$, as in I, and the hexacarboxylic acid as in II, with six double bonds in the inner ring of the central nucleus; these can form a resonating system by intervention of the cobalt atom as illustrated by III. Some evidence in support of this has been obtained by theoretical calculations[2], by spectroscopic measurements[3] and from further chemical studies[4]. Our own evidence for this formulation is the geometrical form of the nucleus, which is illustrated by Fig. 3, and which is closely similar in all three crystals studied. The interatomic distances shown in this figure are derived from the latest calculations on the hexacarboxylic acid and are not individually very precise; in other parts of the molecule distances differing by as much as 0·16 A. from accepted bond-lengths have been found. But it is notable that in the region N_6–N_{18} *all* the bond-lengths are shorter than normal single bond distances; their average value, 1·36 A., is similar to that found in the phthalocyanines[5]. The positions of C_{29} and C_{30}, one or other of which would be expected to be out of the plane of the central ring system if only five double bonds were present, are even more significant. In the hexacarboxylic acid they appeared at all stages of the refinement to be within 0·2 A. of this plane, but in the B_{12} crystals themselves their positions were at first more confused, particularly C_{29}. As a critical test, accordingly, this atom was omitted from the phasing calculations used for the latest electron distribution calculated for air-dried B_{12}. It has now appeared, as Fig. 4 shows, as a small but clearly defined peak at a site which is closely equivalent to that found in the hexacarboxylic



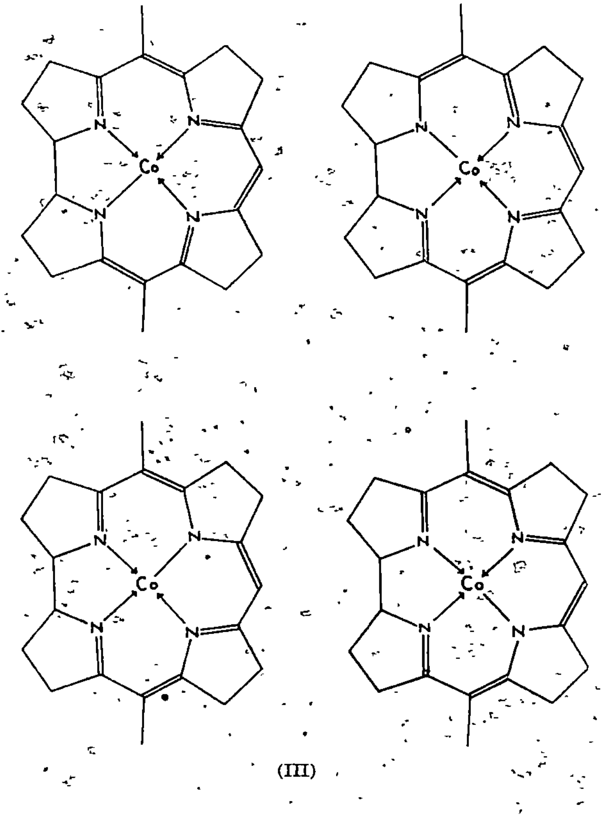
(I)

acid along the line Co to C_8. There is still some departure from planar character in this region of the inner nucleus in both wet and air-dried crystals, but this seems to affect N_{10}, C_9 and C_8 as much as C_{29}. If real, it may be a consequence of a small amount of compression from the benziminazole nucleus, which is in contact with these atoms. It is, in any event, not of the geometrical form that would be expected if C_8 were reduced.

The crystal structures of the different B_{12} compounds are still not completely solved; many of the water molecules which occupy space between the vitamin molecules have been placed, but not all. Still further small adjustments are to be expected on continued refinement of the atomic positions observed. We hope that future calculations will add still greater precision and certainty to our knowledge of the structure of the molecule.



(II)



(III)

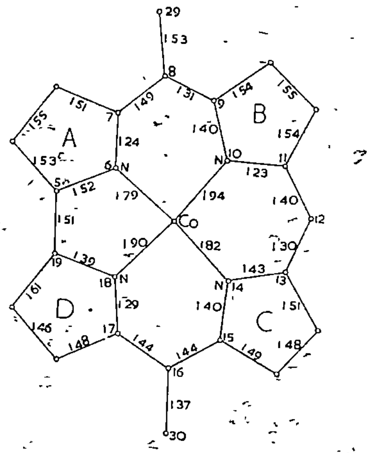


Fig. 3. Interatomic distances found in the inner nucleus of the hexacarboxylic acid, derived from nine refinements of the calculated electron density distribution

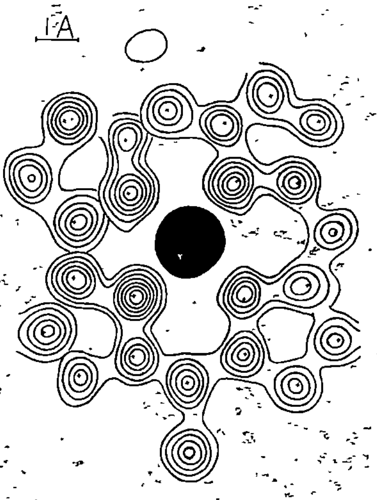

Fig. 4. Electron density peaks over the nucleus in air-dried vitamin B_{12}, derived from the three-dimensional electron density distribution calculated with terms phased on 95 atoms (Princeton data)

The latest series of calculations on wet B_{12} were carried out on the University of Manchester electronic computer through the generous co-operation of Dr. D. W. J. Cruickshank, Miss Diana Pilling and Mr. J. F. P. Donavan, of the University of Leeds. Those on air-dried B_{12} and on the hexacarboxylic acid were made on the National Bureau of Standards automatic computer in Los Angeles, supported by the United States Office of Naval Research.

Again we acknowledge the very generous support given this research by the Nuffield Foundation, and materials and help given us by Dr. E. Lester Smith, Glaxo Laboratories, Ltd., and Dr. K. Folkers, Merck Laboratories. Two of us (J. P. and J. K.) received grants from the Department of Scientific and Industrial Research.

OBITUARIES

Prof. George Sarton

It has been my privilege to enjoy the friendship of George Sarton for forty-three years. He was, in my judgment, one of the great teachers of our age. This was not because he was in the ordinary sense eminent in science, nor because he was an acute investigator, nor on account of anything startlingly original in his outlook. It was because he was a superb organizer of knowledge and an unrivalled integrator, and because these powers came to him with an extraordinary devotion to learning, a uniquely clear vision of its object, an Olympian firmness of purpose, and a quite exceptional industry and linguistic equipment. For about the last twenty years of his life, he was one of the most widely learned scholars in the world. Though he long held a post as historian of science at the Carnegie Institution and a chair of the history of science at Harvard University for many years and was a good, clear, allusive lecturer, he was not a great academic success in the sense of attracting a large following of students. He was, nevertheless, one of the most important intellectual influences of our time, for he defined, illustrated and developed as a new discipline the study of the history, principles and method of science. This he called 'The New Humanism'. The title is not ideal, but it denotes an approach that bids fair, in the New World at least, largely to displace the old humanism.

Apart from the width and depth of his learning, his literary output was very impressive both for its bulk and quality. He edited and largely contributed to fifty-five solid volumes of the journals that he founded—*Isis* and *Osiris*. Many of these volumes contain an introduction by himself which I am tempted to call a sermon. These provide a body of moral and scientific philosophy. It would be worth while putting together the best of them, for they would form a good guide to anyone proposing to devote his life to scientific research. No one can write on ancient or medieval science without often consulting the five enormous volumes of Sarton's monumental and mistitled "Introduction to the History of Science". Its title is wrong because it has become more a court of appeal than an introduction and is seldom consulted in vain. He was the author of many other works, but his great "History of Science", which was to be the crown of his old age, is alas! a torso. He produced the first volume, which is on the science of the Ancient Empires—not the period on which he was strongest—and the second volume is in the press. The remaining half-dozen will never see the light.

Sarton was a very human figure with a Gallic wit, a not unpleasant sense of his own greatness, and a few foibles. Among the latter was an odd aversion to Plato and an incapacity—which grew on him with the years—for writing without adding notes to his text. Even his reviews had notes, and even notes to the notes. But he was always a good, clear and simple writer and one may search many pages of his innumerable works without finding an obscure passage.

His linguistic attainments were astonishing. He was brought up trilingual—French, Flemish and German. He had a good classical education and graduated in the physical and mathematical sciences in his native Belgium. He married an English lady in 1912 and before settling in the United States acquired fluent and perfect English which was, however, never quite freed from a delightful Gallic tang. He could use all the major European languages freely and obtained facility in Hebrew and Arabic. He knew some Chinese and was led to its study by something more than an inkling of the great technological and scientific treasures in that language that are now being unearthed by Dr. Joseph Needham. To all the vast stores of learning that these accomplishments imply, he added a very wide knowledge of modern science. In his later years he had become particularly attracted by biology and, though without early training in that department, it is remarkable how much he wrote on it and how seldom he stumbled for lack of understanding. He was a master of those who know, and it is therefore not entirely fanciful to compare him to his own master, Aristotle.

What influence did Sarton exert on our age? I can only put the matter as it appears to me. Among 'humanists' surprisingly little, and in Great Britain scarcely any at all. By most English students of the classical, literary and historical disciplines in Britain his massive works are, I imagine, scarcely ever consulted and remain almost unknown. In the United States he had become something of a national figure, and there, even among humanists, his influence was certainly greater. This partial eclipse of his genius is, I believe, temporary. On both sides of the Atlantic the overwhelming need for scientific and technological training and the corresponding earlier specialization is producing a novel situation. A new humanism is needed, and several universities in England and a larger number in the United States have instituted departments of the philosophy and history of science. In these the work of Sarton is given a place accorded to that of no other man, and his influence in all that concerns the humanization of science is bound to increase in the near future.

Lastly, what were the intellectual influences that were instrumental in moulding Sarton's own thought? There can be no doubt that, of those who lived into the twentieth century, Tannery and Duhem affected him most deeply. More distantly he was evidently a follower of August Comte, and his greatest works bear the authentic Comtian mould. He accomplished the task which Comte suggested. The key to Sarton's thought is that true knowledge is a unity and that to divide it into categories—scientific, literary, religious, æsthetic, etc.—for any but practical purposes, is to mistake its nature.

All his work was helped by a serenely happy domestic life. Sarton died in April of this year at the age of seventy-two. Mrs. Sarton—who was an artist in her own right—died some years ago. He is survived by a daughter, May Sarton, a distinguished novelist and poet.

CHARLES SINGER

Dr. G. Liebmann

GERHARD LIEBMANN, who died suddenly on June 18, was born on June 29, 1906, in Berlin. In 1925, he matriculated at the Falk Realgymnasium, Berlin, and proceeded to read physics in the University of Berlin under such teachers as Planck, Von Laue, Schrödinger, Wehnelt and Nernst. He graduated with honours in 1928. Continuing as a postgraduate research student, he was awarded his doctorate of philosophy in 1930. Following this, he was awarded a German national research fellowship in physics which he served under Prof. Nernst, at the same time assisting Prof. Wehnelt as demonstrator. After six further years research in German industrial laboratories, he came to Britain because of the adverse conditions in Germany under the Nazis in 1936. Shortly after his arrival in Britain, he was appointed chief physicist and head of the Vacuum Physics Section of Cathodeon, Ltd., in Cambridge, where he served until 1947, when he took a senior appointment in the Research Laboratory of the Associated Electrical Industries, Ltd., at Aldermaston in Berkshire.

His earlier researches in Germany were concerned with high-temperature physics, infra-red spectra and electronic valves. In Great Britain, he made important contributions in the development of television cathode-ray tubes, valves and image converters. He became interested in the electron microscope while in Cambridge, and built an instrument there.

Already he had published many papers, and taken out more than forty patents. He later developed his interest in the electron microscope, and put to good use his innate mathematical ability and ingenuity. His development of the resistance-network analogue calculating method, and his use of this in calculating the properties of electron lenses, contributed largely towards the development of greatly improved electron microscopes. His scientific papers were then appearing in many scientific journals, and were being read in European countries, in the United States and in Britain. He latterly extended his reputation in the computational field by the development of resistance-network analogue methods for the solution of the transient heat flow equations, fourth-order differential equations, and the more complicated equations occurring in thermal stress and neutron diffusion problems. He lectured by invitation in the United States in 1955, and in Brussels early in 1956, and was appointed vice-chairman of the International Analogue Computation Association. He had long been a Fellow of the Institute of Physics, and several times lectured at the Institute, and was a member of the American Institute of Radio Engineers.

Liebmann was a kindly and loyal man. He was a great lover of family, of science, and the mountain peaks. His interest in science was wide, and his advice to colleagues and assistants has contributed greatly to their success. His powers of concentration were great. He was liked and admired by all. His memory will live with his friends because of his understanding and his sincerity, with his colleagues because of his example and guidance, and with his fellow scientists because of his scientific achievements.

He leaves a widow, a son and a daughter.

M. E. HAINE

NEWS and VIEWS

Chancellorship of the Massachusetts Institute of Technology: Dr. J. A. Stratton

A NEW post, that of chancellor, has been established at the Massachusetts Institute of Technology, and Dr. Julius A. Stratton, at present vice-president and provost, has been appointed as the first holder. As chancellor, Dr. Stratton will be directly responsible for administering the academic side, including staff, of the Institute's affairs and will be deputy to the president, Dr. James R. Killian, jun., who is the Institute's chief executive officer; the chancellor will act as president in the latter's absence. The other principal officers of the Institute are Admiral Edward L. Cochrane, vice-president in charge of relations with industry and government, and Mr. Joseph J. Snyder, vice-president and treasurer. Dr. Stratton graduated from the Institute in 1923 and, after study in Grenoble and Toulouse, gained the D.Sc. of the Federal Institute of Technology, Zurich, in 1927. He became assistant professor of electrical engineering in the Massachusetts Institute in 1928 and then assistant professor of physics (1930), associate professor of physics (1935) and professor of physics (1941). He was on the staff of the Radiation Laboratory at the Institute from its inception in 1940 until the end of the Second World War. During the War he was at first engaged on communication surveys and other problems over the North Atlantic and in North Africa and Italy; later he advised on problems of ground radar, radar fire control and radar bombing, and assisted in the establishment of aids for all-weather flying. For these services he was awarded the Medal for Merit. After the War Dr. Stratton became director of the Research Laboratory of Electronics at the Institute, the peace-time successor to the Radiation Laboratory. He was made provost of the Institute in 1939, with the primary responsibility for co-ordinating inter-school educational and research facilities, and two years later he became vice-president as well.

Mechanical Engineering at Swansea: Prof. R. H. Macmillan

MR. R. H. MACMILLAN has been appointed to the newly created chair of mechanical engineering at the University College of Swansea. Mr. Macmillan, who has been on the staff of the Department of Engineering at Cambridge for the past ten years, was educated at Felsted School and Emmanuel College, Cambridge, where he took the Mechanical Sciences Tripos in 1941. He was then commissioned in the Technical Branch of the R.A.F., where he was concerned mainly with automatic equipment for gunsights and with rockets. Since returning to Cambridge, he has published several papers on problems of automatic control, and his textbook, "An Introduction to the Theory of Control", first appeared in 1951. He spent the academic year of 1950–51 working as a visiting assistant professor in the Mechanical Engineering Department of the Massachusetts Institute of Technology, and on a later visit to the United States contributed to the Frequency Response Symposium of the American Society of Mechanical Engineers: on this occasion he also lectured on aspects of automatic control at the Universities of Pennsylvania and Minnesota. Mr. Macmillan's particular interest is in explaining engineering developments to other scientists and to the general public, and in considering their social implications; in this connexion the B.B.C. has broadcast a number of his talks, and last autumn he gave a popular series of afternoon lectures at the Royal Institution. His book, "Automation: Friend or Foe", has just been published by the Cambridge University Press.

Royal Society and Nuffield Foundation Commonwealth Bursaries

AWARDS under the Royal Society and Nuffield Foundation Commonwealth Bursaries Scheme have been made as follows: A. B. Acton, assistant lecturer in genetics, University of Glasgow, to work in Toronto on the comparison of the chromosome conditions of Canadian populations of Chironomid flies with those in Britain (July–September 1956); Dr. W. R. Adey, senior lecturer in anatomy in the University of Melbourne, to visit neurological centres in Great Britain in order to extend his studies on temporal lobe epilepsy (December 1956–February 1957); Dr. L. Davies, lecturer in zoology, Durham Colleges in the University of Durham, to study blackflies and other biting insects, at Ottawa and Hamilton, Ontario (July 1956 for three months); J. Harley-Mason, lecturer in chemistry in the University of Cambridge, to investigate in Jamaica some West Indian plant products of potential chemical and medicinal interest (December 1956–April 1957); Dr. N. E. Hickin, of Leatherhead, Surrey, to visit Uganda during October 1956 to collect material for continuation of his studies of caddis flies (October 1956); Dr. A. Mohiuddin, reader in zoology in the University of Karachi, to study parasitic protozoa at the London School of Hygiene and Tropical Medicine (September 1956 for about twelve months); Dr. R. P. Rastogi, lecturer in chemistry in the University of Lucknow, to study at Reading and Edinburgh thermodynamic properties of mixtures (July 1956 for twelve months); Dr. W. M. Smith, associate professor of chemistry in Queen's University, Kingston, Ontario, to study at Oxford the kinetics of reactions in the liquid phase, with particular emphasis on fast reactions and the influence of the solvent (July 1956–June 1957); Prof. H. Waring, professor of zoology in the University of Western Australia, to investigate at Cardiff the influence of melanophore hormone preparations on carbohydrate metabolism, and particularly on the hyperglycæmia induced by adrenaline (October 1956–January 1957).

Ramsay Memorial Fellowships: Awards

THE Ramsay Memorial Fellowships Trustees have made the following awards for 1956–57: Dr. M. J. Stephen, a general fellowship at the University of Oxford; a Glasgow fellowship to Mr. G. S. Harris, at the University of Cambridge; a Canadian fellowship to Mr. A. H. Webster, at the University of Cambridge; a Netherlands fellowship to Dr. C. H. Stam, at the University of Leeds; and a United States fellowship to Mr. P. B. Sherry, at the University of Oxford. The Trustees have renewed the following fellowships for 1956–57: Mr. B. R. Hammond (general fellowship) at the National Institute for Research in Dairying, Reading; Mr. E. Haslam (general fellowship) at the University of Cambridge; Mr. H. Inokuchi (Japanese fellowship) at the University of Nottingham; Dr. R. Vicente and Mr. F. Garcia-Moliner (Spanish fellowships) at the University of Cambridge.

New Veterinary Building at Cambridge

A NEW building to house the Veterinary Investigation Officer and his staff of the Ministry of Agriculture, Fisheries and Food is to be constructed on the site of the School of Veterinary Medicine of the University of Cambridge. This was only made possible as a result of a gift of £10,000 by Lady Brigid von Preussen and her husband towards the cost of the scheme. The Veterinary Investigation Officer is responsible for investigating outbreaks of diseases among herds and flocks of the eastern counties of England. A great deal of clinical and pathological material is continually being sent to the centre for diagnostic purposes, and pressure of routine work not infrequently prevents the fullest use being made of this valuable material for research purposes. It was considered that contiguity of the centre with the School would help to overcome this and would facilitate collaborative research between the clinicians and pathologists of the School, on one hand, and with the veterinary staff of the Ministry's centre, on the other. Besides the value of the pathological material for teaching purposes, the student will inevitably be more likely to be introduced to the herd and flock problems of the surrounding counties by being continually brought into contact with the work of the Ministry's veterinary officers.

Westonbirt Arboretum

THE Forestry Commissioners have appointed the following as members of the Westonbirt Arboretum Advisory Committee: The Hon. L. Palmer (*chairman*), Sir Edward Salisbury, Sir Harry Champion, Mr. C. M. Floyd, The Duke of Beaufort, Sir Eric Savill, Prof. E. W. Yemm, Mr. Hiram Winterbotham and Mr. J. S. L. Gilmour. This arboretum, with some neighbouring woodland, was acquired recently by the Commissioners. It is situated to the south-west of Tetbury. It covers more than a hundred acres and is a unique collection of trees and shrubs; it was founded in about 1820 by the ancestors of the late Sir George Holford, by whom it was afterwards developed, the work being continued by the late Lord Morley. Oaks, yews and conifers form a background to numerous rare specimens of trees and shrubs collected from many parts of the world, particularly Japan, China and the western States of America, and including, notably, varieties of maple and rhododendron. The Committee will consider means of facilitating public access to the arboretum.

U.S. National Science Board

ON May 25 the United States Senate confirmed President Eisenhower's nomination of the following as members of the National Science Board of the U.S. National Science Foundation. Drs. L. M. Gould, P. M. Gross, G. D. Humphrey and F. A. Middlebush are charter members of the Board and have been re-appointed. Dr. Warren Weaver, of the Rockefeller Foundation, has been appointed to succeed the late Rev. J. B. Macelwane, and he will retire in 1960. The following have been appointed to serve a term of six years: Prof. E. J. McShane, professor of mathematics in the University of Virginia; Prof. S. M. Nabrit, professor of zoology, Atlanta University; Dr. J. A. Stratton, chancellor, Massachusetts Institute of Technology; Prof. E. L. Tatum, professor of biology, Stanford University.

Paris Academy of Sciences: Elections

THE following have been elected *correspondants* for the Botany Section of the Paris Academy of Sciences: Prof. P. Martens, professor of palæobotany in the University of Louvain, in succession to Prof. E. Gäumann, recently elected a foreign associate of the Academy; and Prof. A. Fernandes, professor of botany in the University of Coimbra, in succession to the late Prof. E. D. Merrill. The following have been elected *correspondants* for the Zoology Section of the Academy: Prof. U. d'Ancona, professor of zoology in the University of Padua, in succession to Prof. D. Keilin, recently elected a foreign associate of the Academy; and Prof. P. Brien, professor of zoology in the University of Brussels, in succession to Prof. A. Vandel, recently elected a non-resident member of the Academy.

Recent Economies in Government Expenditure

THE Chancellor of the Exchequer, Mr. H. Macmillan, made a statement about economies in government expenditure on June 26, in which he said that the estimated savings in defence (£36·5 million on the defence programme and £14 million on defence expenditure) do not reflect any change in the size or shape of the Armed Services and that any major decisions in this field would only be taken after consultation with Britain's allies. The savings of £25·5 million on other Civil Estimates, details of which are given in a paper afterwards circulated, include £810,000 in grants for Colonial development and welfare, including research, £70,000 in economies in capital expenditure by the Agricultural Research Council, £53,000 in economies in training and research and reduction in purchases of equipment by the Forestry Commission, £180,000 in economies in maintenance expenditure on roads and £150,000 in general economy by the Department of Scientific and Industrial Research. Economies of £265,000 by the Ministry of Housing and Local Government are to fall in part on National Parks. From the public point of view, it would seem that, where departments have been efficiently run in the past or have been short of adequate resources, the cuts though small will do real, if only marginal, harm.

Factory Inspectorate of Great Britain

REPLYING to questions in the House of Commons on June 26, the Minister of Labour and National Service, Mr. Iain Macleod, said that, of the ninety-six districts of the Factory Inspectorate, thirty-six have no inspectors possessing university degrees in engineering or chemistry and physics, and only eleven have more than one such inspector. For 1939, when there were ninety-two districts, the corresponding figures were twenty-four and twenty-three. Mr. Macleod said that the question of the technical strength of the Inspectorate is the most important matter now before him as a result of the departmental committee's report, and the problems are being considered whether the establishment of inspectors should be increased and whether more technically qualified people are needed.

National Science Foundation Russian Translation Programme

EXPANSION of the U.S. National Science Foundation programme for the translation into English of Russian research literature has recently been made through a grant of 76,500 dollars for this purpose to the American Institute of Physics. The expanded programme will include the *Zhurnal Teknicheskoi Fiziki* (*Journal of Technical Physics*), *Akusticheskii Zhurnal* (*Acoustics Journal*), and physics articles from the *Doklady Akademii Nauk SSSR* (*Proceedings of the USSR Academy of Sciences*). First issues of the translated journals will appear soon. The Foundation and the American Institute of Physics have already successfully collaborated in the publication of *Soviet Physics—JETP*, a bi-monthly translation of *Zhurnal Eksperimental noi i Teoreticheskoi Fiziki* (*Journal of Experimental and Theoretical Physics*), six issues of which have now appeared. In addition to the programme in physics, the Foundation is supporting translations of Russian papers in mathematics and biology; and plans for the fiscal year 1957 include the earth sciences and the engineering sciences. The American Mathematical Society publishes about 1,000 pages annually of Russian work in mathematics, under the title, *American Mathematical Society Translations*. The Foundation has just awarded a small grant to *Biological Abstracts* for the translation and publication of abstracts from the Russian journal, *Referativnyi Zhurnal: Biologiia* (*Abstract Journal: Biology*). During the last half of 1956 some 1,200 abstracts from Russian journals covered by *Referativnyi Zhurnal: Biologiia* will be translated by Consultants Bureau, Inc., of New York and reprinted in *Biological Abstracts*. The abstracts will be drawn from thirty-one primary journals covering a wide range in the field of biology.

Science Museum Collection of Time-Measuring Instruments

THE interest shown in the collection of exhibits at the Science Museum, London, illustrating the measurement of time has called for a third, revised and expanded, edition of the descriptive catalogue of the objects exhibited in the Time Measurement Section of the Museum (pp. 102+10 plates. London: H.M.S.O., 1955; 6*s*. 6*d*. net). The second edition was published in June 1950. Part 1 of the handbook, entitled "Historical Review", which is published separately and which in its third edition was reprinted last in 1952, consists of a brief review of the history of time measurement together with notes on the principles employed in measuring time. Part 2, the "Descriptive Catalogue", contains the substance of the descriptive labels exhibited with the various objects in the Museum. The collection is classified into twelve large groups, which are further divided into sub-groups, and 463 exhibits are listed (compared with 390 in the second edition), together with some eighty other objects not on exhibition. A new section deals with time recorders, that is, instruments which make a printed record of the time of day at which a certain event takes place. Many of the collection of more than seventy sand-glasses, presented to the Museum in 1952 by the Rt. Rev. Abbot Horne, of Downside Abbey, are now included in the Museum exhibition, in addition to several new exhibits in almost every section. The illustrations in the handbook are the same as in the previous edition, but the illustration on the cover has been changed from a reproduction of a sixteenth-century weight-driven domestic clock to that of a 1718 garden sundial. The price is double that of the previous edition.

Rapid Analysis of Silicate Rocks

DURING recent years the United States Geological Survey has been faced with the problem of achieving a greatly increased output of chemical analyses at a time when the demand for analytical chemists much exceeded the supply. To circumvent this impasse, rapid analytical methods have had to be devised. The procedures described in Bulletin 1036-C of the Survey, "Rapid Analysis of Silicate Rocks", by Leonard Shapiro and W. W. Brannock (pp. 56. Washington, D.C.: U.S. Government Printing Office, 1956; 20 cents), provide for the analysis of the thirteen oxides most commonly determined in silicate rocks by simple direct methods which can readily be learned by relatively untrained personnel and which give results several times faster than formerly. Most of the determinations depend upon the use of a spectrophotometer, flame photometer, or automatic photometric titration equipment. The booklet will be welcomed by geologists and mineral chemists with experience of the tedious and time-consuming routine of conventional rock analysis.

Ethnographic and Archæological Survey in Angola

AN ethnographic survey in the Kioko (Bachioko) region of Angola, made by José Redinha, curator of the Dundo Museum, has been published by the Diamond Company of Angola under the title of "Campanha Ethnográfica au Tchiboco (Alto-Tchicapa)" : Pt. 1, "Notas de Viagam" (pp. 175+5 plates) ; Pt. 2, "Aratacoes e Documentacao Gráfica" (pp. 214) (Museu do Dundo, Publicaçoes Culturais No. 19. Lisbon : Companhia de Diamantes de Angola). The first volume contains the itinerary of the expedition, with ethnographic and archæological details on the people and their country. The second volume is a magnificently illustrated catalogue of the objects collected, together with supporting notes on the arts and crafts of the region. This volume, with its wealth of illustrated detail, should be of considerable value to curators of ethnographical museums and to those interested in the comparative study of the material culture of Negro Africa.

University of Sheffield

THE following appointments have been made in the University of Sheffield : J. P. Duncan (lecturer in mechanical engineering in the University of Manchester), professor of mechanical engineering ; Dr. G. Weber, senior lecturer in biochemistry ; Dr. I. C. Browne, lecturer in physics ; Dr. D. J. Harris, lecturer in electrical engineering. The following resignations have been announced : Dr. J. Lewis, lecturer in chemistry ; Mrs. H. G. Knowles, map curator and librarian in the Department of Geography.

The Council of the University has accepted an offer by Boots Pure Drug Co., Ltd., to provide a medical research fellowship of the annual value of £1,000 for a number of years. The London Tin Corporation, Ltd., is providing a research fellowship in metallurgy, which has been awarded to Dr. B. B. Argent. Other research fellowships have been awarded as follows : Owens-Illinois Research Fellowship in glass technology to Dr. N. E. Richards ; Oldham Research Fellowship in mining to A. G. Neill.

The Council has approved a proposal by the Medical Research Council to establish a Unit for Epidemiological Research on Respiratory Diseases (Air Pollution) in the University. The Unit will be under the direction of Dr. J. Pemberton, senior lecturer in social and industrial medicine.

Announcements

MR. G. H. GREENHALGH has been appointed British scientific attaché in Scandinavia, in succession to Mr. R. G. Silversides, who is returning to the headquarters staff of the Department of Scientific and Industrial Research. Mr. Greenhalgh is on loan to the Department from the Atomic Energy Research Establishment, Harwell.

To commemorate the occasion of the diamond jubilee of the *British Journal of Radiology*, the following have been elected to honorary membership of the British Institute of Radiology: Mr. Cuthbert Andrews ; Sir Russell Brain ; Dr. Russell J. Reynolds ; Dr. F. Gordon Spear.

FOUR new appointments have been made to the staff of the U.S. National Science Foundation. Dr. E. E. Litkenhous becomes programme director for engineering sciences ; Dr. Frank K. Edmondson, programme director for astronomy ; Marguerite Risley, professional assistant for the astronomy programme ; and Dr. Robert R. Brown, professional assistant for the physics programme.

THE British Mycological Society will hold its thirtieth annual plant pathology field meeting in the Nottingham district during July 27–28. Visits will be made to the University of Nottingham Department of Agricultural Sciences, at Sutton Bonington, Loughborough, and to the Boots Lenton Experimental Station, Nottingham. Four papers will be read in the Botany Department of the University. Further information can be obtained from Dr. G. J. F. Pugh, Department of Botany, The University, Nottingham.

THE Faraday Society has arranged a general discussion on "The Physical Chemistry of Processes at High Pressures" to be held in the University of Glasgow during September 20–21. After a general introduction by Prof. A. R. Ubbelohde (Imperial College, London), there will be three sessions on the following topics : equations of state, physical properties and thermodynamic transformations ; chemical reactions and transformations at high pressures ; and detonation and other high-temperature phenomena at high pressures. Proofs of papers will be circulated in advance of the meeting. Further information can be obtained from the Secretary of the Society at 6 Gray's Inn Square, London, W.C.1.

THE Teyler's Foundation and the Teyler's Second Society, Haarlem, are offering jointly a prize for an essay on "The absolute relations, on time and space, between actual events, as brought to light by the theory of Einstein, and the interest which the new insight concerning these might have for views in other domains of knowledge". The prize will consist of a gold medal, worth 400 Dutch florins, or, if the recipient prefers it, this amount in cash. The essays may be in Dutch, French, English or German, and must be submitted by January 1, 1957. Further information can be obtained from the Directeuren van Teylers Stichting, Fundatiehuis Damstraat 21, Haarlem, Netherlands.

THE Department of Industrial Engineering of the Loughborough College of Technology is starting, as from September next, a new postgraduate course in industrial engineering. The course will last one year and will cover a wide range of advanced management topics. In addition, some special subjects will be dealt with, including nuclear energy and automation, which will be approached from the technological point of view ; there will also be sessions on men and machines, which will be concerned with the physiological effects of noise, fumes, dust, vibration, etc. The course is suitable for senior personnel from all types and branches of industry. Further information can be obtained from the Head of the Department of Industrial Engineering, Loughborough College of Technology, Loughborough, Leicestershire.

IMPLICATIONS FOR BRITAIN OF DEARER COAL

THE British public have recently been shocked again by a substantial increase in the price of coal. A figure of 8 per cent increase has only to be repeated a few more times and a serious situation in industry may be realized, for coal must remain, in spite of the marked increase in the use of oil in all branches of industry in Britain in recent years, the basis of Britain's economy. The really serious feature of these repeated unfortunate movements in price is the impetus that the rise in the price of coal gives to price- and wage-increases everywhere. Unfortunately, there are economists who believe that a rise in the price of coal is the most effective means of inducing more efficiency in the use of coal. The fallacies of these views when applied to the existing situation are being abundantly shown by the sequence of events that seem to have become a repetitive feature of our present times. They occur in spite of the trend to replace coal by oil because the outlook reveals a possible increase in the shortage of coal occasioned by still greater demands for power in industry if Britain is to maintain her competitive position in world export markets. As a further feature of the trend towards the use of oil, there is the Prime Minister's recent warning of the danger of war that might arise from the need for the maintenance of oil supplies from the Middle East—a sorry picture and prospect for a country whose greatest mineral asset lies in her coal measures.

The *Financial Times*, in a leading article of May 29, directed attention to the fact that the formidable burden that is being forced upon British industry by the impact of dearer fuel, power and transport comes at a time when other raw materials are showing a downward trend in price—copper down 30 per cent from this year's peak, tin 16 per cent, lead and zinc 11 per cent below their 1956 peak and rubber 38 per cent. Wage increases are not in the present case the only cause of the rise in price, for the nettle of the accumulated deficit in the costs of raising coal and costs of the mine reconstruction programme had to be grasped, and the sooner the better. Where lie the remedies ? Technical advances in fuel utilization have in the past contributed in a substantial measure to the advancement of Britain's economy ; but such instruments of progress can only move at the natural rate at which the means in the form of finance and technical personnel become available. Thus the call for more technologists can only meet with response in the course of years, as in the case of the development of the use of atomic energy. Meanwhile, the situation promises to become desperate, bearing the threat of the effect of foreign competition in export markets. At the moment, the only sure sign seems to be that the loss of such markets is going to be the determining factor in the situation.

There does, however, remain one saving grace : the inherent good sense of the British race, and the strange ability to 'muddle through' in times of trouble. Put in more conventional, if less expressive, form, both the industrialist and the working man, when they finally recognize a dangerous situation, have a tactical genius for mastering that situation. They do the job another way to save both heat and energy, and, if necessary, labour. Thus 'automation' to the journalist may be a magic word whereby to scare the uninitiated in a headline ; to the engineer it is mechanization and instrumentation, employing techniques which he has probably been developing for many years. In spite of many statements to the contrary, Britain is as highly skilled in these arts as any other country. In such directions lie the ultimate solutions of our problems of rising costs, aided by the inherent characteristic of refusing to panic, however black the approaching cloud.

R. J. Sarjant

THE FUTURE OF METALLURGY

AT the annual general meeting of the Institution of Metallurgists, held on May 15, Mr. G. L. Bailey, director of the British Non-Ferrous Metals Research Association, was installed as the new president. In his address, Mr. Bailey, after discussing the progress of the Institution, went on to consider the rather distant future of the metallurgical industries.

The vast majority of metals are used for traditional purposes which are neither particularly spectacular nor exciting ; but if, for example, we were compelled to carry on without steel, copper or cast iron, the question of finding suitable substitutes would in many cases be surprisingly difficult. If the demand for a specific metal exceeds the supply, the first thing to happen is a change in what is, somewhat deplorably, known as 'the pattern of use'. In the first place, more readily available metals, such as aluminium, magnesium and, maybe, titanium, would come into more extensive use, and secondly, there would be increasing employment of non-metallic materials for purposes for which metals were previously used. These are matters both of economics and of technical efficiency—if a plastic pipe has advantages over a metal one at the same price, it will be used. If it is not so good but a lot cheaper, it will still be used to some extent. This balance is an ever-changing one as new properties are discovered and new methods of production developed.

This factor, new methods of production, is one of basic importance. In connexion with estimates of known resources, it must be borne in mind that the detailed prospecting of ore body is usually carried out merely to ensure an adequate supply for a specific and limited term of years. As a result of some change of price, of the development of new methods of beneficiation or of extraction process, enabling a poorer grade of ore to be used more efficiently, what may not now be an economic ore body may well become one in the future. Aluminium, for example, is to-day produced from bauxite; but there are immense amounts of aluminium available in clays which could not, however, be used with existing knowledge except at much higher cost.

It is considerations of this kind which make it so difficult to forecast the distant future with that degree of assurance adopted by some people with less knowledge of the metallurgical industries.

Apart from traditional ones, there are emerging a series of spectacular uses of metals which will control the whole of the future development in many fields of engineering. It is yet to be seen how far alloys based on the newer metals can be produced with properties which have hitherto been unobtainable, and a vast, indeed unlimited, field of metallurgical endeavour is thus opened out.

The big competitor with the metals would appear to be the plastics, particularly when suitably reinforced, and in some quarters there is the assumption that these will go on getting better and cheaper, while the metals themselves are becoming increasingly scarce. It is by no means certain that this somewhat superficial view can be justified. Given sufficient energy, imagination and enthusiasm on the part of the metallurgist, the metals, by improving the methods of extraction and fabrication, can also, perhaps, become cheaper; and new alloys of better properties will most assuredly be developed. It is Mr. Bailey's forecast that the future of the use of metals, both for the more spectacular purposes of modern engineering, and for the older, traditional ones, is not only assured but also full of interest and, in places, definitely exciting.

THE IMPACT OF ENGINEERING ON SOCIETY

FOR the second Graham Clark Lecture, delivered to a joint meeting of the Institution of Civil Engineers, the Institution of Mechanical Engineers and the Institution of Electrical Engineers at the Institution of Mechanical Engineers on April 27, Sir Maurice Bowra, vice-chancellor of the University of Oxford, chose to speak on "The Impact of Engineering on Society", pointing out that almost every society of which we know practised engineering to some degree. A considerable degree of civilization can be secured with a minimum of engineering; but a society which does not believe in engineering, or see its possibilities, is, as the failure of the Greek and Roman systems shows, unlikely to survive. Civilization is a sensitive plant, and its first duty is to look after itself. Sir Maurice suggests that the trouble with the Ancient World was that it never had any difficulty in finding men to do tasks which we assume should be done by machines, and the educated and governing classes accordingly never turned their minds to other, and better, ways of getting work done. That the Romans, like the Chinese, rejected machines in the last resort because their ruling classes were snobs is a social fact of first importance, and Sir Maurice proceeds to demonstrate its relevance to modern times, and to show how economic forces played an important part in securing recognition of the idea that machines can do much that men cannot do by themselves and in creating opportunities for the engineer.

This great change, however, has not been revolutionary in the political sense, although it has changed the whole appearance, and even the structure, of society. Engineering is not a political activity; it aims instead at the control and exploitation of natural resources to give a greater degree of human welfare, and it becomes political only when its existence is threatened by authority or when it is taken up by authority for its own sake. Indeed, within the limits of the social frame and national States within which the engineer works, his work has a strong stabilizing influence; and so far as engineers must share the blame for man's failure to evolve means for satisfying his desire for security and prosperity, it is for sins of omission rather than of commission.

In Sir Maurice's opinion, engineers have taken too modest a view of their own task and duties. More than any other branch of human activity, engineering provides an imaginative equivalent to war and has the advantage that it creates instead of destroying. Engineering, however, contributes much towards the drive towards uniformity and the destruction of that rich variety of experience which characterizes the great humanistic tradition; and it is a serious charge that the influence of engineering interferes with the variety of the individual self and shapes it to a uniform mould by imposing on it certain patterns through modern methods of indoctrination such as the press, cinema, wireless and television. Sir Maurice questions, however, whether such means will retain their ability to impose uniformity, and he also finds grounds for hope in the undeniable tendency of men to pursue the specially difficult task of thinking for themselves.

Engineering may in the end make it easier for thought to be free, and, while admitting that engineering tends to impose a standard of culture which lacks the variety and beauty of the old craftsmanship, Sir Maurice also sees no reason why a world that relies on machines more than on handicrafts should not produce objects as satisfying as those of the old craftsmen. Because they will give delight to a far greater number of people, a new kind of grace and charm may emerge, and if men really were to know what are the ends to which he would be able to turn Nature, he should be able to do on an ever extended scale what he has already begun to do with such imagination, devotion and skill.

HEALTH HAZARDS IN THE COAL AND CHEMICAL INDUSTRIES

THE first provincial meeting of the British Occupational Hygiene Society was held in the University Hall, Liverpool, during April 19–20. In his presidential address, Dr. C. G. Warner, dust suppression scientist of the South Western Division of the National Coal Board, spoke of the satisfactory progress of the Society, an indication that by practical activities it is fulfilling its aim of promoting the science of occupational hygiene. Dr. Warner went on to talk about the remarkably changed situation regarding pneumoconiosis in coal mines which has been occasioned, on one hand, by increased awareness of the disease and, on the other, by measures taken for suppressing airborne dust.

South Wales was formerly a bad area, and after 1943, when the legal definition of pneumoconiosis was relaxed, the rate of certification rose to a peak figure of 55·6 men per thousand employed; by 1947 it had fallen to 30·3. Meanwhile, in the rest of

Britain the corresponding figure for 1947 was only 1·9 men certified per 1,000. As knowledge of pneumoconiosis spread, the number of cases reported in other parts of Britain rose from 597 in 1945 to 3,542 in 1954. The rapid improvement in dust control had its effect, however, and the number of cases in South Wales fell from 5,224 in 1945 to 927 in 1954. Many years elapse before the disease can be detected in a coal miner, even when he is working under dusty conditions, and the present victims accumulated most of the dust load in their lungs some time ago. Such conditions are by now almost eliminated, and it is expected that in twenty years time only the mildest type of pneumoconiosis will continue to be encountered.

The first paper at the meeting was read by H. Pirie, of the Technical Service Department, General Chemicals Division, Imperial Chemical Industries, Ltd., his subject being the production and uses of chlorine. Chlorine was formerly transported as bleaching powder ; but, since its use as a war gas in 1915, it has been transported as liquid, and many tens of thousands of tons a year are now handled in tanks, drums and cylinders. Many users, such as waterworks operators or baths superintendents, have no technical experience, and rules have been devised for their protection. The important points are as follows. (1) Liquid chlorine must be dry, and the packages and valves foolproof. Filling ratios must be observed, and containers serviced and tested regularly. (2) The customer should know how to use the product and to handle the packages safely. His drum and tank installations require initial inspection, and instruction and precaution cards are issued. (3) The customer should know what to do in the event of an accident. A chlorine emergency service is available to deal rapidly with trouble at the premises of any user. (4) Regular visits to the customer are made to ensure that the necessary precautions are being taken.

Trichloroethylene is one of the oldest of the commercially available organic compounds of chlorine and the one made on the largest scale. It is less dangerous than many others because it has no chronic effects. It has many uses in industry and can be used safely provided simple precautions are taken.

Mr. Pirie also referred to the system of labels for hazardous products devised by the Association of British Chemical Manufacturers. These are intended to protect the transporters of such substances—railway employees, lorry drivers, storekeepers, etc. They are distinctive and easily recognizable, name the particular hazard, describe its nature, and give simple precautions to be observed in case of spillage, fire or other accident.

The next paper, on the technique of particle measurement in industrial hygiene, was delivered by G. L. Fairs, of the Research Department, General Chemicals Division, Imperial Chemical Industries, Ltd., who described various established methods of taking samples of dust. These included isokinetic sampling downstream of a mixing baffle, sampling in ducts, and the horizontal elutriator for size separation. Cells for sampling mists containing particles liable to change in size by evaporation or condensation were also mentioned.

Dealing with microscopic analysis of samples, Mr. Fairs stated that below 1 micron it is impossible to differentiate between the images of larger particles and diffraction haloes of much smaller ones ; the electron microscope should replace the visual instrument for studying fine dusts. Sedimentation analysis, based on Stokes's law for the rate of fall of particles in liquid, suffers from the disadvantage that samples of the different size fractions remaining in suspension become very attenuated towards the end of the process and their removal creates a disturbance. An apparatus was described which is better in these respects, since it works by flushing out the settled particles for estimation.

Elutriation, by blowing air through a powder to carry away fine particles which settle more slowly than the air speed, enables size fractions to be determined by filtering the effluent and repeating at decreasing rates of flow. It has been found that 30 seconds of blowing is often sufficient to give adequate separation with the powder on a gauze support in a cylindrical elutriator tube.

The final paper was read by Dr. J. D. Paterson, of the Medical Department, General Chemicals Division, Imperial Chemical Industries, Ltd., and dealt with hydrofluoric acid. He said that considering only the acute effects, and ignoring the chronic, this compound must be regarded as even more severe in its action than mustard gas. In designing plant, the possibility of hydrofluoric acid coming into contact with the operators should be reduced to a minimum. In addition, to guard against mischance, adequate protective clothing is provided, means of decontamination are available, and effective medical supervision is at hand.

The acute hazard is associated with concentrations above 20 per cent, which damage body tissues ; acid stronger than 60 per cent causes damage which is immediately apparent. A unique effect with hydrofluoric acid is its power of penetration to a depth where it exerts a dissolving action on cellular membranes, causing liquescent necrosis and decalcification of bone. Pain is very severe and may be immediate or delayed for some hours, according to the strength of the acid. Treatment consists of washing with copious amounts of water followed by a dressing of magnesium oxide paste. This is usually sufficient for mild burns. Injection of 10 per cent calcium gluconate into and around the burned area until there is weal formation relieves more severe cases very rapidly. Dr. Paterson has not found it necessary to give an anaesthetic before injecting. Protective clothing requires careful inspection. The majority of burns are caused by pinholes in gloves which get hard wear.

The chronic hazard is the possibility of fluorosis, which is a condition of sclerosis of bone and, in extreme cases, ossification of the ligaments. Protective clothing, including a fresh-air hood to prevent inhalation of vapour, is an insurance against fluorosis ; but when the hydrofluoric acid plant of Imperial Chemical Industries came into production, a weekly urine test and estimation of fluorine content were established. The risk of fluorosis is slight when the fluorine is below 10 mgm./l. of urine, and the policy of the firm is to take 1 mgm.l. as a safe excretion-rate. It soon became apparent that the excretion-rate of fluorine was so high that daily measurements were necessary to detect peaks. After a time, these observations provided a valuable indication that all was well with the plant, and enabled small defects, which would otherwise have passed unnoticed, to be rectified. In spite of all precautions, the Medical Department still has to treat an occasional hydrofluoric acid burn, usually due to a faulty glove ; but it has never had a serious case, nor a burn of the eye. Dr. Paterson also referred to chlorine and bromine trifluorides, which are very reactive and produce thermal burns in contact with the skin, but do not penetrate in the manner of hydrofluoric acid.

The meeting concluded with a film illustrating the work of the General Chemicals Division of Imperial Chemical Industries, Ltd., and members of the Society were conducted around the Castner–Kellner and Rocksavage Works on the following day.

C. N. DAVIES

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES

ANNUAL CONGRESS IN TUNBRIDGE WELLS

THE South-Eastern Union of Scientific Societies held its sixty-first annual congress in Tunbridge Wells during May 24–27 under the presidency of Dr. W. E. Swinton. The Tunbridge Wells Natural History Society was the host society, and the choice of Tunbridge Wells for this year's meeting was particularly appropriate since the first congress of the Union, on the occasion of its foundation sixty years ago, was held there in April 1896.

At the young naturalists' evening, a panel of experts answered questions ranging from the cause of the glowworm's glow to the evolution of group flying, as with starlings in the autumn. Major Maxwell Knight showed his film of the hand-rearing of the cuckoo.

The Archæology Section was addressed by Major J. M. T. Burchell, his subject being the archæology of the Medway Estuary. He emphasized that geological evidence precluded the possibility of the manufacture of pottery, during Roman times, in the area and said that kilns have not been discovered. The creeks in the marshes were, during that period, used for trading purposes, and the abundance of material found, including the Upchurch ware, can probably be attributed to this source. Major Burchell afterwards conducted the party to Addington to view the work being carried out in the investigation upon a long barrow, where probing for outlying stones and digging to expose them is in progress. A visit was also made to Coldrum, an excavated long barrow, now in the care of the National Trust.

The president of the Zoology Section, Dr. H. R. Hewer, in his address spoke on the importance of keeping field records. He said that the natural sciences are primarily observational rather than experimental, and therefore the facilities of a laboratory and high technical training are not essential. The glory of zoology is, in the main, due to the amateur field naturalist, Darwin and Wallace being examples. The great period of accurate observational work in zoology was from 1850 to 1900, undertaken in an endeavour to determine the ancestry of species. To-day the emphasis is upon ecological studies, where natural observation with statistical correlation is of primary importance. The Zoology Section's excursion was to High Woods and Scotney Castle, by permission of Mrs. Hussey, under the leadership of Dr. L. B. Langmead.

Dr. Swinton chose as the title of his address, "Nature and the Free Mind". He began by pointing out that practical scientists at every level should be concerned with the history of science and should not leave it to the historians and philosophers. The collation and preservation of local records and the need for sharing field problems call for the national provision of finance and apparatus to help these valuable studies. Perhaps the most important role is to contribute to the understanding of the place of science in the community. While there is no need to stress some of the benefits that accrue from the advance of research, there is, at the same time, the undoubted fact that many people believe that science is something inevitable and complete, and that persistence is all that is needed to reveal the whole truth. It is salutary to remember that the rise of science was fortuitous. The ready acceptance of Darwinism may have been the result of the recognition of the power of scientific discovery as revealed in the Great Exhibition of 1851. Science tries to explain itself; but the symbols involved are frequently beyond the intelligibility of the public. The philosophers have maintained that, despite this, science is irrational, although that same public is now the patron of natural science. Yet, unlike religion, philosophy, manners and customs, science is nationally transferable, and the practice of its deleterious forms can be undertaken by backward people. A substantial increase in the numbers of servants, students and practitioners of technical science to enable Great Britain to compete in the world will be aided by an appreciation of the limitations of the various disciplines. The facts of science are neither good nor bad inherently, but are in accordance with their uses in human hands. Much scientific apparatus is limited in its application by the receptive qualities of the human eye, so there are similar limits to human intelligence, perception and morality. One of the major needs in our community is the realization that science is not a juggernaut come to crush its sponsors and creators, and, above all, it is still capable of being moulded into the instrument, not the master, of mankind. Despite discoveries and formulæ, there is still room for the freedom of the mind.

The address to the Botany Section was given by Prof. C. T. Ingold, speaking on "Gasteromycetes, or Nature tries again". He discussed the disparities of numbers in genera and species, saying that, while the numbers of genera of Hymenomycetes and Gasteromycetes differ slightly—170 in the former to 110 in the latter—there is a difference of more than ten to one in the number of species—6,900 Hymenomycetes, 630 Gasteromycetes. He suggested that, upon the evidence of spore distribution, it is probable that the Gasteromycetes have evolved from the Hymenomycetes by a process of degeneration. The members of the Section visited Saxonbury Hill and Ashdown Forest, where the rarer plants present were shown and described by Dr. Francis Rose.

The president of the Geology Section, C. C. Fagg, described the swallow holes in the Mole Gap and their effect upon the river flow and the water supply available over an area of 130 square miles with an average annual rainfall of 30 inches. The water-level is below the river bed, and the table is maintained by seepage rather than by the swallow holes, although there are twenty-nine of these still active, some being on the bare Chalk. Prof. S. W. Wooldridge, speaking on the geomorphology of the Central Weald, urged the reconsideration of the generally accepted theory of the Wealden anticline. He demonstrated that, instead of a simple anticline, there is a complex structure with at least six anticlines. Considering the effect of these upon subsequent denudation, particularly upon the direction of the flows of rivers, text-books dealing with the matter should be rewritten and a different exposition to the existing one should be given by teachers of geography and geology.

Excursions were conducted to Eridge Park and Costume Museum, and to Lewes, where the historic buildings were described by Mrs. E. Bradley, while material of interest to the botanists and zoologists on the Levels was shown by Dr. Langmead.

The sixty-second annual congress of the Union will be held next year in Hastings during April.

NATIONAL RESEARCH DEVELOPMENT CORPORATION

ANNUAL REPORT FOR 1954–55

THE report and statement of accounts of the National Research Development Corporation for the year ended June 30, 1955[*], records only 135 cases of assignment of United Kingdom patent rights to the Corporation by government departments and research councils, compared with 315 during 1953–54. Of the 597 inventions communicated to the Corporation during 1954–55 (compared with 664 during 1953–54), 203 were from government departments and research councils, 22 from official organizations of the British Commonwealth, 8 from industrial research associations, 54 from universities and 310 from private firms and individuals, 283 of which were British. Patent rights assigned to the Corporation during the year totalled 187, including 42 from universities and 9 from industrial research associations; holdings of British and foreign patents and patent applications at June 30, 1955, included 492 United Kingdom applications and 522 granted patents, and 982 overseas patent applications and 639 granted patents. The accounts show a rising trend in the return from the Corporation's activities when compared with its outgoings, the annual income of £94,749 during 1954–55 representing 61·3 per cent of the expenditure.

Of the projects initiated in previous years, the report notes that four of the six big electronic digital computers had been delivered, installed and accepted by June 30, 1955. The '401' computer, leased to the Agricultural Research Council, continues to operate satisfactorily at Rothamsted Experimental Station and has also been used in developing a numerical technique for predicting the predisposition of an aircraft to aerodynamic 'flutter', in which it has been demonstrated that the flutter speeds and frequencies may be conveniently and quickly computed by digital equipment. In addition, it has been used for computing the optimum trajectories of particles under acceleration in a cyclotron, with contributions to the understanding of cyclotron design. The response to grants for training computer engineers at the Universities of Manchester and Cambridge has been small. Uncertainties of marketing conditions and the absence of firm orders appear to be the chief barriers to obtaining licences for the Ricardo light steam engine, and prototype installations were being placed at the disposal of some Commonwealth governments for field trials and demonstrations. The production of hecogenin from sisal has been transferred to firms engaged in the industry on satisfactory commercial terms, and cortisone is being produced from the hecogenin now available. In view of the favourable report of a firm of chemical engineering consultants, the Corporation is continuing to support the acetylene synthesis project at the Imperial College of Science and Technology, London. Development of an experimental prototype stereoscopic motion-picture camera was completed during the year, and the camera is extremely promising.

Of the new projects, the Corporation is supporting an extended design study at the Manchester College of Technology of the possibility of controlling machine tools directly with a digital computer, and is sponsoring the development and initial marketing of Prof. H. S. Lipson's optical diffractometer. It is also financing the research and development work on the application of Prof. G. Pontecorvo's technique for synthesizing new strains of non-sexually reproducing micro-organisms, and is participating in a joint project with the Department of Scientific and Industrial Research and the Herring Industry Board to develop full-scale prototype equipment for commercial trials of new techniques of fish-smoking. Established projects now proving a useful source of revenue include those on the Bailey bridge, the Denny-Brown ship stabilizer, a technique for light-alloy cutting by electric arc, an air-position indicator, a course-setting dial-adjustment for aircraft, a backward-travelling-wave tube, a signalling system for teleprinter operation over radio links, a synthetic resin stoving enamel, a fire-fighting foam from degraded animal protein materials, a composition tablet for rendering brackish or sea water drinkable and an improved synthesis of an intermediate required in the production of the anti-malarial, 'Derraprim'.

UNIVERSITIES COUNCIL FOR ADULT EDUCATION

REPORT FOR 1954–55

THE report of the Universities Council for Adult Education for the session 1954–55[*] is critical of the Ashby report of adult education in Britain on two points: it has serious doubts regarding the administrative arrangements proposed for the annual assessment of grants to responsible bodies; and it regards the recommendation that a committee should be set up to advise the Minister of Education on the subjects and types of adult education courses which should receive priority in qualifying for grants as a serious threat to the academic freedom of the universities. The Council re-asserts its conviction that responsible bodies must truly exercise the responsibility of determining the form and content of their programmes, in shaping which consultation with the Ministry is always welcomed. When the Minister of Education intimated his acceptance of the recommendations of the Ashby Committee, this particular recommendation was specifically excepted, and friendly discussions with the Ministry have led to a mutually acceptable arrangement for assessing grants. The new Further Education Grant Regulations, issued in July 1955, contained the statement, according with the cardinal recommendation of the Ashby Committee for more active but flexible control of expenditure by the Ministry, that "in determining the amount of grant the Minister will have regard to the general standards of the courses, the needs of the area, the activities of other bodies providing further education in the area and the fees paid by students". The report remarks that it is to the sense of partnership built up, over the years, between the Ministry and the responsible bodies that we must look for a solution of the difficult problem of maintaining a reasonable control over expenditure while preserving the due rights and responsibilities of the responsible bodies.

---

[*] National Research Development Corporation. Report and Statement of Accounts for the Year 1st July, 1954, to 30th June, 1955. Pp. ii+20. (London: H.M.S.O., 1956.) 1s. net.

[*] Universities Council for Adult Education. Report on the Year 1954–55. Pp. 24. (From the honorary secretary and treasurer, W. E. Salt, University of Bristol, 1956.)

During the session under review the Minister was able to relax somewhat the severe limitations on grant-aid during the previous two sessions and, in particular, to give some assistance towards the mounting cost of tutors' salaries. Most extra-mural departments of universities at the end of the session reported a slight increase in the number of courses provided, the total of 4,302 exceeding the peak of 4,116 in 1950–51, while the number of students increased from 78,672 in 1953–54 to 84,752. The increase was largest in short courses of three to nine meetings (19 per cent) and smallest (0·9 per cent) in tutorial classes; sessional classes increased by 6 per cent. There was an increasing tendency, particularly in tutorial classes, to provide tutorial and sessional classes outside the traditional framework of collaboration with the Workers' Educational Association, and all this expansion has been achieved mainly with the help of part-time tutors, who increased in number from 2,342 to 2,768, 1,127 being university teachers; university lecturers appear to have been responsible for 57 per cent of the tutorial classes and 48 per cent of the sessional classes.

The extension lecture course is still an important element in most extra-mural programmes; but the majority of universities now use short extension courses in the broad field of the liberal studies as a means of interesting the general public in some aspect of university study and keeping those already interested abreast of recent developments. Such courses are often given by a team of lecturers. A variety of courses has also sprung up to provide for serious study by other kinds of student groups, particularly those with a good background of previous education. Many courses of the extension tutorial or study course type are provided in collaboration with societies or professional organizations, and an increasing proportion of extension courses is now run in this way. While some of these courses have a strong vocational appeal, all are liberal in subject-matter and treatment. In the post-war years, however, the universities are also providing courses directed to providing specific vocational groups with information on recent advances in university studies, especially in science and technology, mostly at a postgraduate standard. A striking feature of post-war development is the increasing use being made by extra-mural departments of residential courses, while there is now a remarkable amount of coming and going between Great Britain and foreign countries in the field of adult education. As regards subjects of study, the largest increases in the number of courses have been in the physical sciences (26 per cent), religion (17 per cent), history (12 per cent) and international affairs (12 per cent); the decline in psychology (5 per cent) and geography (10 per cent) has continued, and there has been a sharp contraction (31 per cent) in government. The demand for history is mainly for local history or archæology, and the study of languages appears to be on the increase. Interest in the social studies is much less marked, and the substantial increase in science courses is largely vocational.

Besides the Ashby report and the new regulations, the Council discusses the report on broadcasting and adult education prepared by Mr. Maurice Bruce and is concerned about the provision of books to adult classes. Its own inquiry in England and Wales has indicated that all thirteen universities and three of the eight university colleges have their own extra-mural libraries, usually administered separately, whether or not they are part of the university or college library. Issues to book boxes ranged between 2,000 and 10,000 volumes a year, and expenditure between £200 and £800 a year, with substantially higher figures for London and Oxford. Five of the sixteen extra-mural libraries supplied 90 per cent or more of the books required by classes; three between 70 and 90 per cent; and three between 50 and 70 per cent. In four instances 20–50 per cent of the supply came from the National Central Library and few libraries did not make some use of the National Central Library.

THE NATIONAL VEGETABLE RESEARCH STATION

OPEN DAY

THE first open day of the National Vegetable Research Station was held on June 5 at Wellesbourne, Warwickshire, when visitors saw the progress made in the development and work of this Station. Field experiments were on view, and there were exhibits of various aspects of the research in progress.

The Plant Breeding Section illustrated how it is using inbreeding, followed by the crossing of inbred lines, in an attempt to produce hybrid varieties of Brussels sprouts having improvements in uniformity, yield and other characters over ordinary varieties. Male sterility is being used as a helpful tool in this work, as it is also with onions, in the production of hybrid seed. The cause of deterioration of varieties of brassicas is also being investigated. F_3 progenies from crosses between lettuce varieties and a wild species, *Lactuca altaica* Fisch and Mey, which showed little attack by mosaic virus, were exhibited. These progenies were raised from the small proportion of F_2 plants which remained mosaic-free when grown in an epidemic of the disease. Stages in the process of breeding a non-bolting, high-quality variety of red beet having single-seeded fruits were shown, also work in the production of asparagus which should give only male plants from seed instead of the usual 1 : 1 ratio of male and female. Breeding material of forcing radish, spring cabbage and early cauliflower was also exhibited.

Long-term field experiments were seen which provide the Chemistry Section with material for its soil studies and work on the nutrition of vegetables. Descriptions were given of the effects of deep and shallow ploughing and of rotavating; of the application of fertilizers and farmyard manure at different depths, rates and times; and of inorganic and organic nitrogenous fertilizers on various rotations of vegetables. A demonstration was given of the restriction in development of the root system of peas brought about by soil compaction following certain cultivation treatments. Results from the use of chromatography in the study of the biochemistry of vegetables were shown, and this technique is being used in an investigation of a virus inhibitor present in rhubarb sap. A soil map of the Station's 280 acres was on view together with soil monoliths.

The Irrigation Section demonstrated the water-loss by transpiration and evaporation from cauliflowers during bright sunshine and showed that it was equivalent to about 200 gallons an hour per acre of growing crop. Different soil moisture meters were displayed together with data on their performance, and a prototype gauge was shown which indicated the minimum amount of water required to bring soil under a crop to field capacity; this gauge takes into account rainfall and water loss by transpiration and evaporation. The accuracy and efficiency of various techniques for measurement of leaf area were demonstrated, and the effects of different soil moisture conditions on growth, yield and quality of vegetables were shown.

The Entomology Section showed the life-cycle of the cabbage root fly, the damage it causes to brassica crops, and the most effective methods of controlling it. Illustrations were given of some natural predators of the pest and of insecticidal treatments which may destroy the predators, thus leaving a clear field for severe attack by the pest. The biology of the carrot fly, a serious pest of carrots, parsnips and parsley, was shown together with methods of insecticidal control involving seed dressings followed sometimes by supplementary sprays. A tasting panel assesses the degree of taint or off-flavour of carrots which may be brought about by certain insecticidal treatments. The life-history of the pea moth and the pea aphid and their control by DDT were demonstrated. Work in progress on the biology and control of lettuce root aphid was shown; but the recent discovery of varieties resistant to attack appears to offer the best solution of the problem.

The Pathology Section illustrated the life-history of the fungus which causes crook root disease of watercress, and the promising results obtained for the control of the disease by adding to the cress beds material which liberates minute quantities of zinc. It also showed the life-history of the bacterial pathogen found to cause the silvering disease of red beet seed crops, and the degree of control obtained by seed treatment with streptomycin. Methods of eliminating sources of infection by the fungus *Didymella* on outdoor tomato crops, and the effects of fungicides in checking the spread of the disease were exhibited. Parsnip canker has been found not to be invariably associated with damage by carrot fly larvae, and a fungus which can cause the disease has been isolated. Work in progress on virus diseases of rhubarb and watercress was exhibited, also some varieties of mint found to have resistance to mint rust. Results of studies on the control of *Botrytis* in lettuce by cultural methods and by fungicides were also shown.

The Weeds Section demonstrated techniques used in its ecological studies which are providing fundamental information necessary for the development of weed control in vegetable crops by cultural and chemical means. Changes in weed populations brought about by different manurial, cultivation and rotation treatments were described, and the effects of competition between weeds and vegetable crops at different stages of growth were shown. A demonstration was given of the effects of dinoseb (ammonium), dinoseb (amine), and a substituted phenoxybutyric acid MCPB as herbicides for market garden peas, also the degree of tolerance of different varieties to the sprays. The residual pre-emergence herbicide CMU was shown also to be useful for the control of annual weeds in asparagus beds.

The Statistics Section carries out investigations with the object of improving the efficiency of field experiments with vegetables, in addition to its advisory work for other Sections and for outside bodies on the design and analysis of experiments. In studies on the origin of experimental errors in the field, the effects of different methods of sowing peas, and of using different size grades of cauliflower plants when planting in the field were demonstrated. The economics of spacing of glasshouse and frame lettuce were illustrated, and work in progress was shown on the genetics of continuous variation in French beans.

J. PHILP

NOCTURNAL TEMPERATURE PROFILE ABOVE BARE SOIL ON CLEAR NIGHTS

It has long been established that in the lowest few hundred feet of the atmosphere there is on calm clear nights on the whole an inversion (that is, temperature increases with height), presumably determined by radiation of heat from the ground. The observations of Johnson and Heywood at Leafield (Meteorological Office Geophysical Memoir 77; 1938) showed that this inversion comes into being remarkably suddenly about sunset. As part of this structure it was supposed that the lowest temperature was normally to be found on the ground surface itself, the air above being cooled by loss of heat to the ground by conduction and convection. Doubts as to whether this was always so have been expressed for a long time. J. Glaisher in 1847 reported that on all clear nights in the year 1843–44 the mean minimum temperature on short grass was 0·8 deg. F. higher than that recorded 1 in. above the top of the grass. Many other workers have found the temperature on radiation nights to be sometimes lower a few inches above the surface than on the surface; but such a structure has not been regarded by meteorologists as a regular feature.

J. V. Lake, of the University of Reading, has recently described in the *Quarterly Journal of the Royal Meteorological Society* (April 1956) the results of temperature observations with the most up-to-date instruments in the lowest few feet over bare soil on calm clear nights. Lake measured temperatures with both minute thermistor beads and with ordinary unscreened alcohol-in-glass minimum thermometers at heights of 0·1, 0·5, 1·5, 2·5, 3·5 and 54 in. The results were all the same: minimum temperature at 2–3 in. above the surface, with an inversion above and a super adiabatic lapse-rate below. For completeness the surface radiation temperature was measured with a spirit thermometer. On the early morning of March 22, 1955, the surface radiation temperature was 21° F. and the temperatures at the higher levels specified above were, in the mean of fifty-two observations at each height, respectively: 18·6, 17·3, 16·6, 16·4, 16·8 and 18·4° F. The standard deviations of the observations were 0·93 deg. F. at 0·1 in. and 0·35–0·46 deg. F. at higher levels.

The temperature profile below the minimum is of the kind which occurs over a surface strongly heated by sunshine having a lapse-rate more than a thousand times the value of the dry adiabatic lapse-rate (1 deg. F./2,187 in.) and even hundreds of times the so-called 'auto-convective' lapse-rate (1 deg. F./640 in.) at which the density of the air increases upwards. As a by-product of the investigation, it was found that the reduction of surface temperature below the value at sunset was proportional to the square root of the time, in agreement with Brunt's theory of surface-temperature changes on radiation nights, which takes no account of interchange of heat between air and ground and balances radiation loss from the ground against conduction of heat upwards in the soil. The observations were made under dead calm conditions over a level field at a point 100 yards from the nearest boundary, so that vitiation by horizontal influx of colder air seems to be ruled out, and Mr. Lake shows that instrumental errors cannot account for the profiles.

The detailed physical reason for the profile is still obscure. It appears that the air near the ground under calm conditions loses heat by radiation rather than by convection and conduction until a state of radiative equilibrium is reached depending on the water vapour content. The fact that the variation of the surface minimum temperature agreed well with Brunt's theory supports this. It is very desirable, because of the great importance of accurate forecasting of minimum temperatures for agricultural purposes and for general scientific reasons, that an adequate physical theory of the temperature distribution in the lowest foot of the air on radiation nights should be found.

THE CAPERCAILZIE

An account of the feeding habits and breeding behaviour of the capercailzie has been set out in No. 37 of the Forestry Commission's admirable leaflets. The capercailzie well merited the delightful names by which it was known in medieval times—cock of the woods, horse of the woods, avercalzie, auercalze, wild peacock, wild turkey—for the cock caper is one of the finest game-birds in Europe. In the British Isles, it is found only in the woods and forests of Scotland.

The cock bird is about a yard in length, with the hen capercailzie a foot shorter. Originally, the capercailzie was found in England, Wales and Ireland, as well as Scotland; in England the birds became extinct around 1660–70. In Scotland, the last two positive references to truly native birds seem to be those from the Abernethy and Glenmoriston districts in 1771. The capercailzies present in Scottish woods and forests to-day owe their presence to an introduction of Swedish birds, made in 1837. Then, Lord Breadalbane imported thirteen cocks and nineteen hens and turned them out on his estate at Taymouth Castle, near Aberfeldy, in Perthshire. Unlike previous introductions elsewhere, this one was so successful that after twenty-five years there were more than a thousand birds present on this estate alone.

The typical habitat of the capercailzie consists of hillsides with woods of mature Scots pine. Capercailzie appear to be invading Forestry Commission plantations of Scots pine, larch and spruce when these reach a height of about twenty-five feet.

In winter, the capercailzie's food includes the shoots, buds, leaves, seeds and young cones of the Scots pine, and occasionally those of other conifers. These, however, form only a small proportion of its total food supply, and where only relatively small numbers of capercailzies are found amid middle-aged or maturing pinewoods, little serious economic damage results. The position may be very different in young, newly established plantations, particularly where these lie close to older woods with a heavy stocking of capercailzies. These birds find the winter buds and growing shoots of the young pines very palatable, and all too often they peck out the leading bud, thus causing serious loss of annual growth, and perhaps a distorted stem. Further damage may be done because of the bird's weight; if it settles on a side branch this may break away from the main stem, causing a serious wound to the tree.

Whether or not control measures are necessary depends on local circumstances. In the older woods, the harm the capercailzie does is negligible. Under other conditions, for example, where the felling of mature woods has driven the birds to take refuge in young plantations, it may be necessary to restrict the numbers of the birds in order to avoid serious loss of timber production. Control is commonly effected by shooting, which, owing to the bird's large size and conspicuous appearance, presents no particular difficulties. Provided it does not become unduly numerous in the younger plantations, this interesting and beautiful bird may be tolerated and even encouraged.

FAT FORMATION IN A DIATOM

The photosynthesis and formation of fats in a diatom, *Navicula pelliculosa*, using carbon-14 as a tracer, has been investigated in some detail by G. E. Fogg (*Ann. Bot.*, N.S. 20, 78, 265; 1956). Fixation into the following cell fractions was determined: (*A*) material soluble in 80 per cent ethanol but insoluble in benzene; (*B*) material soluble both in 80 per cent ethanol and in benzene; (*C*) material insoluble in 80 per cent ethanol. Carbon fixed in photosynthesis was incorporated, rapidly and in amounts representing up to 70 per cent of the total fixation, into fractions *B* and *C*, as well as into fraction *A*. Considerable variation was found in the proportions of carbon entering the three fractions in the light; in actively growing cells the proportion entering fraction *C* preponderated over that in *B*, corresponding to the synthesis of protein, whereas in nitrogen-deficient cells fixation in *B* was the greater, corresponding to the synthesis of fat.

These patterns changed only slowly, over periods of days, following the transfer of cells to altered conditions of nitrate supply. However, when ammonium nitrogen was supplied to nitrogen-deficient cells a marked change in distribution of carbon fixed occurred within 5 min., fixation in fraction *B* falling to a low value and that in *A* rising correspondingly. In cells subjected to prolonged nitrogen-deficiency, fixation in fraction *B* fell to a relatively low value; but the proportion which this fraction formed of the total dry matter in the cells rose as a result of an increased rate of loss from the cells of constituents other than lipides. The distribution of carbon fixed was also dependent on light intensity. Fixation in fractions *B* and *C* rose relatively to that in *A* as light intensity was increased up to 100 foot-candles but fell again at the highest intensity used, 2,000 foot-candles.

ELECTRICAL STIMULATION OF THE HYPOTHALAMUS AND THYROID ACTIVITY

By PROF. G. W. HARRIS, F.R.S., and JAMES W. WOODS

Institute of Psychiatry, Maudsley Hospital, London, S.E.5

MUCH interest has been focused on a possible relationship between the central nervous system and the activity of the thyroid gland by the numerous accounts relating psychological trauma with the onset of hyperthyroidism in the human. In recent reports[1,2] the type of individual and the kind of emotional disturbance involved have been described. However, attempts to demonstrate changes in thyroid activity following electrical stimulation of the hypothalamus have not been entirely satisfactory. No increase in oxygen consumption was observed following prolonged stimulation of the hypothalamus; but definite conclusions were not drawn from these data owing to the limitations of the method for measuring metabolic rate in rabbits[3]. Histological signs of increased thyroid activity in rats and rabbits, in which the hypothalamus had been stimulated for four 1-hr. periods on each of two days, have been reported[4].

In the present work the effect of electrical stimulation of the hypothalamus on the thyroid activity of unanæsthetized and unrestrained rabbits has been studied. Electrical stimulation was performed by a modification of the remote-control method previously described[5]. Coils, of about 3,000 turns, were implanted subcutaneously over the lumbar spine and connected by subcutaneous leads to electrodes fixed to the skull vault with dental cement. Stimulation was carried out for periods of 1–7 days, usually 2 days. Changes in thyroid activity were detected by the use of the 'thyroidal ^{131}I release curve'[6]. Following the administration of a single tracer dose of thyroidal ^{131}I this method allows either an increase or decrease in thyroid activity to be observed rapidly and continuously over periods of about 10–14 days. In seven cases the plasma protein-bound or total iodine-131 was measured at intervals throughout an experiment.

Thirty-seven experiments have been performed on twenty-three rabbits in which electrical stimulation (either bipolar or unipolar) has been applied to the pituitary gland (five animals) or some region of the hypothalamus (eighteen animals). These experiments were performed on normal rabbits (twenty-five experiments), after right adrenalectomy (three experiments) and after ovariectomy and right adrenalectomy (nine experiments). In thirty-four experiments either a decrease (twenty cases) or no change (fourteen cases) in thyroid activity was observed. In two experiments (on one normal rabbit) a definite increase in thyroid activity occurred, and in one experiment on another rabbit (after right adrenalectomy) a questionable increase in thyroid activity was seen.

In contrast to the above results are those obtained after removal of the remaining adrenal glands. Up to the present, fourteen of the rabbits described above have been studied after complete adrenalectomy, while being maintained on constant daily doses of cortisone. Electrical stimulation evoked a marked increase in thyroid activity in twenty experiments on ten animals. (Previous to adrenalectomy these ten animals had shown thyroid inhibition in ten experiments and no change in thyroid activity in five experiments.) Ten experiments on the other four animals showed no observable change in such activity on eight occasions, a questionable increase on one occasion and an inhibition on one occasion. The precise localization of the region stimulated in the various animals has not yet been determined, since many of the rabbits are still alive. However, radiographic studies of the animals' heads suggest that it is stimulation of the median eminence of the tuber cinereum which results in increased thyroid activity. During five experiments on four rabbits in which increased thyroid activity was observed from measurements of thyroidal radioiodine, estimations of the plasma radioactivity revealed a marked increase (up to × 3½) during the period of stimulation. It is of interest that hypothalamic stimulation could maintain an increased level of thyroid activity even in the presence of a high concentration of thyroid hormone in the blood. Five out of the ten rabbits that showed a clear-cut acceleration of thyroid activity during stimulation eventually died suddenly, and unexpectedly, while being stimulated.

The change of the thyroid response to electrical stimulation of the tuber cinereum after adrenalectomy may be explained in several ways. First, it has been shown that administration of adrenaline may result in inhibition of the thyroid gland in the rabbit[7–9], and it may be argued that stimulation of the hypothalamus, in the intact or unilaterally adrenalectomized animal resulted in increased secretion of adrenaline, which in turn prevented any increase in thyroid activity. This explanation seems unlikely, since stimulation of the midline tuber cinereum does not evoke secretion of adrenaline[10], and since the dose of adrenaline necessary to produce prolonged inhibition of the thyroid gland of the rabbit is high[8]. Secondly, administration of adrenocorticotrophic hormone or cortisone has been found to inhibit thyroid activity in the rabbit[11,12]. It is possible that the stimulation of the tuber cinereum caused increased secretion of adrenocorticotrophic hormone by the pituitary gland and that the raised blood-level of adrenal steroids prevented any increase in thyroid activity. Stimulation of the tuber cinereum has been shown to result in pituitary discharge of adrenocorticotrophic hormone[5,13–15], and the dose of cortisone required to reduce thyroid activity in the rabbit is within the physiological range, therefore this explanation seems to be the most likely. The site of action of cortisone in inhibiting thyroid function appears to be the pituitary gland or hypothalamus, since it has been found[12] that cortisone did not modify the thyroid response of the hypophysectomized rabbit to administered thyrotrophic hormone. It would seem then that electrical stimulation of the tuber cinereum in the normal rabbit excites the liberation of adrenocorticotrophic hormone and thereby increases the concentration of adrenal steroids in the blood, which tends to inhibit the pituitary release of thyrotrophic hormone. In the adrenalectomized animal on constant cortisone maintenance therapy similar stimulation does not result in a sudden rise in blood concentration of adrenal steroids, and consequently an increased discharge of thyrotrophic hormone follows.

These results are of interest in relation to Graves's disease for two reasons: (*a*) as regards the possible role of emotional upsets and the central nervous system in the etiology of the condition[1,2]; (*b*) as regards the high frequency of the condition in patients suffering from Addison's disease[16], and the signs of adrenocortical underactivity (lymphoid hyperplasia, large thymus, lymphocytosis and reduced urinary excretion of 17-keto-steroids)[17–19] and the small adrenal cortex that are present in such cases[20].

This work was supported by a grant from the Research Fund of the Maudsley Hospital and was carried out during the tenure of a fellowship (by J. W. W.) from the American Cancer Society.

STUDY OF ANTICHOLINESTERASE ACTION IN INSECTS BY A LABELLED POOL TECHNIQUE

By F. P. W. WINTERINGHAM and A. HARRISON

Pest Infestation Laboratory, London Road, Slough, Bucks

WHEN insects are fed or injected with a suitable compound labelled with a radioactive isotope, a whole range of biochemically related metabolites becomes labelled. The insects can then be killed and extracted in entirety or as some dissected portion under conditions likely to preclude further enzymic or chemical changes. The extracted mixture can be resolved by paper chromatography and the separated labelled metabolites located and determined by scanning the paper chromatogram radiometrically.

This provides what may be described as the spectrum of labelled metabolites which obtained in the living tissues at the instant of death. By comparing the spectra so obtained from control and from poisoned insects, it has been possible to study quantitatively the biochemistry of insecticidal action *in vivo*. Only those compounds undergoing sufficiently rapid turnover will become effectively labelled, but these are the compounds most likely to be important in the minute-to-minute survival of the animal and likely, therefore, to be involved in any acute biochemical lesion. The preparation of the large numbers of radiochromatograms (radioactivities plotted against distance along the paper chromatograms) required by these studies is greatly assisted by automatic radiometric scanning and elution techniques of the kinds described elsewhere[1,2]. These techniques were first used to investigate the effects of insecticides on the phosphorus metabolism of insects[3,4]. By injecting 2-^{14}C-acetate into adult houseflies, they have been successfully extended to non-phosphorus-containing metabolites. Some of the results obtained, particularly in relation to anticholinesterase action in insects, were interesting and, to us, surprising. They may be of comparative significance in vertebrate biochemistry and a preliminary report was thought to be worth while.

2-^{14}C-Acetate was chosen as the initial substrate because of its ubiquitous and central metabolic rôle. The isotopic methyl carbon seemed less likely to be lost as carbon dioxide as the result of the operation of Krebs's cycle, etc., than the carboxyl carbon. Week-old adult houseflies (*Musca domestica* L.) were injected intrathoracically while under mild *cyclo*-propane anæsthesia with 1 µl. of water containing 18 µgm. of 2-^{14}C-sodium acetate equivalent to 2 µc. of carbon-14. Immediately afterwards, 1 µl. of acetone (control) or 1 µl. of acetone containing 10 µgm. of di*iso*propylphosphofluoridate was applied topically to the dorsal surface of the thorax of each fly. The flies were then confined to glass metabolism chambers at 30° C. There was provision for recording automatically and continuously the rate of oxygen consumption by the flies and for the collection, and later chemical and radioassay, of the expired carbon dioxide. After 0·5, 2·0, 5·0 hr., and, in the case of controls only, after 24 hr., groups of twenty flies were removed from the chambers while under mild *cyclo*propane anæsthesia, plunged into liquid nitrogen, rinsed in non-radioactive alcoholic acetate at $-10°$ C., and dissected on a cold slab of solid carbon dioxide.

Heads or thoraces (minus leg and wing appendages) were homogenized in 0·2 *N* sulphuric acid in aqueous ethanol at $-10°$ C., centrifuged at 5° C. and the

clear supernatant poured off. The residue was re-extracted as before and the supernatants pooled. The acid was exactly neutralized with saturated aqueous barium hydroxide and the barium sulphate centrifuged down at a *p*H adjusted to 1·3 with hydrochloric acid. In this way 2-ml. extracts equivalent to twenty heads or thoraces were prepared and stored at −15° C. Aliquots of 20–100 μl. were fractionated paper chromatographically in an aqueous–formic acid–acetone solvent as described for labelled phosphorylated intermediates[3].

Seven distinct ^{14}C-labelled fractions (I to VII), running with mean R_F values of 0, 0·25, 0·47, 0·58, 0·66, 0·75 and 0·91 respectively, were resolved. By co-chromatographic techniques[3], fractions III, V and VI, representing some 75 per cent of the total soluble carbon-14, were identified as free glutamine, free glutamic acid and free proline, together with smaller fractions of other amino-acids. Surprisingly, less than 3 per cent of the thoracic carbon-14 was found as free alanine, and less than 1·5 per cent as free aspartic acid, although these acids are known to occur freely and in high concentrations in insect tissues[5]. They were expected to have become labelled as the result of transaminase reactions with pyruvate and oxaloacetate as occurs in vertebrate systems[6]. Hydrolysis of the thoracic protein recovered in the insoluble fraction of the original homogenate showed that almost all the protein carbon-14 was present as glutamate and proline only, which suggests that these protein amino-acids were in equilibrium with the free amino-acids. When the fastest running fraction (VII) was reconcentrated[2] and paper chromatographed in aqueous *n*-propanol–formic acid as described for separating choline esters[7], it gave a single major fraction running with an R_F value of 0·8. However, on scanning the paper chromatogram within the sensitive volume of a specially constructed 4-π Geiger–Muller tube[8], a minor fraction, running with an R_F value of 0·47, was readily located and assayed. This labelled fraction and added unlabelled acetylcholine (located with iodine[7]) could never be resolved in acid solvents. The carbon-14 activity was lost in ammoniacal solvents[7]. No detectable fraction of the soluble carbon-14 behaved as free choline, which would almost certainly have been present in the extracts[9]. The proportion of carbon-14 found in the acetylcholine fraction was independent of the weight of unlabelled acetylcholine added at any stage of the fractionation, so that no isotope exchange had occurred between carrier and some other labelled metabolite.

These observations provide independent chemical evidence for the presence of acetylcholine in the thoracic and head tissues of the adult housefly[9,10], the ester here being labelled *in vivo* in the acyl moiety only. The overall carbon-14 spectrum of the control flies did not change drastically over the 24-hr. period studied. Isotopic equilibrium between the soluble metabolites was thus effectively established within 0·5 hr., and the relative carbon-14 contents of the separated fractions were measures of their *relative* chemical concentrations at a particular time. The mean carbon-14 activities recovered in the soluble fractions are shown as a percentage of the total soluble carbon-14 in Table 1. The effects induced by di*iso*propylphosphofluoridate mentioned below were very much larger than the differences in carbon-14 distribution observed in replicate analyses and were obviously significant.

It will be seen that di*iso*propylphosphofluoridate caused an increase in glutamine at the expense of the proline–glutamate fraction, especially after 5 hr. No effects are reported for the 24-hr. exposure because at this time most of the flies treated appeared to be dead and respiration had almost ceased; irrelevant post-mortem effects could not then be excluded. The glutamine accumulation suggests that di*iso*propylphosphofluoridate may have rendered necessary an ammonia detoxication mechanism[11]. In a parallel study by the phosphorus-32 labelled pool technique[3], it was shown that topical exposure to di*iso*propylphosphofluoridate for 5 hr. had no significant effect on the thoracic levels of adenosine phosphates or other phosphorylated intermediates, and there was no evidence for the formation of inosine phosphates. The ammonia, then, was not derived by deamination of adenine nucleotides. At 5 hr. all the flies appeared to be alive, and while the rate of oxygen uptake was about normal at this time, it was steadily falling after having reached double the control value at 2 hr. Apart from convulsions within minutes of the application of di*iso*propylphosphofluoridate the flies lay motionless until death except for some slight and laboured leg movements. The failure of this substance to exert any detectable effect on the phosphorus metabolism lends no support to a suggestion that some related phosphorus compounds may exert their insecticidal action in this way[12].

Of interest was the relative rise in acetylcholine in head and thoracic tissues after 0·5 hr., followed by a fall to normal or near normal values after 2 and 5 hr. Since death ensued much later still, it appeared that the expected but temporary accumulation of acetylcholine was not the fatal lesion *per se*, despite the fact that di*iso*propylphosphofluoridate is a potent and relatively irreversible anticholinesterase[13] and has been believed to exert its toxic effect in insects by the same mechanism[14]. The fall in acetylcholine suggested that the esterase inhibition was reversible *in vivo*, or that the choline acetylase system was impaired despite evidence to the contrary[13]. The possibility of alternative pathways of acetylcholine metabolism in insects cannot, of course, be discounted.

By using large aliquots (0·5–1·0 ml.) of the unfractionated thoracic extracts, it was possible to assay the apparent acetylcholine-levels by their action on the rectus abdominis muscle of the frog. The results so obtained by Mr. S. E. Lewis of this Laboratory are given at the foot of Table 1. They confirm the rise and fall found radiochemically. These results suggested a careful investigation of the choline acetylase and acetylcholine esterase-levels in intact insects at different stages of di*iso*propylphosphofluoridate poisoning, the results of which will be reported separately (Lewis, S. E., personal communication). There is some evidence that the level of acetylcholine may fall in vertebrate tissues following an initial rise as the result of anticholinesterase action; but in these cases the inhibition of the acetylcholine esterase was much less likely to be either complete or irreversible[15]. The acute effects of anticholinesterase action in mammals may be largely ascribed to the failure of the neuromusculature of respiration and the consequent anoxia[16]. Therefore, the toxic mechanism was presumably different in these insects, the respiration of which depends largely on diffusion processes[17] and was in any event maintained at a supra-normal level well beyond the time when acetylcholine accumulation was demonstrable. The accumulation of glutamine together with the absence of certain other sustained effects indicate some disturbance in amino-acid metabolism, and this disturbance may have been the fatal lesion in these insects.

This communication is made by permission of the Department of Scientific and Industrial Research.

RESOLVING POWER OF GENETIC ANALYSIS

By Prof. G. PONTECORVO, F.R.S., and Dr. J. A. ROPER

Department of Genetics, University of Glasgow

GENETIC analysis resolves the genome into linkage groups and the linkage groups into loci which can be graphically represented as arranged in a line. Each linkage group has its structural basis in a chromosome and each locus in a small segment of a chromosome. In the case, more unique than rare, of the giant chromosomes of the salivary glands of *Drosophila*, a locus can be identified microscopically with a precision of one band. One band, however, is still a structure of considerable size, more than 1 μ, along the axis of the chromosome.

Though the extraordinary resolving power of genetic analysis, unequalled in biology, was pointed out some years ago[1], the advances made since then render it advisable to restate the questions which it raises. We should do this for two main reasons. One is that this resolving power has increased very considerably, mainly because of the use of micro-organisms, and of selective techniques applied to micro-organisms, for genetic analysis. With some of these techniques the number of products of meiosis which it is feasible to analyse in any one experiment is of the order of 10^8. Recombination fractions of the order of 10^{-6} have already been measured in our laboratory in the mould *Aspergillus nidulans*[2].

The other reason is that we know at present a little more about the chemistry of the chromosomes. We may thus attempt to give a chemical meaning to what genetic analysis resolves, and perhaps even to what is the basis of the process on which genetic analysis is based, that is, crossing-over. In this direction a remarkable paper by Benzer[3] on bacteriophage has already given a lead. In the present paper, Benzer's attempt will be used in a comparative approach.

In the first place, let us see some extreme examples of resolution by means of crossing-over (Table 1). These are all examples of crossing-over between alleles of one gene or, as we prefer to put it, between mutational sites of one 'section' of the linkage map[4]. One section is defined as that part of a chromosome within which recessive mutants behave as allelic of one another, that is, determine a mutant phenotype when in combinations of two in *trans* but not when

Table 1. EXAMPLES OF VERY HIGH RESOLUTION BY MEANS OF CROSSING-OVER BETWEEN ALLELES IN SECTIONS WHERE MORE THAN TWO MUTATIONAL SITES HAVE BEEN IDENTIFIED

Organism and reference	Mutational sites so far identified No.	Sum of recombination fractions between the two sites found farthest apart (*a*)	Recombination fraction between the two sites found closest together (*b*)	Ratio *a*/*b*
Aspergillus				
bi	3	1×10^{-3}	4×10^{-4}	2·5
ad 8	4	$1·8 \times 10^{-3}$	$1·2 \times 10^{-5}$	150
Drosophila				
bx	5	3×10^{-4}	3×10^{-5}	10
lz	3	$1·5 \times 10^{-3}$	6×10^{-4}	2·5
w	3	5×10^{-4}	8×10^{-6}	62
Phage *T*4				
r II (*A*)	33	$4·3 \times 10^{-2}$	$1·3 \times 10^{-4}$	330
r II (*B*)	21	$3·5 \times 10^{-3}$	1×10^{-3}	35

Refs. 3, 7, 8, 9, 10 and Mackendrick (unpublished)

in *cis* ('Lewis effect'). The examples given are only for cases in which more than two mutational sites are already known, so that at least two intervals have been measured. There are, however, four more examples in *Aspergillus*, not included in the table because in each case only two mutants have been tested against one another, in all of which the recombination rates were of the order of 1×10^{-6}.

If we assume in first approximation that the recombination fraction between two non-adjacent mutational sites is the sum of the recombination fractions in all the intervening intervals, then the values in column (*a*) of Table 1 divided by the values in column (*b*) will give minimal estimates of the possible number of intervals in any section. These estimates, being minimal, have an interest only when they have high values. In the case of *ad* 8 in *Aspergillus*, of *w* in *Drosophila*, and of both *r* II (*A*) and *r* II (*B*) in phage, these values run into several tens or hundreds.

What does this tell us ? It tells us that, if the above assumption is not quite invalid, the number of mutational sites within one section of allelism (or gene) separable from one another by crossing-over may run into high numbers. That this is likely to be so can also be deduced from the independent evidence that alleles of one gene originated by different mutational events even if otherwise indistinguishable do usually cross-over with one another, that is, they represent mutation at different sites. Clearly, if the sites at which mutation can occur in one gene are numerous, the chance that two mutants of independent origin involve the same site or group of sites is small[4].

The next step is to consider what part of the total genetic map the smallest recombination fractions so far measured represent. The data are in Table 2. These smallest fractions represent 2×10^{-7}, $2·8 \times 10^{-6}$ and 6×10^{-5} of the total map in *Aspergillus*, *Drosophila* and phage, respectively. In other words, we have already resolved the total maps down to fractions of the order of less than one-millionth in some cases, and the available techniques are by no means exhausted. In fact, they could still resolve, without any improvement, linkages one or two orders of magnitude closer. The point is that we cannot at present deduce from first principles where the ultimate limit should be.

Table 2 SMALLEST RECOMBINATIONS MEASURED IN THREE ORGANISMS EXPRESSED AS A FRACTION OF THE TOTAL MAP

	Total map units (*a*)	Minimum recombination so far measured (*b*)	Ratio *b**/*a*
Aspergillus	>500	*paba* 1–*paba* 6 1×10^{-6}	2×10^{-7}
Drosophila	280	*w*^{aE}–*w* 8×10^{-6}	$2·8 \times 10^{-6}$
Phage *T*4	200	*r* II (55)–*r* II (247) $1·3 \times 10^{-4}$	6×10^{-5}

Ref. 3 and Roper (unpublished) and Mackendrick (unpublished).
* *b* here calculated as recombination percentage

The final step is to give chemical meaning to what we are resolving. In this we can follow Benzer's[3] argument, and try to see what happens when we apply it to organisms other than phage. The deoxyribonucleic acid content of a haploid nucleus (or particle) in *Aspergillus* is 0·044 gm. $\times 10^{-12}$ (from the data of Heagy and Roper[5], after correcting an obvious error). In *Drosophila*[6] this content is 0·085 gm. $\times 10^{-12}$ and in phage *T*4 0·0002 gm. $\times 10^{-12}$. These values correspond to 4×10^{7}, $7·7 \times 10^{7}$ and 2×10^{5} nucleotide pairs in *Aspergillus*, *Drosophila* and phage, respectively. Let us now assume that : (1) all deoxyribonucleic acid constitutes the linear backbone of chromosomes or of phage particles ; (2) that crossing-over involves nucleotide linkages ; and (3) that the probability of crossing-over is the same at all nucleotides, or repeat of nucleotides. From the data of Table 2 and the values for the nucleotide content just given we can calculate, as Benzer has already done for phage, to how many nucleotide pairs the smallest recombination fractions measured correspond. The number of nucleotide pairs multiplied by the values in the last column of Table 2 gives eight nucleotide pairs for *Aspergillus*, 216 for *Drosophila* and 12 for phage.

These very crude estimates would suggest a few nucleotide pairs as the size of the intervals so far resolved between mutational sites. If the backbone of the chromosome were thought of not as a simple Watson–Crick structure but as a multiple, the number of nucleotide pairs per interval would correspondingly be reduced lengthwise and increased sidewise.

Extending the present reasoning to a whole section of allelism (a gene), it turns out from Table 1 that it could include as a minimum 1,000–8,000 nucleotide pairs in *Aspergillus*, and the same order in *Drosophila* and phage ; and we could even speculate further that this is the sort of template required for making a protein.

All these are amusing exercises in numerology. They may even have some heuristic value if they are taken for nothing more than what they are ; in particular, if we keep in mind that crossing-over resolves sections held together by bonds, but tells us nothing about what these bonds are and what they hold together. However, there is one solid fact, and this is precisely why we have written this paper. With crossing-over we can analyse the genetic map down to less than one-millionth of it. Even if the total material of the nucleus went into the bonds which we are resolving, we would still have a biological tool of amazing sensitivity, a sensitivity which biochemistry still lacks.

Imprinting and the Evolution of Instincts

DR. R. E. EWER's communication[1] on this subject calls for some comment. She is concerned with only one of two evolutionary processes. A mode of behaviour may be a learned activity in ancestors, and an unlearned or instinctive one in descendants, *or conversely*. For example, Reyniers[2] reported that newborn rats do not urinate without an external tactile stimulus, but soon 'learn' to do so when their bladders fill. One cannot suppose that no ancestors of the rat urinated without external stimulation. In those bird species so far studied the pattern of song is reported to be learned and unlearned in about equal numbers. Lorenz[3] and Kramer showed that in *Lanius collurio* the practice of spearing insects on thorns was unlearned when nutrition was optimal, but had to be learned when it was deficient. Spalding[4] found that some domestic fowl chicks avoided wasps without learning, others only after being stung. It seems unlikely that the passage from learning to instinct is irreversible.

Dr. Ewer's suggestion as to the evolutionary process by which learned activities are replaced by unlearned is very similar to our own[5,6]. But we doubt[6] whether it is applicable to imprinting, which James[7] described as "the inhibition of instincts by habits". A young nidifugous bird instinctively follows a variety of moving objects. It may get the habit of following only one class of these, for example, ducks or human beings, and it may afterwards perform other activities only on seeing members of this now inappropriate class. Also the development of the usual appropriate adult reactions to members of this class may be inhibited. These reactions and inhibitions are exploited by husbandry. The good shepherd and the good goose-girl lead their flocks, rather than drive them. We think that the word 'imprinting' should be confined to the consequences in *adult* life of infantile experiences. These have not so far been investigated in the recent experiments on following reactions[8-11].

The end results of an imprinting process are remarkably unlike the typical examples of instinctive behaviour, as Lorenz[12] has repeatedly emphasized. An instinctive activity has a somewhat stereotyped motor pattern, and is evoked by a 'releaser' providing 'sign stimuli' which are usually visual or auditory patterns so simple that they can readily be replaced by dummies, that is, these patterns have a simplicity comparable to the patterns of traffic signals designed to make conditioned discrimination easy, and to the patterns which are shown by aposematic animals[13]. Imprinting, in birds at least, seems to be to a *Gestalt*, and many complex activities are directed, and complicated motor adjustments made, to the unusual partner. For example, birds imprinted to human beings often react to both human sexes, and their reactions reveal the many interpretations they put on the variation in human dress[14].

We agree with Dr. Ewer that an instinct is a danger in evolution. An 'innate releasing mechanism' or a 'fixed pattern' of motor activity makes adaptation to new environments *and* to evolutionary changes within the species concerned difficult. Wild poultry kill chicks which do not have the normal colour pattern, and thus make adaptive changes in it impossible except at a very slow rate. Many species have probably become rare or extinct because they could not adapt their behaviour to the changes produced by men. On the other hand, capacities for imprinting do not seem to have been impaired by domestication, which indeed seems to have been built on such capacities[15], even though it might *a priori* have been expected that herding with men and members of other species would have produced selection pressures against a capacity which could lead to incorrect sexual fixation.

Secondly, the capacities which we call learning have been evolved to show a much wider range of variation than morphological characters. Our memories differ among themselves much more than our bodies, and this variation contributes to, rather than detracts from, Darwinian fitness. To paraphrase James in contemporary jargon: an instinct is a behaviour pattern in which developmental homeostasis results in inconspicuous variation both in postnatal development and adult phenotype, whereas a learnt process or lesson involves demonstrable postnatal developmental flexibility[16] and usually results in adaptive variation among the adult phenotypes.

We think that any attempt to apply Waddington's[17,18] technique for what he calls genetic assimilation, so that a learnt response in ancestors is replaced by an unlearnt one in descendants, is only likely to succeed in special circumstances. If the exercise to be learnt is so 'difficult' that it can only be mastered by a small fraction of the ancestral stock, then, by breeding from this minority, in each generation, for many generations, one would hope that the fraction which can learn the task would gradually increase. The question is: Are the developmental processes which we call learning sufficiently like those concerned with wing vein and thoracic development in *Drosophila* for such a selection to result in a fraction of the population performing the task without the environmental stimulus which in the sort of experiment which we are considering would be called the exercise or the experience? Waddington has so far only obtained the genetic assimilation of phenotypes which are the result of gross disruption of the normal canalizations (morphoses). It is probable that the assimilation of 'adaptive hypertrophies' to which learning can be compared[19] would require special selection pressures; for example, adaptedness would have to be made to confer more fitness than adaptability during postnatal life. In Waddington's metaphor, the walls of an entire epigenetic canal would have to be built up higher and steeper.

We are doubtful whether selection for speed of learning which Dr. Ewer suggests would be effective, as this would merely select for animals of what Pavlov called the excitatory or choleric type[20], which can readily learn excitatory reflexes, but not inhibitory ones.

The only example which we know in the literature where selection for a learning ability may be said to have produced a change in the instinctive behaviour of the selected stocks is that recorded by Krechevsky. Tryon had selected 'bright' and 'dull' rats for seven generations. The former learned to find their way through a maze in darkness more rapidly than the latter. Krechevsky[21] found that when confronted with an insoluble problem, in which the correct path was constantly varied, the 'bright' rats chose 'spatial hypotheses', for example, tried right-hand openings before left-hand. The 'dull' rats tried 'visual hypotheses', for example, dark rather than light openings. What Krechevsky called a hypothesis might be called a type of instinctive behaviour. Krechevsky[22] found that lesions of the striata (visual) area of the cortex reduced the tendency to use visual hypotheses, while lesions of the precentral (motor and somaesthetic) area reduced the tendency to use spatial hypotheses.

Recruitment and Maturity of the East Anglian Herring

Identification of groups of herring in the southern North Sea by the size of the central zones on their scales, expressed as a proportion of the total length of the fish, l_1, was first applied by Hodgson[1]. We have now used it to confirm that in 1952 the recruits to the East Anglian fishery comprised virtually the whole class of three-year-olds, instead of some of them being delayed to their next year of life. The East Anglian fishery is for mature fish, and this change is unusual; it has been sustained ever since 1952. Our Scottish colleagues have repeatedly told us of younger fish also becoming more important in northern groups of herring[2]. Evidence that had previously caused us to suspect this advancement of maturity is as follows.

In 1950 an increase of the order of 3–5 times in the density of *Calanus* took place on the plankton stations of the Flamborough Line, and in the same year a sharp increase in the average length of three-year-old herring was observed in a number of North Sea fisheries from the Dogger Bank southward. These increases were sustained in subsequent years, and in 1952, when the first-year class enjoying improved feeding conditions throughout all its life appeared in the fishery, the number of three-year-old fish was nearly doubled.

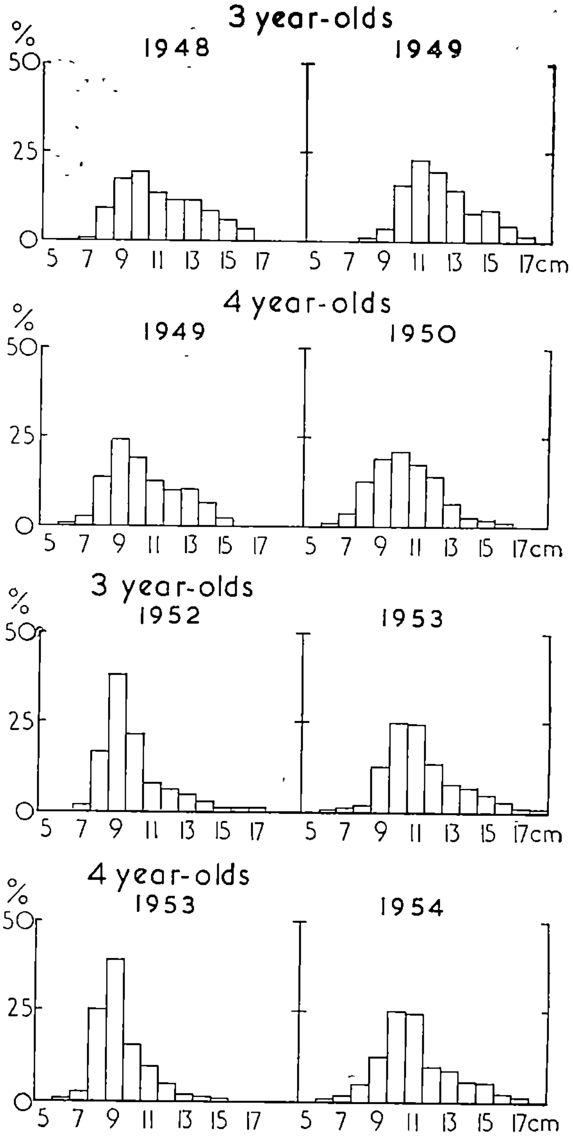

Fig. 1. Distributions of l_1 measurements in the two periods 1948–50 and 1952–54. *a*, Comparison of l_1 distributions of three-year-old fish with that of four-year-olds a year later, in the period 1948–50; *b*, comparison of l_1 distributions of three-year-old fish with that of four-year-olds a year later, in the period 1952–54

The new evidence that full recruitment does take place at three years old is given in Fig. 1. The difference between the l_1 distributions in three-year-olds and that of the subsequent four-year-olds is a well-known phenomenon. Thus, during 1948–50, few small fish with small l_1's reached the fishery as three-year-olds, but came in a year later. The difference is shown clearly in 1949–50 and is discernible, although not so clearly, in 1948–49. During 1952–53 and 1953–54, the l_1 distributions of three-year-olds and the subsequent four-year-olds are almost indistinguishable, and this is more striking in that the difference between the broods is so marked. Thus, after 1952, the first year when the herring would have had better feeding conditions all its life, the l_1 distributions of three-year-olds correspond closely with those of four-year-olds in the following year.

If it is accepted that full recruitment takes place at three years old, it means that the recent changes in the age distribution of the East Anglian herring fishery are partly attributable to natural causes.

Protection from Whole-body X-irradiation afforded to Adult Mice by reducing the Body Temperature

It has been shown that the survival-rate after irradiation of new-born rats[1] and mice[2] may be increased by reducing the body temperature to 2–5° C. at irradiation. A slight reduction in sensitivity of adult rats to whole-body irradiation has also been shown[3] by reduction of their body temperature to 18° or 19° C. The development of a technique for inducing hypothermia in rats by Andjus and Smith[4], and recently extended to mice by Goldzweig and Smith[5], has enabled us to demonstrate considerable protection in adult mice irradiated at a body temperature of 0–1° C.

The mice used were male adults of the 'T' strain bred at the National Institute for Medical Research. The *LD*50 (counting survival at 30 days) for normal mice of this strain is approximately 620 r. of X-rays given to the whole body (Fig. 1) based on observations made on 114 mice. All irradiations were done with 190 kV. X-rays, 6 mA., filtered through 1·5 mm. of copper and 1 mm. of aluminium. The cooled mice were irradiated when all heart and respiratory movements had stopped and the colonic temperature was 0–1° C. The revival was started about five minutes after completion of the irradiation and thirty minutes after the animals' body temperature had reached 1°. Doses of 900 r. (14 mice), 1,200 r. (15 mice) and 1,500 r. (7 mice) resulted in 100 per cent survival at thirty days. The mice lost weight during the first ten days after irradiation; but had all regained their original body weight after twenty-two days. Fig. 2 shows the changes in weight of mice irradiated with 900 r. X-rays at a body temperature of 0–1° C. compared with a non-irradiated group whose body temperature was likewise lowered to 0–1° C. and with another group that were given 900 r. X-rays at normal body temperature.

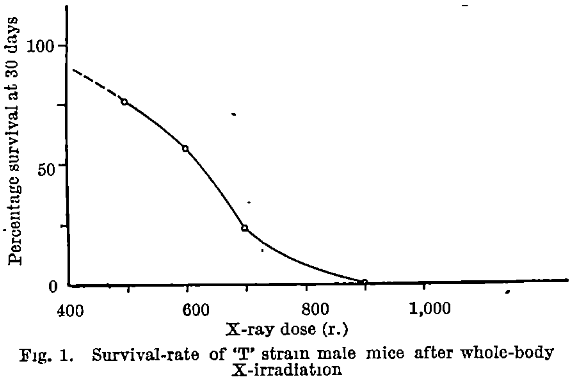

Fig. 1. Survival-rate of 'T' strain male mice after whole-body X-irradiation

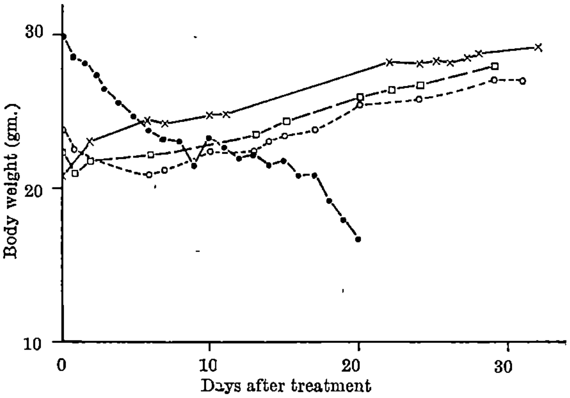

Fig. 2. Weight changes in 'T' strain male mice. ×, Normal controls; □, hypothermic (0–1° C.) controls; ○, 900 r. whole-body X-irradiation during hypothermia (0–1° C.); ●, 900 r. whole-body X-irradiation at normal body temperature

Higher doses of radiation than 1,500 r. at reduced body temperature have not yet been attempted, so the degree of protection given by this treatment has not been established. The dose required to give an *LD*50 at thirty days is, however, clearly more than 2·4 times that required at normal body temperature. The degree of protection is thus greater than that afforded to adult animals by chemical means or by partial anoxia. Nevertheless, since during the lowering of body temperature to 0–1° C. an as yet unknown degree of anoxia, which may be quite severe, is induced, the protection illustrated by these results cannot yet be proportionally assigned to the degree of anoxia on one hand and to the reduced body temperature on the other,

I am indebted to Dr. A. S. Parkes for the supply of the mice, and for facilities in his Division at the National Institute for Medical Research to learn the technique of cooling and reviving animals.

Ultrasonic Absorption and Thermal Conductivity of Muscle

The chance of survival in severe cold of an individual already comatose and with arrested peripheral blood flow will depend, other things being equal, upon the rate at which heat escapes by conduction through skeletal tissue from the central body region. Fat acts as thermal insulation, and is indispensable to Channel swimmers[1]; but men leading a strenuous life, as in the Armed Services, usually have a thin layer only, and their ultimate tolerance of exposure must depend largely upon the thermal conductivity of their muscle tissue. This is extremely difficult to measure on the living individual; but a large number of tests of excised tissue, human and beef, disclosed a range of variation from more than

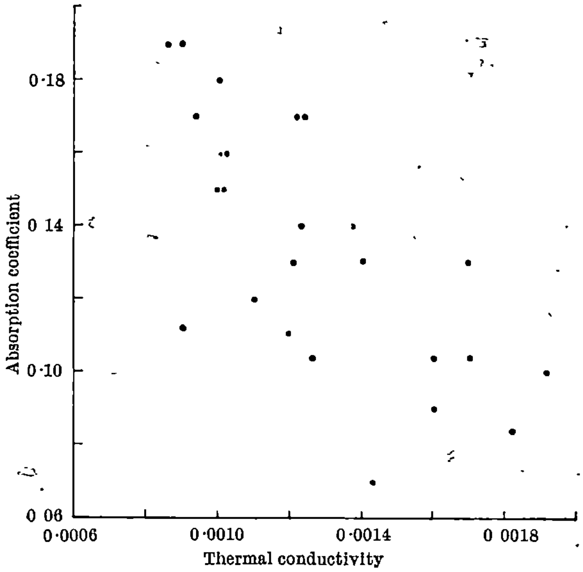

Fig. 1. Absorption of 2½-Mc./s. ultrasonic energy by beef tissue as related to thermal conductivity. Each measurement of absorption is the mean of five points on a piece of tissue 3 in. × 3 in. × 1 in.

double the conductivity of fat (which varies little) down to about the same[2]. If this range is indeed present as between normal living individuals, it would be of practical value to find a method of estimating conductivities on the living, as a help in assessing their suitability for enterprises involving exposure as a hazard.

There are grounds for supposing that the absorption of high-frequency ultrasonic waves by a material such as muscle might vary in the opposite direction to its thermal conductivity. This supposition was tested on fresh beef loin muscle, using a Kelvin and Hughes Mark IV ultrasonic 'flaw detector', which the makers kindly adapted and lent for these experiments. This apparatus causes a quartz-crystal 'probe' to emit every 1/100 sec. a short 2½-Mc. ultrasonic pulse which is received by a second identical probe and displayed on a cathode-ray screen. In the measurement of tissue absorption the probes are set facing one another in a tank of saline, which has negligible absorption. A slab of the tissue to be tested is interposed between the probes, and a fixed voltage (1,000 V.) is applied to the transmitter. The amplitude of the received pulse is adjusted conveniently, and its peak is set to a mark on the screen. The slab of material is then removed, and the voltage reduced to a value giving the same strength of reception. The method serves only for material of closely the same acoustic hardness as the liquid used, otherwise reflexion would occur at the surface of the specimen. This condition is fulfilled very closely for muscle tissue, as is easily verified.

Pieces of freshly killed beef (loin) 3 in. × 3 in. × 1 in. were first tested for absorption at five points; if none departed more than 10 per cent from the mean, the specimen was wiped dry, dipped in oil, and transferred to an apparatus similar to that originally used for conductivity determinations[2,3]. The specimen was in contact on both surfaces with stout copper plates, so that the value for the conductivity was an average of an indefinite character. The results of twenty-five such determinations are shown in Fig. 1, and it is clear that the mean absorption coefficient and the thermal conductivity do in fact vary in inverse ratio for dead excised tissue.

This apparatus will yield reasonable values for the absorption of the calf and thigh muscles of the living individual. It is, however, necessary to develop means for locating precisely the measurements, which vary from centimetre to centimetre, so that an average value can be calculated. This work is in progress.

This investigation is being carried out under consulting contract with the Admiralty (D.R.P.P.). Accommodation for it is provided by St. Bartholomew's Medical School, in Prof. K. J. Franklin's Department, to whom I owe my thanks, as also to Dr. O. G. Edholm (Medical Research Council), who supervised the work.

Stabilization of Xanthine Oxidase Activity by Salicylate

BIOLOGICAL and chemical work with purified xanthine oxidase from cows' milk is handicapped by the loss of its enzymic activity on storage[1,2]. The rate of deterioration, which increases with the degree of purification, is not always the same with different

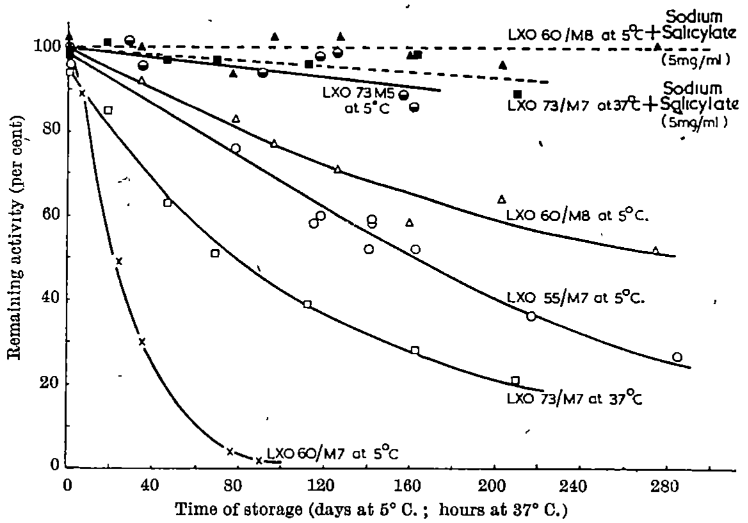

Fig. 1. Xanthine oxidase solutions (see explanation of batch numbers, ref. 10) stored in 1 *M* phosphate buffer, *p*H 6 (except for *LXO* 60/*M*7 and *LXO* 55/*M*7, which were in 0·1 *M* phosphate and 0·2 *M* sodium chloride respectively), at temperatures indicated. Enzyme concentration 0·5–2 per cent. Assays carried out spectrophotometrically (ref. 9)

samples, the cause of such variability being largely unknown so far (Fig. 1).

Stabilization of enzymes could be expected to be brought about by using (*a*) extraneous proteins or polyamides, (*b*) reducing agents, (*c*) chelating compounds and related substances, and (*d*) competitive inhibitors.

While in our case, albumin, polylysine, a di-alkyl analogue of 6.6 nylon (group *a*); glutathione, cysteine, ascorbic acid (group *b*); ethylene diamine tetraacetic acid (versene), 8-hydroxyquinoline sulphonic acid, triethylene tetramine, glyceric acid, glycerine (group *c*) afforded scarcely any significant protection at 37° C. for ten days in *M* phosphate at *p*H 6 (enzyme concentration about 0·5 per cent), sodium salicylate prevented completely any loss of oxidase and dehydrogenase activities[1] at 0–5° C. and almost completely at 37° C. (Fig. 1). Salicylic acid has been reported to act as an inhibitor, though not a very powerful one[3], and our own experiments confirmed that this inhibition was competitive in nature, with $K_i = 1{\cdot}35 \times 10^{-4}\,M$ (spectrophotometric assay at *p*H 8·2, taking $K_s = 5{\cdot}3 \times 10^{-6}\,M$[4]). It is also noteworthy that Keeser[5] reported on 'activation' by sodium salicylate of xanthine oxidase in guinea pig liver after incubation for 2 hr. at 37°; in the light of our findings, this observation may be due to stabilization rather than to activation. Of substances related to salicylic acid (all acids in form of sodium salts), salicylamide, sulphosalicylic acid, salicylaldoxime and gentisic acid showed only slight to moderate effects; but *p*-aminosalicylic acid, acetyl salicylic acid (aspirin) and benzoic acid came near or close to salicylate itself, which remained the best. Our findings may be compared with those of Veitch and McComb[6], who have very recently found a stabilizing effect with *m*-toluic acid on D-amino-acid oxidase.

Salicylate could be removed from the enzyme by dialysis, even after prolonged association. This was proved by the fact that the ratio of ultra-violet absorption at 280 mμ to that at 295 mμ (at which wave-length the salicylate ion has an absorption maximum) returned to the value found with untreated samples, and that $^{14}CO_2H$-labelled salicylic acid was removed almost quantitatively (to about 0·25 mole per mole of total xanthine oxidase) by three consecutive dialysis procedures.

Two points remain to be mentioned: one concerns the low activity established with our xanthine oxidase preparations[1] when using cytochrome-*c* as electron acceptor, which did not increase on adding salicylate, but was inhibited by high concentrations of the reagent; in contrast, 8-hydroxyquinoline augmented this activity slightly, confirming the original observation by Doisy *et al.*[7], who suggested interaction between the iron of the enzyme and the chelating agent. The second point refers to the moderate stabilizing effects of uric acid[8] and 2 : 6-diamino-8-phenyl-purine, the latter a powerful new inhibitor of xanthine oxidase.

Details of these investigations, which include the use of salicylate during the purification process[9], and some evidence for the possible mechanism of loss of activity and stabilization by salicylate will be published elsewhere.

Our thanks are due to Dr. V. C. E. Burnop for the synthesis of labelled salicylic acid, Messrs. D. A. Gilbert and P. G. Avis for the preparation of xanthine oxidase samples, the Research Department of British Nylon Spinners for the nylon analogue, Mr. G. M. Timmis for the purine derivative, and Mrs. K. Tussler for technical assistance.

Presence of Deoxyribonuclease in Silkworm Polyhedral Virus

WORKING on the supposition[1,2] that polyhedral virus would be derived from the deoxyribonuclease-controlling gene, I have now been able to demonstrate the presence of a fairly large amount of deoxyribonuclease in polyhedral crystals.

Larvæ of a pure line, *P*44, were injected with a viral solution and polyhedra isolated in the usual way from surviving diseased individuals. Isolation was, however, carried out under cooling conditions and the last sediment washed with 2 *M* sodium chloride, in order to remove remaining cell debris. 5 mgm. of purified polyhedral virus was dissolved in 0·6 ml. of 0·025 *M* sodium carbonate and centrifuged, and the supernatant was carefully neutralized with hydrochloric acid to *p*H 7·5. The enzymic activity of the polyhedral solution was determined viscosimetrically, using spleen deoxyribonucleic acid as substrate. The velocity constant, *k*, of decomposition expressed as a monomolecular reaction at 35° C. was 0·00105. In the determination of deoxyribonuclease, 0·005 *M* magnesium sulphate was added. The polyhedra showed a very feeble nuclease action in the absence of magnesium ions, and it is assumed that they contain almost no activators. Another solution of the same polyhedral virus preparation was then mixed with 0·02 mgm. of crystalline, pancreatic trypsin and kept at 5° C. for 80 min. The *k*-value was raised to 0·00145 by this treatment. In supplementary tests, I observed, however, that the deoxyribonuclease is somewhat inactivated by trypsin at higher temperature. It seems that the nuclease exists at least partly in a special combination with other proteins in the polyhedron. Deoxyribonuclease was also demonstrated in the polyhedra prepared from strain *P*21.

In one control experiment, deoxyribonuclease of digestive organ-free tissues of host larvæ was estimated in a similar manner. It was found that the nuclease activity of a tissue preparation corresponds to only 5 per cent of that of crystalline polyhedral virus.

Amino-acid Sequence of a Melanophore-stimulating Peptide

A HIGHLY active melanophore-stimulating polypeptide has been isolated from hog posterior pituitary extracts[1]. The amino-acid composition[2] of the active substance (MSH) is consistent with the view that it is an octadecapeptide containing the following amino-acid residues: Arg_1, Asp_2, Glu_2, Gly_2, His_1, Lys_2, Met_1, Phe_1, Pro_3, Ser_1, Try_1, Tyr_1.

In this preliminary communication we wish to report the complete amino-acid sequence of the peptide hormone as deduced from the results of 'stepwise' degradation studies on the intact molecule and from the characterization of peptide fragments isolated from enzymic digests. The methods used in this study may be summarized as follows :

Sequence studies on the intact octadecapeptide. The N-terminal sequence was investigated by a modification[3] of Edman's phenylthiohydantoin method. 2·4 mgm. of the peptide hormone was used for this study, which was carried out as previously described[3,4]. The phenylthiohydantoin derivative of the N-terminal amino-acid was obtained in 85–90 per cent yield and was identified chromatographically as that of aspartic acid. The peptide was afterwards submitted to ten successive applications of the degradation procedure, and the following N-terminal sequence was identified: Asp.Glu.Gly.Pro.Tyr.Lys.Met.Glu.His.(Phe?).

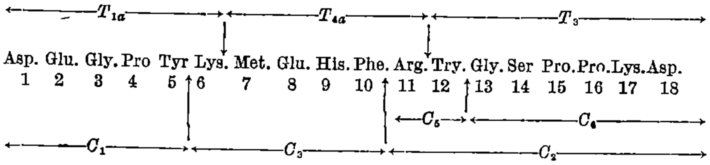
The C-terminal residue was identified as aspartic acid by the carboxypeptidase method[5].

Studies on peptide fragments from enzymic digests

Action of trypsin. The peptide hormone (4·8 mgm.) was treated with trypsin (0·05 mgm.) at *p*H 8·0 and 30° for 30 min. The reaction mixture was submitted to ionophoresis on paper in a pyridine–acetic acid buffer (*p*H 6·5) for 3 hr. at a potential gradient of approximately 40 V./cm., and was resolved into four major and two minor components. The tryptophan and histidine residues were located by means of the Ehrlich and Pauli reagents respectively, and sample portions of each peptide component were separately hydrolysed and analysed for constituent amino-acids by two-dimensional chromatography on paper. The tryptic digest was found to contain the following peptides: T_{1a}, (Asp, Glu, Gly, Lys, Pro, Tyr), T_{1b}, (Asp, Glu, Gly, Pro, Tyr), T_2, (Arg, Asp, Glu_2, Gly, His, Lys, Met, Phe, Pro, Tyr), T_3, (Asp, Gly, Lys, Pro_2, Ser, Try), T_{4a}, (Arg, Glu, His, Met, Phe), T_{4b}, (Arg, Glu, His, Lys, Met, Phe). By the further action of trypsin, T_2 gave equimolar amounts of T_{1a} and T_{4a}, showing that these two peptides are part of the same sequence. T_{1b} and T_{4b} are minor components which, as shown below, are due to chymotrypsin contamination.

Action of chymotrypsin. The hormone (4·8 mgm.) was treated with chymotrypsin (0·05 mgm.) at *p*H 8·0 and 30° for 20 min. The digest was submitted to ionophoresis on paper in a pyridine–acetic acid buffer (*p*H 3·5) for 3 hr. at a potential gradient of 35–40 V./cm.; it was resolved into four major components which were analysed for constituent amino-acids as described above. The chymotryptic digest was found to contain the following peptides: C_1, (Asp, Glu, Gly, Pro, Tyr), C_2, (Arg, Asp, Gly, Lys, Pro_2, Ser, Try), C_3, (Glu, His, Lys, Met, Phe), C_4, (Asp, Glu_2, Gly, His, Lys, Met, Phe, Pro, Tyr). By the further action of chymotrypsin C_4 gave rise to a mixture of C_1 and C_3, indicating that these two peptides belong to the same sequence, and C_2 was split into two new fragments, C_5, (Arg, Try) and C_6, (Asp, Gly, Lys, Pro_2, Ser).

Elucidation of complete amino-acid sequence. Peptides T_{1a}, T_3, T_{4a}, C_1, C_3, C_5 and C_6 were subjected to end-group analysis and sequence studies, from the amino end by means of the Léonis modification[6] of the phenylthiohydantoin method, and from the carboxyl end by means of carboxypeptidase[5]. In this manner the complete structure of each peptide was determined, and the linkages connecting the various fragments ascertained from the overlapping sequences. The complete amino-acid sequence of the melanophore-stimulating hormone is thus established as follows :



The indicated sites of enzymic cleavage are seen to have occurred in accordance with the known specificities of trypsin and chymotrypsin.

The N-terminal decapeptide sequence determined directly on the intact hormone molecule is shown to be in complete agreement with the deduced sequence. Peptides C_1, C_3 and T_3 were also examined by partial acid hydrolysis (12 *N* hydrochloric acid at 37°) and end-group analysis using Sanger's fluorodinitrobenzene reagent[7]. All the di- and tri-peptide fragments which were obtained in this way could be unequivocally located in the indicated sequence.

It may be noted that the sequence Met.Glu.His.Phe.Arg.Try.Gly (positions 7–13) has also been shown to occur in the corticotropins (ACTH, positions 4–10)[8,9]. This observation is of particular interest since it suggests a possible structural basis for the observed intrinsic melanophore-stimulating activity of the corticotropins[8,10], and recalls earlier evidence for the striking relationships between the structure and biological activities of the posterior pituitary hormones oxytocin and vasopressin[11].

Full experimental details of this work will be published elsewhere.

Bacteria in Experiments on rearing Oyster Larvæ

THE larvæ of many species of marine invertebrates have proved difficult to rear in the laboratory; the proper control of many factors is required, including ood, *p*H, temperature and stirring. In particular, onsiderable attention has been given to the requirements of the larvæ of commercial species of lamellibranchs, especially oysters[1–4]. In such work, which has involved long series of rearing experiments, it has been a common experience of workers (in Great Britain and in the United States) that some batches of larvæ fail to develop properly although the conditions provided have been apparently suitable. Some authors have ascribed this result to either the presence or absence of organic substances in the sea water, mplying that such substances are either toxic or ssential to the proper development of the larvæ. This view has been supported by the work of Wilson[5] at Plymouth, which has suggested that different natural waters differ in their value as media for developing *Echinus* larvæ.

Observations which I have made suggest that nsufficient attention has been given to the possible development of bacteria in rearing experiments and heir effect on the larvæ. The purpose of this communication is to direct attention to the very considerable bacterial population which may quickly develop in such experiments. The effect of the presence or absence of the dissolved organic substances may therefore be indirect in that the bacterial population in a larval rearing experiment is very probably dependent on the concentration of the various dissolved organic substances. The concentration of dissolved organic matter in sea water has received omparatively little attention, but it is known to vary considerably[6].

During the summer of 1955, seventeen broods of oyster larvæ were reared under replicate conditions n the laboratory. The experiments were each made n 1 l. of sea water at a temperature of 20° C. Before use, the water was filtered twice through filter candles, he final filtration being through filter candles designed to retain particles more than 1μ in size. The water therefore contained none of the plankton with the exception of a few bacteria. A few ml. of a concentrated *Isochrysis galbana* culture and 300–700 arvæ were added to the water. The additions did not appreciably increase the bacterial population.

The density of the bacteria was observed at ntervals in each experiment by plating diluted amples in triplicate using ZoBell's agar medium No. 2216[7]. The samples were incubated for 48 hr. at 22° C. and the number of developing colonies estimated by, counting ten random microscope fields n each plate. An initial peak, varying between 30,000 and 780,000 bacteria per ml., occurred within three or four days of beginning the experiment. In eight of the seventeen experiments it was more than 200,000. After the first five days the numbers usually declined to lower levels and remained roughly tationary at 1,000 to 10,000 per ml. If there was a marked mortality of larvæ, a second peak occasionally occurred. These densities were not sufficient to make the water appreciably turbid.

Six of the seventeen experiments can be classed as successful as they yielded more than ten spat. n five of them the initial peak was less than 200,000 per ml. and in the sixth it was 300,000 per ml. Thus, five of the six successful experiments occurred in the nine experiments where the initial peak was less than 200,000. Only one successful experiment occurred in the eight experiments where the peak was more than 200,000. These experiments suggest, but do not conclusively demonstrate, that, in this case, the bacteria were influencing the successful development of the larvæ. They do, however, clearly show that the bacterial population in such experiments may be considerably in excess of that occurring in the sea, where usually not more than 1,000 per ml. are found[7]. Recent experiments by Oppenheimer[8] show that dense populations of bacteria may occur in laboratory experiments on hatching marine fish eggs. In this case the percentage hatching was improved when the bacterial population was controlled with antibiotics.

It is clear that, in experiments on rearing marine fish and invertebrate larvæ, the bacterial flora cannot be ignored. Differences which have been observed in the value of different natural waters for rearing larvæ may have their origin in the variation in the size of the bacterial flora which the water can support.

Effect of Superinfection on Phage Sensitivity in Staphylococci

IT has been known for some time that the sensitivity of bacteria to lysis by bacteriophage is conditioned among other things by the presence of lysogenic infection with one or more bacteriophages. Various workers[1–3] have shown that when sensitive cultures were lysogenically infected with typing or even unrelated phages they undergo a change of phage type, the change being a diminution in the number of phages capable of lysing the bacterial cell.

During recent work with staphylococci[4], it was found that one strain could be lysogenically infected and formed a stable system in which every colony was lysogenic; but the culture was not completely immune to the phage in that high titres of phage gave low counts on the lysogenic culture. It is believed that this is due to the presence of a virulent mutant in the phage. The culture employed was N.C.T.C. 8354 with phage N.C.T.C. 8426, the lysogenic system formed being 8354/8426.

Further work was carried out using three other staphylococci, 60, 98 and 105, and three other phages derived from the staphylococci of similar number, that is, 8354 *P* from 8354, 60 *P* from 60 and 105 *P* from 105. These were obtained by filtering the supernatants of overnight broth cultures. The experiments are summarized in Table 1.

It will be seen that when 8354 is rendered lysogenic with 8426 *P* it becomes sensitive to 8354 *P*, 60 *P*

Table 1. PHAGE TITRES PER ML. ON THE GIVEN INDICATORS

Phage	Indicators 98	 8354	 8354/8426
8426 P	10^{10}	10^{10}	10^{6}
8354 P	10^{6}	0	10^{6}
60 P	10^{6}	0	10^{6}
105 P	10^{6}	0	10^{6}

and 105 P. The first-named being its own phage, the problem arose of the stability of the system. It was found that 8354/8426 appeared to contain no 8354 P as judged by two methods. First, indicators for 8354 P showed no plaques when spotted with the supernatant of 8354/8426. Secondly, the supernatant did not plaque on 8354/8426, which would be expected if any 8354 P was present. It appears, therefore, that when 8426 P infects 8354 it displaces the prophage of 8354 P [5] and as a result 8354 is now sensitive to its own phage and in fact to other phages. This would have the effect of changing the typing pattern of the culture in an unexpected way. This work is being extended by testing other systems made with 8426 P.

Artificial Elimination of the *F* Factor in *Bact. coli* K-12

A FEW years ago, Lederberg and his co-workers[1,2] found that in *Bact. coli* K-12 there was a difference in sex-compatibility between the two mating cells, one having a transmissible agent, F, and the other lacking this agent. Hayes[3] demonstrated that these mating types were very stable heritable characters; but the accidental disappearance of the F factor was found by Lederberg *et al.*[1], and by Hayes[4]. The study reported here reveals that it is possible to obtain F^- cells at will from F^+ cells under certain environmental conditions. This phenomenon may be called 'F elimination'. The environmental factor responsible for F elimination is the cobalt or nickel concentration in the medium ($Co(NO_3)_2$, $CoCl_2$, etc.; $Ni(NO_3)_2$, $NiSO_4$, etc.).

The first method of artificial elimination of F factor is called the 'citrate method'. A culture of F^+ cells was inoculated into peptone medium (peptone, 10 gm., and glucose, 2 gm., in 1 litre distilled water), and incubated overnight at 37° C. After 24 hr., 0·15 ml. of 0·4 M cobalt solution was added to 3 ml. of the culture (the final concentration was 20 mM), which was incubated for 24 hr. more. This treated culture was then spread on nutrient agar containing 40 mM of sodium citrate, which was used for detoxification of cobalt, and single colonies grown on the medium were isolated at random. By this procedure, it was found that many colonies were converted into F^-. For example, in the mutant K-12 strain 58–161 and the derived strains from 58–161, 10–30 per cent of the colonies were converted into F^-. However, all the F^- were sensitive to cobalt. The frequency of conversion varies according to the strain of K-12 used.

The second method is called 'resistant isolation' in which cobalt-resistant colonies are selected b serial transfer in peptone medium containing cobal in increasing concentrations. A slow and smoot increase of resistance was observed. Starting fro a concentration of 0·5 mM, in which strains derive from the original K-12 are able to grow, resistan strains tolerating even 20 mM were obtained. Thes resistant strains were plated on nutrient agar containing 20 mM of cobalt, and ten well-grown colonie were isolated at random. In mutant strains 58–16 and Y-40, for example, all ten colonies were F^- whereas in the W-1485 strain, only four colonie were F^-. However, drug resistance and the F character of these strains could be separated; cobalt sensitive strains derived from the resistant were F as before, and cobalt-resistant strains receiving th F factor from F^+ bacteria became F^+ themselves.

The mating behaviour of the F^- strains corresponded to that of the F^- strain described by Hayes[5], and by Lederberg *et al.*[1]. By the cobalt treatment other characteristics, for example, nutritional requirements, sugar fermentation, phage-resistance, lysogenicity, indol formation, shape, Gram staining, an antibiotic resistance were not changed. The F^+ trai is very stable in successive serial passages in ordinar media such as broth, peptone and minimal medium Therefore, in the F^+ clone, the replication of the F factor may be closely concerned with bacteria reproduction.

This hereditary conversion of mating type withi a clone gives rise to the question of the basis of th change and the mechanism by which the F^- strain occurred. There are two well-recognized possibilities (*a*) F elimination may be due to the selection o spontaneous gene mutation; (*b*) it may be induce by the nickel or cobalt in the medium. From th experimental data, the following may be concluded (1) F elimination occurs even in the absence of ce division (in the first method); (2) the occurrence o F elimination is about 100,000 times more frequen than that of other bacterial mutants; (3) F^+ and F strains are equally susceptible to the killing actio of cobalt or nickel as judged by viable counts, an F^- trait is not linked with cobalt or nickel resistance These conclusions seem to exclude possibility (*a*). Th conjecture used for explaining the contradiction i the stability and instability of the F factor is tha it is a non-lytic symbiotic agent, as reported b Cavalli *et al.*[2] and Hayes[4]. It may behave as a cytoplasmic factor and/or as extruded state on to th surface of the F^+ cells at a certain stage of its life cycle. In this state, the sensitivity of the F facto to cobalt or nickel may be greater than that of othe cytoplasmic factors or of nuclear genes.

I wish to express my appreciation of the suggestion and encouragement given by Prof. H. Kikkawa. I a also indebted to Mr. T. Iijima for his advice an criticism during the course of this study.

Carotenoids of Some Brazilian Freshwater Gastropods of the Genus *Pomacea*

VERY few reports are available on the carotenoids of freshwater molluscs[1-3]. The early researches of Kruckenberg (1882) and of MacMunn (1883) on the pigments of *Helix pomatia* revealed the presence of a not well-characterized carotenoid and of some chlorophyll in the liver of this snail. Lönnberg studied extensively the pigments of marine molluscs, and Lederer described two new carotenoids in the marine species *Pectunculus glycymeris* and *Pecten maximus*[4,5].

In a short communication on the lipochromes of *Pila glauca*, a South American freshwater species, Comfort reported that the eggs and the 'uterine gland' were bright red in colour and that the pigment could be easily extracted by crushing the material with water[6]. On partition between 90 per cent methanol and petrol ether most of the pigment appeared in the hypophasic fraction. The intact pigment in formol-fixed embryos showed a single spectral band at 550 mμ. However, the pigments were neither separated nor characterized.

More recently, Cheesman isolated the chromoprotein from the eggs of the water snail *Pomacea canaliculata* (Orb.) and was able to study some of its properties. From extensive chromatographic and spectrographic analysis he showed that the pigment resembles astacene from lobster hypodermis but its identity was not definitely established[7].

Having at our disposal several batches of eggs and of living molluscs belonging to the genus *Pomacea* (*Pomacea*, Perry, is the actual name for the genus *Ampullaria* which is very close to *Pila*[8]. We must remark that *Pila* is not found in Brazil and *Pila glauca* belongs to the genus *Pomacea*[9]), it seemed of interest to investigate the distribution and separation of their pigments. *P. haustrum* and *P. dolioides* lay bright red eggs, and the yolk gland shows the same deep colour, whereas in *P. sordida* the colour is orange-yellow and in *P. decussata* light green. These differences in colour seemed to be related to the diet of these snails, since *P. haustrum* and *P. dolioides* are carnivorous–omnivorous and *P. sordida* is mainly herbivorous. The analysis of these biochromes showed also that the carnivorous species presented almost exclusively xanthophyll esters and free xanthophylls and the herbivorous one predominantly carotene.

The separation of the carotenoids was made by the partition test with immiscible solvents. The distribution of the pigments in the epiphase and hypophase after saponification with 10 per cent alcoholic potassium hydroxide solution is given in Table 1.

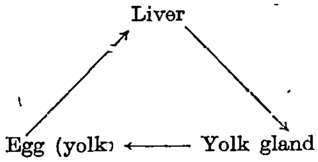
As shown in Table 1, *P. haustrum* and *P. dolioides* contained free xanthophylls and xanthophyll esters and a little carotene. *P. sordida* and *P. decussata* were found to contain only carotene. The epiphasic carotenoids were chromatographed in a magnesium oxide–'Celite' mixture (3 : 1) and the hypophasic in calcium carbonate. Besides β-carotene there has been detected a band corresponding to α-carotene. The hypophasic pigments were shown to be a mixture of three xanthophylls.

Table 1. DISTRIBUTION OF CAROTENOIDS OF SOME SPECIES OF *Pomacea*

Species	Distribution of pigments between 90 per cent methanol and petroleum ether		
	Before saponification	After saponification	Carotenoids characterized
P. haustrum	Mostly epiphasic	Mostly hypophasic	Xanthophyll esters
P. dolioides	Mostly epiphasic	Mostly hypophasic	Xanthophyll esters
P. sordida	Epiphasic	Epiphasic	Carotene
P. decussata	Epiphasic	Epiphasic	Carotene

Purified carotene extract exhibited an absorption maximum at 450 mμ and the predominant hypophasic xanthophyll one at 480–490 mμ. A tentative attempt to modify the carotenoid distribution of the eggs by feeding the herbivorous species a strictly animal diet was unsuccessful. However, the constancy of the carotene in the eggs, liver and yolk gland of these species and the predominance of xanthophyll esters in the carnivores are in accordance with the general rule for other invertebrate animals, that is, that the herbivores store carotene and the carnivores tend to store xanthophylls[3].

The carotenoids existing in the eggs are stored in the liver of the newly hatched young animals, which could be easily shown in the apex of the shell where the liver is located. In the adult female the pigments concentrated in the yolk gland originated probably from the liver. Therefore, the cycle of the carotenoids in these snails may be visualized tentatively as follows:



A study of the distribution and depletion of the liver and yolk gland carotenoids is in progress.

I wish to thank Prof. H. Souza Lopes, of the Department of Zoology, Instituto Oswaldo Cruz, Rio de Janeiro, for the snails used in this work and for help in the dissection and identification of these animals.

Absence of Keratin in Teleost Epidermis

IT has often been stated that the outermost layers of the teleost epidermis are keratinized[1-4]. Young[5] says that, in the trout, ". . . the squamous epithelium of the epidermis provides the animal with a covering of keratin . . .".

During a study of the epidermal structure of teleosts, the following species of fish were examined: *Salmo salar*, *S. trutta*, *Esox lucius*, *Gadus callarias*, *G. virens*, *Molva molva*, *Onos mustelus*, *Tinca tinca*, *Phoxinus phoxinus*, *Anguilla anguilla*, *Conger conger*, *Nerophis lumbriciformis*, *Callionymus lyra*, *Anarrhichas minor*, *Trigla gurnardus*, *Gasterosteus aculeatus*, *Pleuronectes platessa*, *Lepadogaster gouanii* and *Lophius piscatorius*.

Material was fixed in 10 per cent formalin, Bouin and 70 per cent alcohol, embedded in ester-wax and cut at 10μ. Sections were stained with picrocarmine, Papanicolaou's[6] and Mallory's stain. These do not demonstrate any definite keratinized layer of cells, such as is found in higher vertebrates, although in many of the species examined an outer layer of flattened cells, which stains more darkly in hæmatoxylin and eosin than the rest of the epidermis, sometimes occurs.

A further examination was carried out, using the tetrazolium reaction[7], Chèvremont and Frédéric's method[8] and the DDD method[9]. These give no indication of the presence of sulphydryl groups in the epidermis.

It may be concluded from this work that keratin does not normally occur in the epidermis of the species examined; indeed, it is unlikely, from a consideration of the structure of the epidermis of fish in general, that a keratinized layer is ever found.

If it is the case that the outer layers of the epidermis of all bony fishes never contain keratin, the conclusion must be that this characteristic epidermal structural protein was only developed as a protective layer when the vertebrates began to colonize dry land.

I wish to express my sincere thanks to Prof. P. 'Espinasse, in whose Department this work was done, for his helpful advice.

This work was carried out under a Department of Scientific and Industrial Research contract placed with the University of Hull and forms part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Digestion of Nitrogenous Compounds by Ruminants

The utilization of nitrogenous compounds by ruminants is known to be affected by a number of factors peculiar to these animals. Among these, the formation and absorption of ammonia in the rumen have become a subject of considerable interest and importance, as it could perhaps result in a significant wastage of nitrogen in the animal's economy[1–3]. The concentration of ammonia in the rumen can give little indication of the extent of its formation, and, so far as we are aware, no studies have been reported which allow the assessment of just how much of the dietary nitrogen reaches the true stomach under various feeding regimes, and how much is removed at the rumen-level.

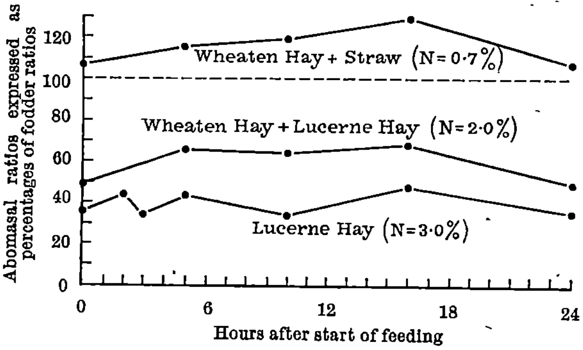

Fig. 1

By using lignin as a marker[4] in the fodder and in the abomasal contents of sheep, we have been able to make such an assessment for a number of diets of widely different protein content. The sheep were fed a regular ration of these diets before being slaughtered at various intervals after feeding. Nitrogen–lignin ratios were determined in the abomasal samples and compared with the ratios in the fodders. For ease of comparison, the ratios in the abomasum can be expressed as percentages of the ratios in the respective fodders. In Fig. 1 the results from three diets are compared in this way. (Details of these and related experiments will be published elsewhere.)

Although relatively few sampling times have as yet been used, the results suggest that they are sufficient to give an approximate measure of the amount of nitrogen reaching the abomasum on each diet. In animals fed on lucerne hay the ratio in the abomasum was maintained at about 40 per cent of the ratio in the fodder, and it must therefore be concluded that the amount of nitrogen reaching the abomasum was equivalent to only 40 per cent of the amount fed. It is to be presumed that much of the remainder was absorbed as ammonia; but it is not known to what extent other soluble nitrogenous compounds were involved. When the ration was a mixture of wheaten hay and lucerne hay, the amount of nitrogen reaching the abomasum was of the order of 60 per cent of the quantity fed.

With the diet of wheaten hay and straw, on the other hand, it appears that more nitrogen reached the abomasum than was present in the fodder. A similar result has been obtained with other low-nitrogen rations of wheaten hay. If the ratio is significantly higher in the abomasum than in the fodder throughout the day the phenomenon may prove to be due to additions of nitrogen to the stomach compartments from the saliva, the blood or the gastric juice. Such additions might be expected to be revealed on feeding low-nitrogen fodders which yield only small amounts of ammonia in the rumen.

Throughout these experiments the ratios have also been determined in the rumen and omasum. The value in the omasum of each sheep was substantially the same as that in the abomasum. So also was the value in the rumen for the greater part of the day; but on diets such as lucerne hay, higher ratios reflected the income of fresh fodder for a short time after feeding.

We consider that extension of this approach may be useful in helping to elucidate some of the many factors which may influence protein digestion in the rumen. For example, we have found that when starch is added to the lucerne ration, the nitrogen–lignin ratio in the abomasum may be raised. Precise measurements of such effects are needed.

We obtained the samples of abomasal contents from slaughtered animals in order to avoid sampling errors as far as possible. It would no doubt be more satisfactory if animals with fistulæ could be employed so that the individual samples for any one feeding cycle would be derived from the same animal.

Evidence of a Neuromuscular Block in Tick Paralysis

Tick paralysis, as reviewed by Abbott[1], is a disease affecting man, cattle, sheep and dogs in many parts of the world. Here, in the Pacific north-west, the causative tick is *Dermacentor andersoni* Stiles. The symptoms are characterized by an ascending flaccid paralysis progressing ultimately to bulbar involvement and death due to respiratory failure. It begins after the female tick has been feeding for some days (usually 4–7) and is reversible on the removal of the tick.

The site of the block producing the paralysis was not known. We believe that the following evidence indicates that it is in the myoneural junction.

In Australia experimental work by Ross[2] involving the intrathecal injection of ground-up tick salivary glands seemed to indicate the spinal cord as the possible site of the paralytic process. However, this work has not been confirmed, and there is presumptive clinical evidence against the spinal cord as the site. First, there are no signs of meningeal irritation in the clinical disease and, secondly, in reported analyses of the cerebrospinal fluid not one showed abnormality that we feel could be attributed to tick paralysis.

In May 1954, one of us (Rose, unpublished data) obtained a response by galvanic stimulation of the thigh muscles of a child aged three who was at the time totally paralysed except for the diaphragm. This indicated that the block was situated somewhere in the nerve-muscle mechanism proximal to the muscle fibres.

In 1955 the following studies were made on laboratory animals.

(1) A 40-lb. mongrel dog was infested with thirty pairs of ticks on April 20 and 22. By April 26 paralysis was almost total except for the bulbar region. After a local skin infiltration of procaine, the fibular nerve was exposed. On electrical stimulation there was no muscle response; but the dog whined. This indicated that there was interruption of the motor but not of the sensory path. This was considered a satisfactory preparation; but general anæsthesia under intravenous sodium nembutal seemed preferable.

(2) A 35-lb. lamb was infested with fifty pairs of ticks on April 27. On the evening of May 4 it was in a state of almost total sub-bulbar paralysis; it was able to struggle slightly. Knee and ankle jerks were absent. It was anæsthetized by an intravenous (jugular) injection of 4 c.c. of sodium nembutal. The fibular nerve was again exposed, and electrically stimulated at one-second intervals. No response was obtained at voltages below 150. There was a weak response to voltages of 150 and higher (Fig. 1,*A*).

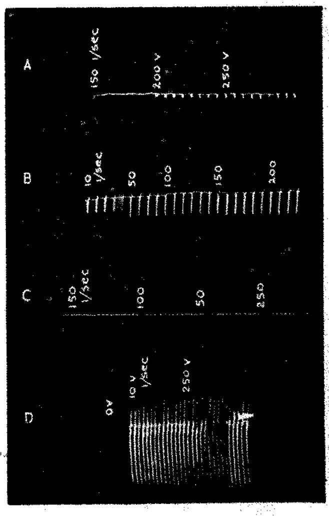

Fig. 1. Kymograph recordings of muscle response to stimulation at one-second intervals of the fibular nerve in paralysed and normal lamb and dog. *A*, Response in partially paralysed lamb at 150, 200 and 250 volts; *B* response in recovered lamb at 10, 50, 100, 150 and 200 volts; *C* response in severely paralysed dog at 150, 100, 50 and 250 volts; *D*, response in recovered dog at 0, 10 and 250 volts

All the ticks were then removed from the lamb. It was normal on May 5, when knee and ankle jerks were present and brisk. An identical anæsthetic was then given and the fibular nerve exposed. The tarsal extensor muscles responded strongly to currents as low as 10 volts (Fig. 1,*B*).

(3) A 30-lb. dog was infested with sixty pairs of ticks on May 9. Sub-bulbar paralysis developed by the evening of May 15. Knee and ankle jerks were absent. After anæsthesia with 6 c.c. of intravenous nembutal the fibular nerve was exposed. Stimulation of the nerve with voltages of up to 250 gave no response other than a minute general twitch of the leg (Fig. 1,*C*).

The control test was performed on the same dog, totally recovered, on the evening of May 17. Identical anæsthesia and preparation were used. Full muscle responses to all voltages down to ten were obtained (Fig. 1,*D*).

Although these experiments were limited in number because of the extreme difficulty of paralysing the experimental animals, we consider that they demonstrate the site of the block producing the paralysis as peripheral to the site of stimulation. This, with the previous evidence that muscle paralysed by a tick is capable of response by contraction to direct stimulation, indicates that the site of the block is at the myoneural junction.

A substance producing a neuromuscular block in a manner similar to that caused by curare is apparently involved. Such an interference with a dynamic biochemical process is consistent with the rapid recovery following removal of the tick. To-day many drugs with this action are being investigated and it may be possible by further experimentation to find more specific similarities between these and the substance produced by the tick. We have not found the paralysis produced by the tick to be lessened by curare antagonists such as prostigmine, and the mode of action, though similar, is probably not identical with that of curare.

Effect of Environmental Temperatures on the Development of Thermoregulatory Mechanisms in Infant Rats

ON the eighteenth day after birth, rats considerably increase their oxygen consumption on exposure to cold[1,2], and their rectal temperature falls at a much slower rate than in younger rats[3]. Hahn, Křeček and Křečková[2], using the method described by Adolph[4], concluded that both chemical and physical thermoregulatory mechanisms develop rapidly between the fourteenth and eighteenth day after birth. Křeček and Martínek[5] demonstrated that in rats raised at 34° C. from birth, thermoregulation develops more slowly, so that on the eighteenth day after birth their rectal temperature falls very rapidly on exposure to cold.

In rats raised at a temperature of 0° C. thermoregulatory mechanisms develop at the same rate as in rats raised at room temperature (20° C.). Their oxygen consumption, however, is increased when measured at 29·5° C. surrounding temperature.

The present communication describes an attempt which has been made to counteract the slowing down of the development of thermoregulatory mechanisms at a high environmental temperature by short exposures to cold.

Rats raised at 34° C. environmental temperature from birth were exposed daily for one hour to 0° C. from the first day after birth up to the eighteenth day. On that day their reaction to cold exposure was studied using the method described by Adolph[4]. Rats were placed in a Bargeton–Krumm-Heller respirometer[6] and their rectal temperature was measured together with their oxygen consumption The thermocouple for measuring rectal temperatures was fixed to the tail and hind legs with adhesive tape. Oxygen consumption and rectal temperature were measured at 29·5° C. for half an hour. Then the surrounding temperature was rapidly lowered to 10° C. and both oxygen consumption and rectal temperature were further measured until the rectal temperature had dropped to 15° C. The time during which rectal temperature dropped to 15° C. after exposure of rats to 10° C. and the oxygen consumption at an environmental temperature of 29·5° C. were taken as indicators. All rats were tested on the eighteenth day after birth.

The rectal temperature of eighteen-day old rats raised at 34° C. and exposed daily for one hour to 0° C. fell at the same rate as in animals raised at room temperature and at a significantly slower rate than in animals raised at 34° C. without interruption (Table 1).

Rats raised at 34° C. and exposed to 0° C. for one hour daily from the fourteenth day up to the eighteenth day, that is, four times altogether, reacted in the same way. Their rectal temperature during the experiment carried out on the eighteenth day after birth dropped at a considerably slower rate than in rats permanently raised at 34° C. The same result was obtained with rats aged eighteen days exposed to 20° C. for one hour daily from birth and otherwise raised at 34° C. (Table 1).

Eighteen-day old rats raised at room temperature up to the fourteenth day after birth and then placed permanently in an environment of 34° C. up to the eighteenth day reacted in the same way as animals raised permanently at 34° C. from birth, that is, their rectal temperature dropped rapidly on exposure to 10° C. during the experimental procedure.

Oxygen consumption measured at a temperature of 29·5° C. during the experiment was significantly higher in rats raised at 0° C. than in all other groups (Table 1).

The large variations in the rate of decrease of rectal temperature are believed to be due to immobilization of the rats during the experimental procedure. The same variations have been observed by other authors[7]. Results indicate that the period between the fourteenth and eighteenth day after birth is decisive for the further development of thermoregulatory mechanisms. This is in agreement with other work[2,8].

It appears that thermoregulatory reactions to cold exposure in rats develop post-natally in close dependence on environmental conditions. The development of adaptation to a certain environmental temperature (0° C., 34° C.) is not identical with the development of thermoregulatory reactions. This is evident from the fact that one hour's exposure to the cold (0° C.) daily suffices to normalize thermoregulatory reactions in eighteen-day old rats raised

Table 1. THE TIME DURING WHICH THE RECTAL TEMPERATURE FALLS TO 15° C. AFTER EXPOSURE OF EIGHTEEN-DAY OLD RATS TO AN ENVIRONMENTAL TEMPERATURE OF 10° C. AND THE OXYGEN CONSUMPTION OF THE SAME RATS AT 29·5° C. ENVIRONMENTAL TEMPERATURE BEFORE EXPOSURE TO COLD

	A	*B**	*C*	*D*	*E*	*F**	*G*

Correlation of Total Body Potassium with Body-Water

THE total potassium content of the human body[1] is of considerable interest from the point of view of physiology and in connexion with the clinical study of certain muscular disorders. Recently it has acquired additional interest because the radioactivity of naturally occurring potassium-40 in the body constitutes the principal 'background' in some 4π-counters used for the measurement of the gamma contamination of human subjects[2–5]. While it has been known for some time that the total potassium varies considerably around a value of 150 gm. in the average adult male[1,6] and while it has been suspected that fat/muscle ratio is the principal determining factor, the correlation has not been clearly demonstrated.

Using the Los Alamos human counter[2], which permits the determination of total body gamma activity to a precision of 5 per cent in less than 5 min., we have measured more than a hundred subjects with body-weights ranging from 40 to 240 lb. The body-water contents of a selected group of these subjects have been determined by the isotope dilution method using tritium tracer[7,8]. The tritium assay of urine specimens was determined by liquid scintillation counting[9,10]. Fat-free weight was estimated from the body-water using the well-known approximation that body-water is 72 per cent of lean body-weight[11,12].

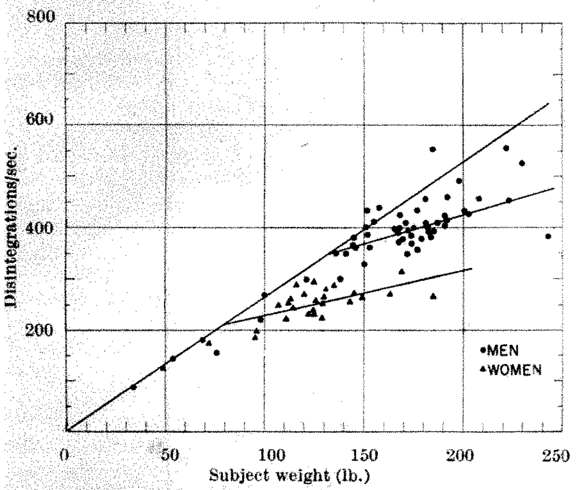

Fig. 1. Natural gamma activity of human subjects

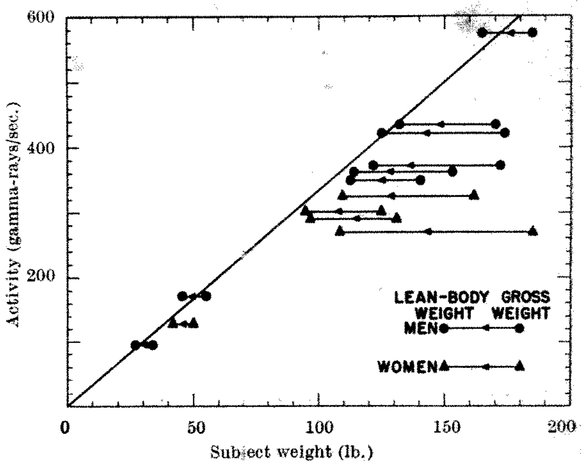

Fig. 2. Natural gamma activity of human subjects in relation to gross and 'fat-free' body-weight

Fig. 1 shows the gamma activity of eighty-one subjects plotted against gross body-weight. The pronounced scatter of the points to the right of a limiting line is clearly evident, as is also the definite separation between male and female subjects. These results indicate that the common practice of expressing total potassium as per cent of gross body-weight[1] will result in a considerable range of values depending on the sex, age, weight, body type and physical activity of the group chosen for measurement.

Fig. 2 shows the results from thirteen selected subjects for which the potassium-40 activity is plotted against estimated fat-free weight as well as against gross weight. (Body-water was not determined on the children; their fat was estimated to be not more than 15 per cent of body-weight.) While some scatter remains, it is obvious that points widely divergent on the original graph are brought close to a common line. This indicates that the amount of fat is the principal factor causing variation in apparent potassium content of the body. (The study of the residual variation is being continued.) The highest natural radioactivity observed is that of a mountain climber (George I. Bell) recently returned from the 1955 Himalayan expedition which attempted Lhotse. At the time of measurement this subject was still below his normal weight as a result of the strenuous activities of the preceding summer.

The determination of body-water should be a valuable adjunct to whole-body counters for normalizing the data to 'fat-free' weight. This will greatly facilitate the evaluation of deviations from the norm resulting from gamma-emitting contaminants or from muscular abnormalities.

The general problem of the *in vivo* determination of gross body composition is an extremely complex one, and the difficulties are clearly defined in the excellent review by Keys and Brozek[11]. The ability of the human counter to determine rapidly and accurately total body potassium, a quantity related to muscle mass, should be of considerable value in the study of this problem.

A more detailed account of these experiments will be published elsewhere. This work was done under the auspices of the Atomic Energy Commission.

An Inactive Thyroid Gland in *Carassius auratus*

Carassius auratus has been subjected to prolonged artificial selection which has established several unusual features. Among these is the inactivity of the thyroid gland. This gland consists of follicles scattered along the anterior region of the ventral aorta; the follicles are typically inactive, with squamous epithelium and abundant colloid.

The activity of the teleostean gland increases with rising environmental temperature, particularly when nearing the upper limit of the viable range, and is indicated by structural change, which is emphasized by treatment with anti-thyroid drugs. Reaction time of the thyroids of *Phoxinus phoxinus* and *Lebistes reticulatus* varies between two and fourteen days according to the season[1,2]. *Carassius auratus* has a temperature-range of 0–41° C.[3]. Exposure to high environmental temperatures (40° C. for one week; 35° C. for three weeks; 30° C. for five weeks; 25° C. for eight weeks) has no effect on the thyroid structure, and it is not affected by exposure to a low temperature. Immersion in anti-thyroid drugs—0·1 per cent thiourea at 30° C. for five weeks; 0·005 per cent *p*-amino-benzoic acid at 25° C. for three weeks; 0·001 per cent potassium thiocyanate at 25° C. for five weeks—is also ineffective. When the thiocyanate treatment is extended to eight weeks, some glands show marked histological change with increased epithelial height and a reduced amount of colloid, although some remain inactive. Higher concentrations of the drugs prove fatal. The experiments were repeated at intervals throughout the year, so the lack of response cannot be due to a period of seasonal inactivity. Compared with the thyroid of *Phoxinus phoxinus* and *Lebistes reticulatus*, the gland of *Carassius auratus* is unusually inactive.

It has been suggested that the increased thyroid activity at high temperatures is responsible for the limiting of the temperature-range by the upper lethal temperature. It seems probable that the wide temperature-range of *Carassius* is associated with the presence of an inactive thyroid gland.

The inability of the gland to concentrate radio-iodine confirms that it is functionally inactive[4]. The thyroid is reported to be extremely sensitive to thyrotropin[5], which suggests that the latter is normally absent.

Biting Times of Parous and Nulliparous *Simulium damnosum*

During dissections of the biting fly *Simulium damnosum* in the Sudan in July 1948[1] it was found that the proportion infected with developing *Onchocerca* worms was nearly twice as high in flies caught before 1 p.m. as in those caught later in the day. Many *S. damnosum* were dissected at Farangbaia in the Tonkolili valley, Sierra Leone, in October and November 1955, and it was noticed that, on some days at least, more flies with a plentiful fat-body (indicating that they were nulliparous) were present in afternoon than in morning catches. It thus appeared that nulliparous flies tend to bite largely in the afternoon; but no exact figures were obtained because the amount of fat-body is very variable and does not always clearly differentiate parous and nulliparous flies.

It was found, however, that the appearance of the ovaries and their ducts, when examined in normal saline, would nearly always serve to distinguish the two conditions. In nulliparous flies the oocytes are closely packed in the ovaries and the oviducts are narrow. In parous flies the oocytes, when small (as they nearly always are in caught flies because *S. damnosum* seldom bites when its eggs are developing), tend to be loosely arranged and the oviducts rather broad and wrinkled. The differences in the oviducts cannot be measured, unlike those in anopheline mosquitoes which have a definite ampulla[2]; but they can generally be quickly detected after a little practice. In the few doubtful cases the condition of the fly can be ascertained by examining other features such as the presence or absence of a meconium and the state of the fat-body.

The ovaries of flies caught biting at Farangbaia between December 14 and 29 were next examined. Out of 179 caught in the mornings 60·9 per cent were found to be parous and 12·3 per cent to contain developing *Onchocerca*. Among 202 flies caught in the afternoons 25·2 per cent were parous and 5·9 per cent contained developing *Onchocerca*.

Evidently a person bitten by the same number of flies in the morning and the afternoon would be more likely to be infected with *Onchocerca* in the former, at least in certain localities at certain seasons. When flies are required for dissection to ascertain the infection-rate it is clearly important to choose a suitable time of day for catching. It is desirable to avoid wasting time in dissecting a lot of nulliparous flies which are unlikely to be infected, and to catch at the same time in different seasons. In the dry season flies may become scarce and difficult to find except in the afternoon. Dissection of flies caught at this time can give a false impression of a seasonal drop in the infection-rate.

It will be interesting to know how general is the tendency of nulliparous flies to bite largely in the afternoon and what is its cause. Perhaps this is linked with the effect, or apparent effect, of physiological condition on the biting times of one or more species of culicine mosquitoes[3-5], biting midges[6] and *Chrysops*[4].

The observations at Farangbaia were part of an entomological survey carried out for the Sierra Leone Development Co., Ltd., and will be reported in detail elsewhere.

Origin of the Common Wild Oat, *Avena fatua* L.

It is generally considered that differentiation of the hexaploid species of oats has resulted primarily from structural changes and gene mutations involving a small group of chromosomes more or less common to all the species. The different species hybridize readily, giving highly fertile progenies, which indicates considerable homology of the chromosomes of any one species with the others. Indeed, it would be difficult to discover a closer chromosome affinity in any group of polyploids than that indicated by Nishiyama[1] for the four hexaploid oat species *Avena byzantina, A. fatua, A. sterilis* and *A. sativa*. With complete affinity between any two species represented as 1·000 and no affinity as 0·000, values obtained by Nishiyama from crosses involving the above-mentioned species ranged from 0·983 to 0·998. More recently, however, cytological studies conducted by Joshi and Howard[2] show that meiotic irregularities are found in fairly high frequencies in hybrids with *A. byzantina* as one parent, which implies that at least some of the corresponding chromosomes of the various species are not completely homologous.

According to early literature, and popular belief, *Avena fatua* is considered to be the wild species which has given rise to our cultivated oat *Avena sativa*, and, similarly, *A. sterilis* to the cultivated red oat *A. byzantina*[3,4]. Recently, however, Coffman[5] has advanced the theory that *A. sterilis* is the more likely progenitor of all the hexaploid species, including *A. fatua*, the nature of origin of which he postulates to be on a parallel with that of the frequently appearing fatuoids in the cultivated species. It is presumed to have arisen early in the line of descent from the wild *A. sterilis* and hence possesses more of the so-called 'wild' characters than do fatuoids appearing in cultivated varieties.

Although the occurrence of fatuoids or 'false wild oats' has been noted frequently in the cultivated species and various hypotheses proposed concerning their mode of origin, we are not aware of any reports of their occurrence in *A. sterilis*. As the appearance of such aberrant types in this species would have a direct bearing on Coffman's theory of origin of *A. fatua*, it is thought that the observations reported below will be of interest.

In an experiment designed to study the effects of irradiation on mutation-rates in wild and cultivated species of oats, two lots of seed of *A. sterilis maxima* containing 10 per cent moisture were exposed to X-ray dosages of 20,000 and 30,000 r. units respectively by the senior author when on a visit to the Iowa State College, Iowa, in 1954. The X_1 generation plants produced from the treated seed were harvested separately, and in 1955 forty plants were grown from each for detailed observations of grain characteristics on a single plant basis in the X_2 generation.

Examination of these plants revealed the presence of a number of mutations in both the 20,000-r. and 30,000-r. treated groups, whereas unirradiated seed from the same original stock and grown under the same conditions gave no aberrant forms. The two predominant mutations were changes in grain colour and mode of floret disjunction, and it is with the latter that the present communication is concerned.

The panicle of normal *Avena sterilis maxima* is equilateral with long, drooping branches bearing very few but extremely large spikelets. The spikelets themselves generally comprise 3–5 fully developed florets with only the lowest and second bearing strongly twisted geniculate awns. Separation of the spikelet from the peduncle is by articulation, a well-defined sucker-mouth at the base of the first grain fitting over the top of the callus pad on the peduncle. The upper florets have no such articulation, and in consequence remain fully attached to the first even after shedding. Forcible separation results in irregular fracture of the rachilla at or near its base. A thick tuft of hairs surrounds the sucker of the basal grain of each spikelet and hairs are also present on the rachilla of the second floret.

Out of a total of 227 lines of irradiated material examined, the aberrant type of floret disjunction was observed in 12 lines, in each of which from one to seven such plants occurred. Although the mutant plants were not observed in detail in the field, it was noted in some cases that they were somewhat lacking in vigour and were erect instead of having the characteristic ascending habit of *A. sterilis maxima*. The panicles were smaller with less than ten spikelets, and the overall dimensions of the spikelet parts were 70–80 per cent of the normal.

The most important and characteristic feature of the mutants was in the morphology of the spikelets

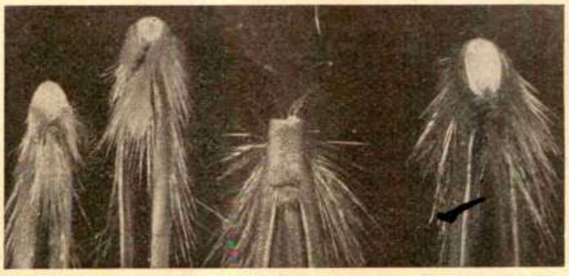

Fig. 1. Bases of first and second grains of *A. sterilis maxima* (left) and of first and second grains of mutant (right) showing difference in mode of floret disjunction

themselves. Instead of the usual number there were up to nine florets with, in some cases, as many as the first six having well-filled grain, and all bearing a geniculate awn on the outer pale except the uppermost one or two which bore only a small straight awn. Each floret was articulated with its neighbour by means of a well-developed and readily separated sucker and callus pad (Fig. 1) exactly similar to that found at the base of the first floret in the wild stock. Hairiness, also, was markedly different in these mutants, a tuft of hairs being present on the base of every floret and on each rachilla segment.

The lines producing these fatuoids could be divided into two groups, namely, those in which the mutants were completely sterile and those in which the fertility was as high as in normal *A. sterilis maxima*. No fatuoids of intermediate fertility were found, neither were sterile and fertile forms present in the same line. Differences between the two groups were slight except for a further reduction in vigour and slightly earlier panicle exsertion in the sterile fatuoids.

Apart from the rather high number of florets formed on each spikelet, these fertile fatuoids closely resemble the true *Avena fatua*, and it is suggested that this latter species could well have arisen through a mutation of this type from *Avena sterilis* as indicated by Coffman. This theory is not in conflict with the evidence from phytogeography, since most authors agree that Asia Minor is the centre of origin of oats, and both Vavilov[6] and Malzew[7] state that *A. fatua* and *A. sterilis* are found growing together in that region.

Spores of the Large Free-living *Amoebae*

IN the course of some experiments on *Amoebae* suggested to me by Dr. P. Couillard of Brussels, I have discovered an easy method of procuring clean spores, newly hatching and developing specimens of the large free-living *Amoebae* (*proteus, lescherae, discoides, kerrii*). These stages are difficult to separate from ordinary stock cultures of the *Amoebae*. Hence, I am frequently asked for spores by teachers whose pupils are interested in the life-history of the large *Amoebae*.

The method is as follows :

Use a rather old culture of mixed ages in which fission division is going on in the full-grown adults. Having removed as much as possible of the 'debris', pipette the *Amoebae* into a vessel containing a dilute solution of inorganic salts (potassium chloride, 0·006 gm., magnesium sulphate, 0·002 gm., double super phosphate, 0·007 gm., 1,000 ml. distilled water). (I use Glasgow tap water, which is very soft, instead of distilled water.)

The change in pH very quickly kills off the ciliates flagellates and the adult *Amoebae* (often in a beautifully expanded condition).

Allow the whole to stand in a warm place for about a week, then examine the bottom of the Petri dish with a No. 7 water immersion lens. Unhatched and hatching spores, as well as young creeping *Amoebae*, will be seen, the latter feeding on the bacteria produced by the decomposition thus set up.

Isotopic Exchange of Oxygen between Free Hydroxyl Radicals and Water

WE have investigated the exchange reaction[1-4]

$$^{16}OH + H_2{}^{18}O \rightarrow H_2{}^{16}O + {}^{18}OH$$

using potassium ozonide KO_3 [5] as a new source of free hydroxyl radicals[6]. Potassium ozonide reacts instantaneously with water enriched in $H_2{}^{18}O$, evolving oxygen according to the reactions :

$$KO_3 + H_2O^* \rightarrow KO^*H + OH + O_2 \quad (1)$$

$$OH + OH \rightarrow H_2O + \tfrac{1}{2}O_2 \quad (2)$$

$$\text{(and partly } OH + OH \rightarrow H_2O_2\text{)}$$

$$OH + H_2O^* \rightarrow OH^* + H_2O \quad (3)$$

$$OH^* + OH^* \rightarrow H_2O^* + \tfrac{1}{2}O_2{}^* \quad (4)$$

The ozonide preparation was of the following composition : KO_3, 89·3 per cent ; KOH, 8·4 per cent ; H_2O (as $KOH.H_2O$), 2·3 per cent. The experiments, in which water containing 1·38 per cent $H_2{}^{18}O$ was used, were carried out in an apparatus equipped with a magnetic stirrer and the means for introducing the potassium ozonide powder in small portions in an atmosphere of nitrogen. The process of adding the ozonide in all lasted 3–5 min. The degree of enrichment of the evolved oxygen was determined mass-spectrometrically, the error in the oxygen-18 content being less than ± 2 per cent of the measured quantity.

The degree of exchange was referred to the total amount of hydroxyl radicals less the amount utilized in the formation of the hydrogen peroxide, the latter being determined by titration with $0 \cdot 1\,N$ potassium permanganate (molecular oxygen and hydrogen peroxide are incapable of rapid exchange with water[4]). Not more than 15 per cent of the hydroxyl radicals were consumed in the formation of the hydrogen peroxide. Table 1 shows the isotopic composition of the oxygen evolved and the degree of exchange.

It can be seen from the table that at 20° and 0° C. the hydroxyl radicals exchange with water to the amount of about 10 per cent. The degree of exchange does not depend upon the pH of the solution ; this confirms that the exchange actually occurs between the hydroxyl radicals and the water, and not between the former and hydroxyl ions.

Considering the relatively low degree of exchange, it must be borne in mind that this reaction competes with the extremely rapid reactions of disproportionation and dimerization of the hydroxyl radicals.

Table 1. ISOTOPIC EXCHANGE OF FREE HYDROXYL RADICALS WITH WATER CONTAINING 1·38 PER CENT $H_2{}^{18}O$

Exp.	Weight of KO_2 sample (mgm.)	Initial solution	pH of final solution	Amount of OH formed (in millimoles)	Amount of oxygen evolved (cm.^{3}) (0·760)	Content of oxygen-18 in the evolved oxygen (atm. per cent)	Degree of isotopic exchange (per cent)

11	165·1	35 cm.^{3} H_2O* + 0·60 gm. H_2SO_4 (0·35 *N* H_2SO_4)	0·5	1·69	45·3	0·226	10·6
							average 10·9 ± 1

† Exp. 12 served as control, showing that on reaction of potassium ozonide with twice-distilled water the oxygen evolved is of normal isotopic composition.

On the basis of experiments on the decomposition of hydrogen peroxide revealing the absence of rapid exchange between hydroxyl and water, it was concluded[3] that diffusion of this radical during the radiolysis of water takes place according to the normal rather than a Grotthus-type mechanism. Our experiments, on the other hand, indicate a very rapid exchange between the hydroxyl radicals and water. Evidence is thus presented for a Grotthus-type interaction of the free hydroxyl radicals with water.

A full account of this work will be published in due course.

Thermal and Photochemical Processes in Polystyrene in the Glassy State

RECENTLY, nylon films irradiated with ultra-violet light[1] have been reported to show a post-effect similar in behaviour to one reported earlier in polystyrene films[2]. It is also suggested that the interpretation advanced for the effect in nylon may be applicable to other polymers. In this note, evidence for different mechanisms in polystyrene is discussed. In nylon, the band that develops during both the irradiation and the post-irradiation periods is centred around 2900 A., while in polystyrene the post-irradiation band is centred around 3400 A. The irradiation spectra for the latter indicate no specific absorption in the region investigated but merely a general increase in absorption. The spectra are shown in Fig. 1, where it is seen that the absorption observed after the post-irradiation period is quite different from that observed immediately after the irradiation period.

A more detailed study of the post-irradiation effecs at 340 mμ shows that this increase of absorption it apparently the result of two independent first-order processes occurring simultaneously. Thus, if the absorption due to this thermal process results from the products of two apparent first-order reactions the relation :

$$[R] = \frac{A_\infty - A}{A_\infty - A_0} = \alpha e^{-k_s t} + \beta e^{-k_f t}$$

should hold, where α and β are the fractions of the total final absorption produced by the slow and fast reactions, respectively, A is the absorption at time t, A_0 at zero time, and A_∞ is the limiting adsorption. In Fig. 2 the data at 70° C. are shown. The curved line for the overall process is seen to be the sum of the two straight lines on the semi-log plot. Results

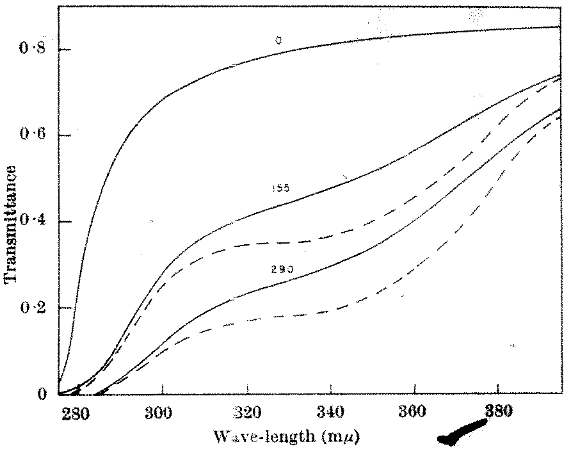

Fig. 1. Effect of radiant energy and subsequent storage on the ultra-violet transmittance of pure polystyrene film. Solid line, exposure for indicated number of hours; dashed line, storage for 290 hr. following indicated exposure time

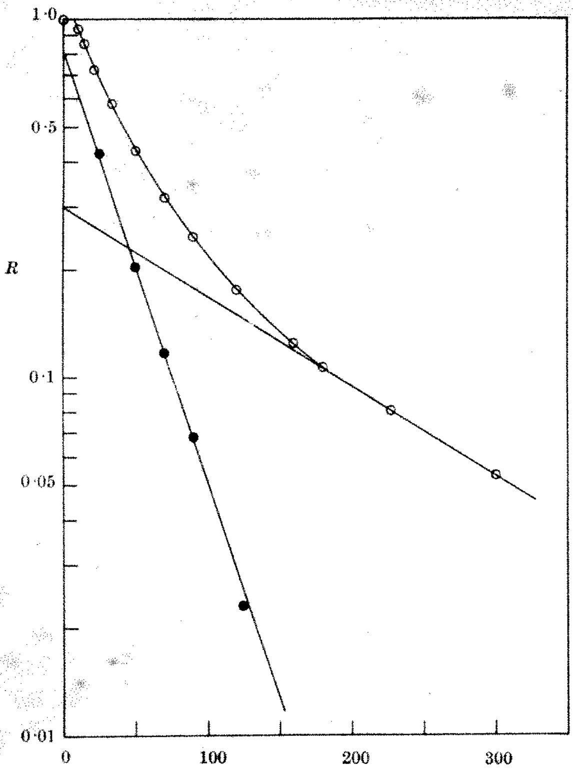

Fig. 2. Semi-log plot of the ratio [R], $(A_\infty - A)/(A_\infty - A_0)$, versus time for the post-irradiation period using polystyrene film at 70° C.

obtained at several temperatures lead to the following expressions for the rate constants : $k_s = 10^{11} e^{-23,500/RT}$ sec.$^{-1}$; and $k_f = 10^{7} e^{-16,400/RT}$ sec.$^{-1}$.

The activation energies are not unreasonable for the decomposition of hydroperoxides or for *cis-trans* isomerization processes.

The work of Lutz and Jordan[3] on the photo *trans-cis* and the thermal *cis-trans* isomerization of benzalacetophenone, a structure which may occur in oxidized polystyrene, led to an investigation of this substance in polystyrene film. Preliminary work with this system indicates similar photo and thermal effects with a shift of the maximum absorbance of benzalacetophenone to longer wave-lengths in the solid state. The rate of the thermal *cis-trans* process is considerably slower than that for the post-irradiation reactions in polystyrene. However, it is known that paramagnetic substances catalyse *cis-trans* reactions, and such substances are undoubtedly present in a partially oxidized polystyrene film.

The work of Ford[1] with irradiated nylon films, in which he postulates a "progressive equilibrium" as the general mechanism for such reciprocal photo-thermal effects in polymers, may give a partial explanation for the observed effects in polystyrene. However, this mechanism is not sufficient to explain the difference in absorption-band shape observed in polystyrene as a result of the post-irradiation effect, nor does it explain the character of the post-irradiation reactions as described above. Also, the intensity of the absorption generated in polystyrene at 3400 A. as a result of exposure to radiant energy has been found in this work to be correlated directly with the intensity of absorption bands in the infra-red region ascribed to carbonyl groups[4].

The existence of peroxy radicals in irradiated polymers as suggested by Ford[1] is not entirely compatible with the observation that the activity of γ-irradiated polymethyl methacrylate for initiating polymerization at 29° C. is reduced by exposing the material to air[5]. Exposure to air, however, increases the activity for initiating polymerization at 70° C. These facts are interpreted to mean that exposure to air destroys immobilized free radicals with the formation of hydroperoxides[5].

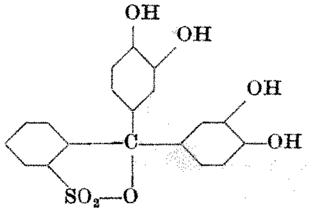
Pyrocatechol Violet as a Detection Reagent for Cations

FOR the purposes of rapid identification of unknown substances on paper chromatograms, both general reagents reacting with a great number of substances irrespective of their nature, and selective reagents allowing a closer characterization of the particular substance play an important part. The most common detection reagents used in paper chromatography and electrophoresis of inorganic cations, which include hydrogen sulphide, 8-hydroxyquinoline and alizarin, react with a large number of cations. Other commonly used reagents belong to the group of selective agents which react only with a definite and rather small number of substances. Most of these reagents react with elements of various valencies and give no indication on the charge of the cation. In the search for a suitable reagent for the detection of thorium on paper electropherograms[1] use has been made of the detection with pyrocatechol violet, which has recently proved successful as an indicator for complexometric titrations since it forms coloured complexes with some cations, especially Bi^{3+} and Th^{4+} [2]. Pyrocatechol violet is a catechol sulphophthalein with formula :



Further study has shown that the indicator can be used for a number of further cations, especially for metals of higher valencies. Best reaction was noted with tri- to hexa-valent metals, such as Al^{III}, Fe^{III}, Sb^{III}, Bi^{III}, Th^{IV}, Zr^{IV}, V^{V}, Cr^{VI}, Mo^{VI}, W^{VI}, which can be shown on the chromatogram down to 0·1 μgm. Some di- and tri-valent metals react conspicuously enough after approximately ten times greater quant-ties have been applied. Some higher-valent amphoteric elements with a prevalent non-metallic character, as, for example, arsenic, react only slightly. Monovalent metals do not react with pyrocatechol violet; of the divalent ones alkaline and rare earths and some further cations are also negative. When comparing the sensitivity of this detection reagent with other general reagents as, for example, hydrogen sulphide or alizarin, pyrocatechol violet has been shown to be more sensitive.

The best method of applying pyrocatechol violet (obtainable from Chemapol, Prague II, Czechoslovakia) on chromatograms or electropherograms is in a 0·05 per cent ethanolic solution by immersion. Reaction of individual cations is strongly dependent on *p*H. It is rather advantageous that the slightly acid reaction on paper is optimal since most solvent systems or electrolytes contain hydrochloric or nitric acid and the paper remains acid following the evaporation of the solvent. Under these conditions, blue or purple spots develop against the yellow background. In alkaline medium the colour of some spots takes a greenish hue against the blue background; at this *p*H some divalent cations (cobalt, nickel) can be detected which react only slightly in acid medium.

Thanks are due to Dr. Simon, of the Institute of Analytical Chemistry, Charles University, Prague, for a gift of some rarer compounds.

Radio Observations of the Planet Venus at a Wave-length of 11 m.

SINCE my first communication on radio signals of 11-m. wave-length from Venus[1], further studies and observations have been made.

Fig. 1 is a record taken May 30, 1956, in which the interferometer lobe pattern due to Venus is very well defined near meridian transit and for an hour or so thereafter. Although better records have been obtained for a few hours, the May 30 record is significant because of the long duration of the Venus signals. Indications due to Venus are discernible from before 11 a.m. E.S.T., when Venus entered the main beam, until nearly 11 p.m. when the signals faded out after Venus set. The wavy line above the chart indicates the lobe pattern of the antenna with the slant lines below showing the positions of the minima. Note that the pattern is shown in rectangular co-ordinates while the actual record is on the more or less slanting co-ordinates of the recorder. The pattern was calculated and checked over much of its extent by the passage of Cygnus *A* through the lobe structure. The minima are not complete nulls since there is a slight unbalance between the two arrays of the interferometer. Ionospheric refraction and scintillation effects are pronounced at 11-m. wave-length. The former effect may be responsible for some variation in the observed positions of the minima, particularly at low angles of elevation. Refraction also presumably accounts for the lag in the time of radio fade-out after the visual setting, this effect being accentuated in the case of Venus because the planet set at an oblique angle with respect to the horizon.

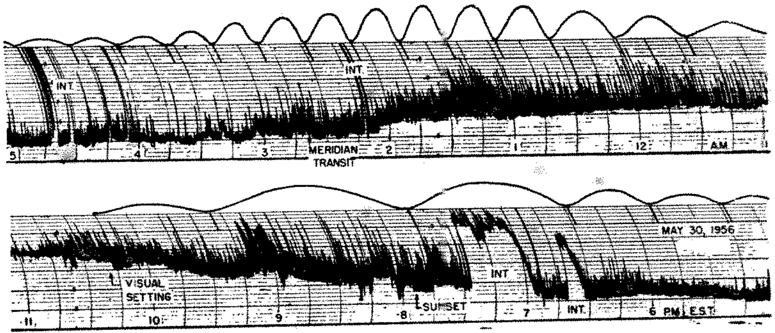

Fig. 1. Record of May 30, 1956, showing the radio noise from Venus obtained with the Ohio State University radio telescope at a wave-length of 11 m. for a period of about 12 hours

Several times on May 30 deflexions were obtained which were presumably interference of some sort (marked *INT*). Some bursts due to local atmospherics were also recorded about noon. However, the minimum in the Venus bursts is readily discernible at 12 noon in spite of this local interference by noting the trend in the shorter spikes in the region. It is to be noted that there are apparently two peaks of activity at about 1.15 and 2.40 p.m. and another pair at about 7.40 and 9.05 p.m., the second pair being 6 h. 25 m. after the first.

It is also to be noted that from 2 to 4 p.m. the base line of the record is elevated in accordance with the lobe pattern, indicating a sufficiently continuous noise to prevent the recorder with its one-quarter second time constant from returning to its normal level. The gradual downward trend in base-level from 11 a.m. to 5 p.m. and upward from 5 to 11 p.m. is due to the galactic background radiation. The small downward jumps in level are presumably due to receiver instabilities.

The Sun was relatively quiet on May 30, and this was the fourth consecutive day on which no important solar flares had been noted. On days of low solar and Venus activity, records are frequently obtained over the entire day which have a recorder pen line that is even narrower and smoother than on the May 30 record at 11 p.m.

Since May 30 further observations have been made, and based on a familiarity with the appearance of the Venus signals it has been possible to go back to the earlier records and recognize that impulsive radio signals from Venus were recorded very probably on at least one occasion in February and with considerable certainty over most of the month of March. No observations were taken during April. As reported earlier, the Venus signals seem to show a peak of intensity at about 90-min. intervals. The March records also show such a peak effect with shorter periods of approximately 20, 39 and 63 min. also in evidence. These periods of more intense activity are plotted as a function of time (E.S.T.) and day of the month in Fig. 2. These observations were made late in the day as the planet passed through the last lobes

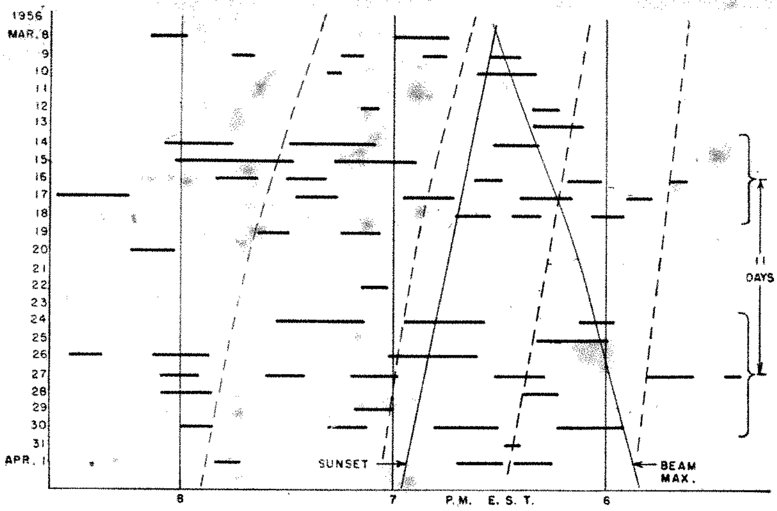

Fig. 2. Periods of peak intensity of radio signals from Venus at 11 m. during March 1956

of the interferometer pattern before setting. These lobes near the horizon are sufficiently wide and the periods of intense Venus signals sufficiently brief for the lobe pattern to have only a minor effect in separating the periods of peak intensity. The lobe minima are shown by dashed lines. The time of sunset and the time when the planet was in the maximum of the antenna primary pattern are also indicated.

The peak periods show a tendency to group around March 16 and 27. Whether this 11-day period is related to the rotation period of the planet is not definite. The peak periods in Fig. 2 also show some tendency to occur progressively earlier during the month. This apparent drift-rate amounts to 5–8 min. per day.

Observations of Potential Evapo-Transpiration

The Nature Conservancy started at the end of 1955 to measure potential evapo-transpiration using the methods devised by C. W. Thornthwaite and his associates[1]. These studies are continuing; but since the first year's results for Achnagoichan in Rothiemurchus, within the Cairngorms Nature Reserve, are of special topical interest, it is worth referring to them briefly at this stage.

1955 was a particularly dry year; but it was surprising that the figures recorded for potential evapo-transpiration reached as high as 6·8 in. in July and 7·1 in. in August, while even the winter months showed in general more than 1 in. These figures are so much higher than would be given by any of the existing empirical formulæ that they are at once open to suspicion. Investigation of every conceivable source of error has so far yielded none which could account for the whole of the discrepancy, and one is driven to conclude that the formulæ fail to give sufficient weighting to one or more factors. It seems likely that wind was underweighted, and this is borne out by the readings in the present winter months, which were comparatively calm, being significantly less than for the previous winter, which was windy. The effects of wind may be augmented by a föhn effect in the intermontane basin of Mid-Strathspey.

A tentative water-budget, constructed from the evapo-transpiration figures and the rainfall, suggests that 1955 ended with a considerable water deficit, which may not be made up before the 1956 vegetative season is under way; this in spite of a very wet December. The calculations are to a large extent borne out by common observation of stream- and well-levels, wilting of plants, etc., where extremes for the century were recorded. It will be of theoretical, as well as practical, interest to see whether the prognostications of water shortage in 1956 are borne out.

On February 8 this year the Advisory Committee on Weather Control of the United States Senate, in a report to the President, put an end to the doubts about the effectiveness of rain-making by seeding clouds with silver iodide. Its demonstration that precipitation had been increased by amounts between 9 and 17 per cent in the Pacific States becomes well worth pondering in Great Britain, where we are liable to shortages such as experienced in 1955, and which we shall probably not be free from in 1956.

Capillary Structure of Coals

A conference on the "Ultrafine Structure of Coals and Cokes"[1] was held in London in 1943; later, Bangham *et al.*[2] proposed a model for coals in which the capillary system was located between closely compacted spherical 'micelles'. More recently, in the laboratories of the British Coal Utilisation Research Association, an extensive investigation of the adsorptive properties of some British coals has been carried out, and has led to a new model of the physical structure of coal. This model may be described briefly as follows.

The ultrafine structure consists of an extensive system of cavities interconnected by a maze of narrow capillary-constrictions. These cavities appear to be flat in shape and are two or three times as wide (about 40–60 A.) as the constrictions. The interconnecting constrictions have a bi-modal distribution of widths, with modal values at 10–20 and 15–30 A. for the coals studied—which included an anthracite, a steam coal, a coking coal, and a free-burning coal. This ultrafine structure, which exhibits molecular sieve properties, accommodates about 95 per cent of the total internal surface area, but only about

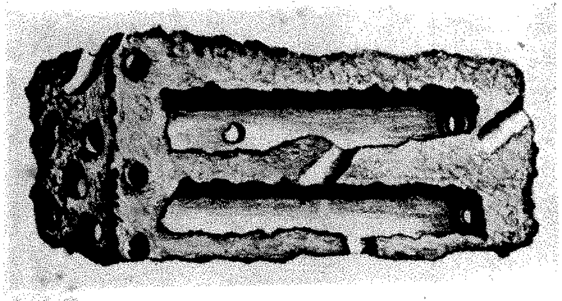

Fig. 1. Model of the constrictions and cavities in coal

50–60 per cent of the total internal free volume of a low rank coal and about 80 per cent of that of a high rank coal. The remainder of the internal free volume is associated with micro-cracks, which are orders of magnitude larger in size. Fig. 1 shows, in model form, this conception of coal structure; the section is taken to show two of the larger cavities (40–60 A. in width) that are reached by molecules permeating the maze of capillaries and constrictions.

The conclusions described above have been obtained from a study of heat of wetting, adsorption and apparent density measurements made with organic adsorbates or dilatometric fluids covering a wide range of molecular configuration, size and chemical properties. The interpretation of these results has required new theoretical treatments to be developed, details of which will be submitted for publication elsewhere.

Heat-Flow from the Earth at Cambridge

In October 1952 work began on a deep boring at Cambridge under the joint sponsorship of the Geological Survey and the Geology Department of the University. Drilling operations ceased in March 1954 at a depth of 860 ft. 3 in., and the hole, lined with aluminium tubes to 588 ft., was left permanently open. The principal object of this undertaking was to gain further information on the underground geology of the Cambridge region, the Palæozoic succession being of particular interest[1,2]. To this end continuous coring was carried on below 176 ft. 6 in. A preliminary description of the borehole was published in 1953[3]. An outline of the lithology is given at the head of Fig. 1.

The construction of a permanent borehole near the Geophysics Laboratory at Cambridge and the availability of a column of rock from the sub-surface formations provided an opportunity of determining the rate of flow of heat from the Earth. The necessary thermal measurements were made during 1954–55 and the value $(1\cdot28\pm0\cdot12)\times10^{-6}$ cal. cm.$^{-2}$ sec.$^{-1}$ obtained.

Temperature measurements were made at levels within the borehole 25 ft. apart, the thermometric device used being a thermistor enclosed in a water-tight brass container. The high (negative) temperature coefficient of resistance of these elements makes them particularly suitable for the measurement of small temperature differences. Calibration was carried out against standardized mercury-in-glass thermometers in a series of thermostats and at the ice-point. A specially designed Wheatstone bridge was used for determining the resistance at each level. Twenty-one sets of readings were taken during the ten months following the completion of drilling, and an examination of the results with regard to the transient thermal phenomena associated with borings[4] indicates that the later readings should approximate closely to the equilibrium temperature distribution in the beds penetrated. The temperature-depth curve shown in the diagram has been constructed from values obtained at least six months after the completion of the boring. The ground temperature of 10·22° C. is the mean of daily measurements made in Cambridge between 1911 and 1940. This information was supplied by the Meteorological Office.

Thermal conductivity measurements were carried out in a divided bar apparatus of the type which has become standard in work on rock specimens[5,6]. Determinations were made at sixteen levels in the Palæozoic rocks, each measurement requiring three carefully prepared rock disks of different thicknesses. The results shown in Fig. 1 have been averaged over 25-ft. intervals to correspond with the temperature data. The large fluctuations of thermal conductivity over small vertical distances reflect the inhomogeneity of the Palæozoic rocks. The cores from this part of the borehole contain a wide variety of lithological types and no uniform section more than a few feet in length was recovered. Density and elastic wave velocity measurements were carried out on specimens from closely spaced levels and the results also exhibited a considerable scatter. Seismic refraction experiments and material obtained from other deep borings indicate that the Palæozoic basement of East Anglia is heterogeneous over a wide area[1,2].

The Mesozoic formations penetrated by the borehole consist predominantly of soft clays, and as the water content of the cores had changed considerably by the time the conductivity experiments were made it was decided to base the conductivity distribution in this section on measurements of external samples. The upper part of the Oxford Clay in East Anglia is particularly homogeneous, and a number of vertically oriented samples were collected in newly exposed quarry workings. The thermal conductivities of these specimens were determined immediately. The mean of four measurements was used for the appropriate part of the conductivity–depth curve shown in Fig. 1.

In calculating the heat-flow of $(1\cdot28\pm0\cdot12)\times10^{-6}$ cal. cm.$^{-2}$ sec.$^{-1}$ only the temperature and thermal conductivity data for the Palæozoic rocks were used. From the mean conductivity of the external samples and the illustrated temperature distribution, a heat-flow of $(1\cdot34\pm0\cdot02 \times 10^{-6}$ cal. cm.$^{-2}$ sec.$^{-1}$ is obtained for the Oxford Clay (179 ft.–338 ft. 2 in.). This is to be regarded as a check on the value quoted earlier.

In 1938 Bullard[7] made thermal measurements in a 100-ft. hole drilled in the Gault near the site of the present boring and deduced a heat-flow of only $0\cdot96\times10^{-6}$ cal. cm.$^{-2}$ sec.$^{-1}$, which is significantly smaller than the values given above for older formations. Between 138 ft. and 169 ft. 6 in. the

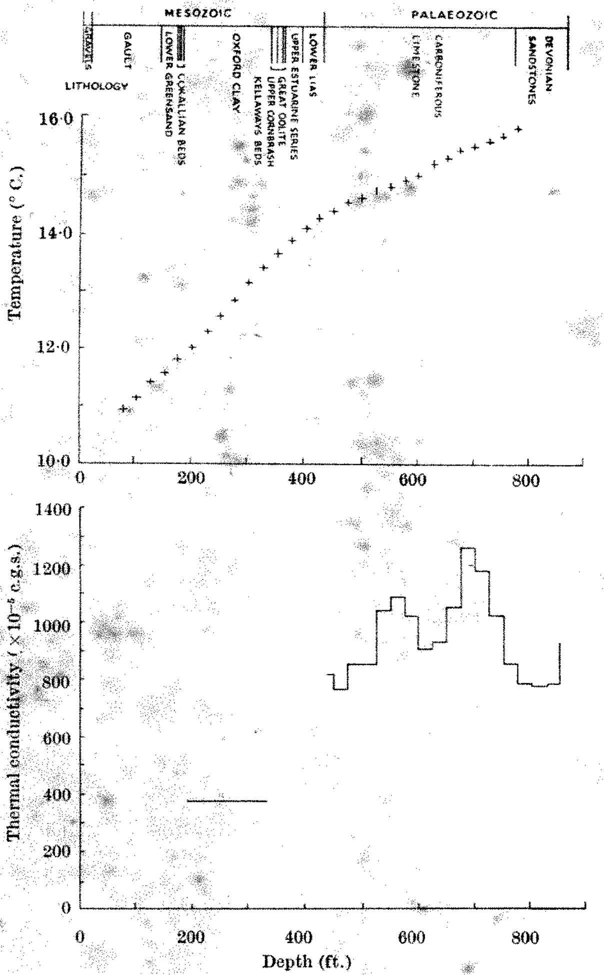

Fig. 1

Cambridge borehole passes through the Lower Greensand, which is the most important source of water supply in the area west of Cambridge. An investigation of water movements in this formation and their possible thermal effects shows that differences in heat-flow between the underlying and overlying beds of the order of magnitude found at Cambridge might be explained by this cause.

Heat-flow measurements near the Earth's surface must be corrected for such effects as climatic changes, igneous activity and rapid denudation in the recent geological past and for topographic inequalities near the point of measurement. Cambridge, however, is situated in a geologically stable area, and the only correction of any importance to be applied is for variations of ground temperature during the past million years or so. Although the Pleistocene glacial deposits of East Anglia have been intensively studied[8] the magnitude of this effect is rather uncertain; but calculations based on Birch's method[9] indicate that the measured heat-flux should be increased by about $0·20 \times 10^{-6}$ cal. cm.$^{-2}$ sec.$^{-1}$. This gives an equilibrium heat-flow of $1·48 \times 10^{-6}$ cal. cm.$^{-2}$ sec.$^{-1}$ at Cambridge.

Seventeen determinations of the geothermal flux have now been made in Britain in nine different areas, and the mean equilibrium value obtained from them is $1·57 \times 10^{-6}$ cal. cm.$^{-2}$ sec.$^{-1}$.

A detailed account of the geophysical work carried out in connexion with the Cambridge borehole is to be published in a forthcoming Bulletin of the Geological Survey.

Electrical Resistivity of Meteorites

SOME attempts have recently been made to interpret the resistivity of the lower part of the Earth's mantle in terms of the semi-conducting properties of silicates[1]. Although it is realized that the mantle may contain a notable proportion of metal phase, as most stony meteorites do, it is generally assumed that the meta phase will occur as isolated grains which will not contribute appreciably to the conductivity.

We have recently measured the resistivity of several stony meteorites containing a variable amount of metal, using a 60-cycle a.c. bridge. Specimens were cut in the shape of square prisms with a cross-section of about 1·7 cm.^{2} and a length of not less than 2·5 cm (Measurements on shorter specimens gave extremely erratic results; for one specimen about 1·3 cm. long the conductivities in two directions at right angles varied by a factor of nearly 10^5.) Repeated measurements in the same direction on the same specimen agreed within 10 per cent; but measurements on different specimens cut from the same stone differed in some cases by nearly one order of magnitude. Results are given in Table 1.

These results show that the resistivity of these meteorites departs by several orders of magnitude from that of the silicate phase, which is about 10^9 moreover, the departure is not proportional to the metal-phase content. There is also some evidence obtained by cutting specimens in different orientations from the same stone, that the material is not isotropic with respect to its resistivity.

If one considers a simple model consisting of parallel silicate and metallic channels with resistivities

Table 1. RESISTIVITY AND AVERAGE METALLIC CROSS-SECTION (β OF STONY METEORITES

Meteorite	Metal phase (%)	Specimen length (cm.)	Resistivity (ohm cm.)	β
Kelley	0·1	2·55	5×10^8	
Arriba I* II III	4·26	2·50 2·55 8·50	$7·9 \times 10^5$ $1·2 \times 10^6$ $1·8 \times 10^5$	$1·3 \times 10^{-11}$ $8·2 \times 10^{-11}$ $5·5 \times 10^{-11}$
Richardson I II	12·15	2·54 2·53	$5·4 \times 10^6$ $1·7 \times 10^6$	$1·8 \times 10^{-11}$ $5·9 \times 10^{-11}$
Rose City I II	17·25	2·50 2·50	14·9 6·9	$6·7 \times 10^{-7}$ $1·4 \times 10^{-6}$
Estacado	31·0	2·61	$7·8 \times 10^3$	$1·3 \times 10^{-9}$

* Roman numerals refer to different specimens cut from the same stone.

ρ_s and ρ_m, respectively, the ratio β of the average metallic cross-section s_m to the total cross-sections of the sample is easily found to be

$$\beta = \frac{s_m}{s} = \frac{(\rho_s/\rho)-1}{(\rho_s/\rho_m)-1}$$

where ρ is the measured resistivity of the sample. For $\rho_s > \rho > \rho_m$ the formula reduces to $\beta = \rho_m/\rho$. The values of β listed in Table 1 were computed for $\rho_m = 10^{-5}$ ohm cm.

It is interesting to see whether the rapid rise in conductivity at depths between 600 and 900 km. inferred by Lahiri and Price[2] could be explained simply by a slight change in the distribution of the metal phase or in the size of the connecting metallic channels. Let us assume that the resistivity drops from 10^6 ohm cm. at a depth of 600 km. to 10^2 at 900 km., while ρ_s and ρ_m remain constant in this range; let us assume further that $\rho_m = 2 \times 10^{-5}$. Since $\rho_s = (1-\beta)/(1-\beta\rho\rho_m^{-1})$ must be positive, β_{600} must be smaller than 2×10^{-11}, and $\rho_s > 10^6$. Thus ρ and ρ_s are both much larger than ρ_m, and $\beta_{900} \approx \rho_m/\rho = 2 \times 10^{-7}$. Both values of β fall within the range of values listed in Table 1 and are quite possible. We conclude that the change in resistivity could be explained by textural changes and, furthermore, that the electrical properties offer no clue as to the precise metal-phase content at those depths.

In the lower part of the mantle, below 900 km., the average resistivity decreases to a value of about 1 ohm cm.[3]. If we take the resistivity of the metal phase to be about 3×10^{-4}, which is close to the generally accepted value of the resistivity in the core, and if we take $\beta = 10^{-6}$, which is probably an upper limit, we find $\rho \approx \rho_s$. It is thus legitimate to consider that the resistivity of the deep mantle is essentially that of the silicate phase. This seems surprising in view of the results reported in Table 1. The difference in behaviour arises from the fact that the ratio of the metallic conductivity to the silicate conductivity under normal conditions is about 10^{13}; a very small metallic cross-section thus produces a large change in conductivity. In the deep mantle, where the ratio is of the order of 10^3, metallic cross-sections of the order of 10^{-6} produce no appreciable effect. It remains possible, of course, that the metallic cross-section may be larger than this figure.

The presence of metallic channels which so largely affect the electrical conductivity under ordinary conditions would have but little effect on the thermal conductivity, as the ratio of the thermal conductivities of the metal and silicates phases is of the order of 10^2–10^3.

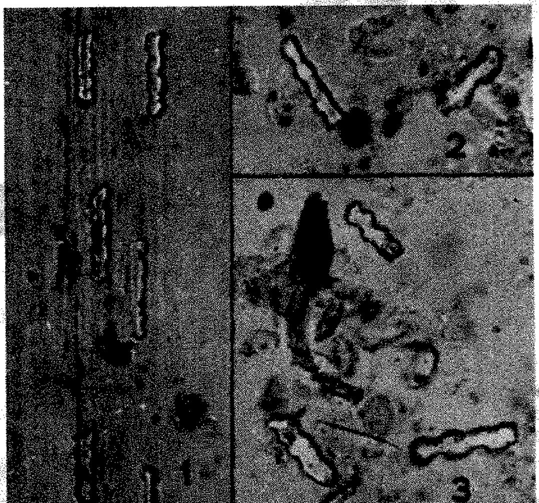
Plant Opal in Soil

In many soils there are small siliceous bodies showing optical isotropy, low refractive index and low density, which identify them with the mineral opal, $SiO_2.nH_2O$[1]. Some are diatoms or diatom fragments. Others are simple or ornamented rods, tubes, hooks, etc., resembling the opaline bodies which are components of many plants[2-4]. Van Rummelen[5] has figured rods and tubes of isotropic silica from Indonesian soils and has suggested that such particles are always of inorganic origin, being deposited around root hairs which afterwards decay or in soil capillaries. Oosov[6] has observed biologically accumulated silica in Russian soils.

Studies now being carried out in Anglesey on the shapes and sizes of opaline bodies in the soil and in the vegetation leave little doubt that here most of the soil opal has been formed in living plants. An example of the degree of matching is given in the accompanying photomicrographs. Fig. 1 shows opaline bodies in a leaf of *Agrostis tenuis* treated with chromic acid and Figs. 2 and 3 depict objects similar in optical properties, shape and size in the silt fraction from a soil on which this grass forms the major part of the sward. It is not suggested that microscopic examination of these bodies in a soil makes it possible to name the grasses which formed them; but it should permit one to indicate what groups are or have been present. In some places the soil has yielded bodies which match those obtained by the chromic acid treatment of *Equisetum* sp. present on the site. Opaline bodies from grass are abundant in the dung of grazing animals, and many must reach the soil by this means.



Figs. 1-3. Opaline bodies in *Agrostis* leaf and in soil (× 372)

The silt of a swamp deposit normally covered by beach sand in Lligwy Bay, Anglesey (but exposed occasionally, for example, in 1912 and 1953), has yielded an abundance of opaline bodies which are now being investigated.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, July 16

British Psychological Society (in the Psychology Department, Birkbeck College, Malet Street, London, W.C.1), at 8 p.m.—Dr. E. Colin Cherry and Mr. B. McA. Sayers: "Some Experiments on the Total Suppression of Stammering"; Mrs. Pauline M. Marland: "The Shadowing Technique for the Treatment of Stammering—a Progress Report".

Thursday, July 19

University of London (at the Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E.5), at 5 p.m.—Mr. K. A. C. Elliott (U.S.A.): "Metabolism of Human Cerebral Tissues"*.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Research Student in Metallurgy, Engineering (civil, mechanical or electrical) or Chemical Engineering—The Registrar, University College, Singleton Park, Swansea (July 17).

Chief Chemist in the Rivers Pollution Prevention and Fisheries Department—The Chief Inspector, Kent River Board, College Avenue, Maidstone, quoting CC/T (July 20).

Assistant Lecturer in Botany—The Secretary, The University, Exeter (July 21).

Master (preferably young bachelor) to teach Mathematics throughout the school to scholarship level—The Headmaster, West Buckland School, Barnstaple, Devon (July 21).

Research Fellow (chemist or biochemist with research experience in protein or polysaccharide chemistry), to work in collaboration with Dr. D. A. Hall of the Nuffield Gerontological Unit in the Department of Medicine—The Registrar, The University, Leeds 2 (July 27).

Senior Library Assistant (with a degree or professional library qualifications and previous library experience)—The Librarian, University College, Gower Street, London, W.C.1 (July 28).

Assistant Experimental Officer (with a pass degree in chemistry or equivalent, and preferably botanical training) to help with the biochemical study of tuberous *Solanums*—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts (July 31).

Chief (with an honours degree in agriculture or equivalent, long practical experience in all branches of agricultural science, and considerable experience in research work and administration) of the Agricultural Research Division, Ministry of Agriculture, Sudan Government—The Chargé d'Affaires, Sudan Diplomatic Mission in London, Sudan House, Cleveland Row, St. James's, London, S.W.1, quoting "Chief Research Division 4/439" (July 31).

Lecturer (with experience in grassland husbandry) in Agriculture (Crop Husbandry)—The Secretary, The University, Edinburgh (July 31).

Principal Lecturer (with a first- or second-class honours degree in mathematics, and experience of teaching pure and applied mathematics) in Mathematics at the Royal Naval College, Greenwich—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting Ref. No. 4610/56/1 (July 31).

Principal (qualified to direct a major technical college concerned with full-time and part-time education in engineering to degree standard and other technologies, including postgraduate studies and research)—The Clerk to the Governing Body, Northampton Polytechnic, London, E.C.1 (July 31).

Scientific Officer (with a good honours degree in botany or agricultural botany, and preferably an interest in fruit culture and plant physiology) in the Pomology Department (Ref. POM/2); and a Scientific Officer or Experimental Officer (preferably graduate, with a knowledge of, and an interest in, work on insect pests of soft fruits) in the Entomology Section of the Plant Pathology Department (Ref. PP/2)—The Secretary, Scottish Horticultural Research Institute, Mylnefield, Invergowrie, by Dundee (July 31).

Lecturer in Geology—The Head of the Department of Geology, Imperial College of Science and Technology, South Kensington, London, S.W.7 (August 4).

Assistant (with a degree in science, preferably honours) in the Chemistry Department at Auchincruive, Ayr, for work relating to the spectrographic analysis of agricultural materials—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (August 10).

Dewar Research Fellow in Radiation Chemistry—The Secretary, The University, Edinburgh (August 11).

Professor of Agricultural Botany—The Registrar, The University, Reading (August 20).

Professor of Psychology—The Registrar, The University Reading (August 24).

Senior Lecturer (with experience in research and teaching in one of the following fields: mycology, algology or anatomy) in Botany at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 29).

Chair of Mathematics—The Registrar, University College of North Staffordshire, Keele, Staffs (August 31).

Lecturer in the Ramsay Memorial Laboratory of Chemical Engineering—The Secretary, University College, Gower Street, London, W.C.1 (September 1).

Assistant (preferably with a biological degree and bibliographical experience, and a knowledge of Spanish, Portuguese or Italian) for the preparation of a journal comprising an annual record of the contents of entomological publications—Commonwealth Institute of Entomology, 56 Queen's Gate, London, S.W.7.

Chemists (2) (with at least a second-class honours degree and two years postgraduate experience) with the Colonial Insecticide Research Unit, Arusha, Tanganyika, to supervise chemical aspects of research into the control of insect pests—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.195/196/06.

Lecturer (Grade II) in Physical Metallurgy—The Registrar, The University, Birmingham 15.

Lecturer in Engineering, and a Lecturer in Mathematics—The President, Mount Allison University, Sackville, New Brunswick, Canada.

Lecturer (with a good engineering degree and some experience in industry and research) in Mechanical Engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London E.1.

Mycologist, to take charge of the work on plant diseases in relation to crop varieties—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Physicist or Engineer (with an appropriate degree), for basic research on crop drying and other problems in electro-agriculture—Head of the Rural Electrification Department, Electrical Research Association Field Station, Shinfield Green, Reading.

Senior Lecturer (graduate in physics or chemical engineering and industrial experience of food processing operations)—The Registrar, National College of Food Technology, Cranwood Street, City Road, London, E.C.1.

Senior Lecturer in Physiology and Pharmacology at the Technical College, Bradford—The Director of Education, Town Hall, Bradford.

DIFCO

BACTO-CEPHALIN CHOLESTEROL ANTIGEN

For Hanger Flocculation Test

An approved and stable reagent for use in the Hanger Flocculation Tests to determine disturbance of liver function. Available in packages of six units, each unit equivalent to 150 ml. final test antigen.

Hanger: J. Clin. Invest. **18**:261:1939.

BACTO-THROMBOPLASTIN

For Prothrombin Determination

A stabilized rabbit brain substance for use in determining the Prothrombin Time of Blood. Bacto-Thromboplastin is applicable to the procedures described by Quick, Link-Shapiro, Smith, et al., Kato and Poncher, and other tests requiring a potent thromboplastin. Each box of Bacto-Thromboplastin contains 6 ampoules, sufficient for 210 Quick determinations or 420 Link-Shapiro determinations.

A CENTRE FOR GEOGRAPHICAL RESEARCH

IN his presidential address at the recent annual meeting of the Royal Geographical Society, General Sir James Marshall-Cornwall made a plea that the Society should become the focal point of geographical research in Britain. It is an idea which should be sympathetically received by the numerous departments of geography which now flourish in all our universities, and not least by the geographers in the different schools of the University of London.

The Society is, of course, generally known not for its contributions to research and education, not even for its services to the public as the principal centre of geographical information in Britain, but for its sponsorship of exploration, of a scientific as well as of an adventurous kind. But its efforts to promote research and education are at least as important a part of its long and distinguished history, especially its efforts to establish geography as an academic discipline in the universities throughout Britain. By the middle of the nineteenth century, the fortunes of geography, which had steadily declined in Britain since Elizabethan days, were at a low ebb. In 1848, the Prince Consort, newly appointed chancellor of the University of Cambridge, strongly deplored the fact that there was no provision for the teaching of geography to undergraduates of the University. The position at Oxford at that time was no better. An attempt had been made there in 1857 to found a Waynflete professorship of geography. But it was soon abandoned. Then the Society, led by a redoubtable president, the late Sir Clements Markham, stepped in and achieved remarkable success. With its help, financial and moral, a readership was founded at Oxford in 1887, and the year 1899 saw the establishment there of the first Department of Geography in Britain. Two years earlier, again with the Society's help, a lectureship in geography at Cambridge, dating from 1888, was converted into a readership, and a University Board of Studies in Geography, the embryo of the future Department, was set up in 1903.

In that year, according to the late Dr. Hugh Robert Mill, the Royal Geographical Society set up its own Research Department to co-ordinate lectures on technical subjects. This also served as a centre from which attention might be directed to problems of geographical research which the supervising Research Committee felt were of particular importance*. Land utilization, coastal morphology, soil erosion and other problems of the arid and torrid zones, microclimatology, the geographical pattern of disease, were some of the fields in which the Society set out, in those early days, to promote research. The contribution of the Society's own Research Department and Committee is not easy to estimate. But its full list of subjects to be studied covers most of the main lines of advance in geographical research since that time. Meanwhile, the Society's efforts to stimulate geographical education in the universities continued unabated. Between 1887 and 1924, it has been calculated*, more than £20,000 was contributed from its funds towards the establishment of geography as an enduring part of university education in Britain.

To-day, the Society is already, in some respects, on the way to becoming a centre of geographical research of the kind its president has in mind. Its excellent geographical library is predominantly used, not, as is sometimes supposed, by the dilettante reader of travellers' tales, but by undergraduate and postgraduate students. Its technical lectures and discussions provide a forum, not only for university geographers, but also for those working in the more specialized branches of science who are concerned with geographical aspects or the application of geographical techniques. Geography, so it seems, is essentially a co-ordinating, a bridging, study involving an appreciation and an interpretation of relationships against the physical background. To geographers the water-tight department should be anathema. Close contact must therefore be maintained by them with these specialist branches, since it is the latter which provide the source of material for geographical synthesis.

In these and in other ways, as in the continuous association which is maintained with geographical research workers abroad, as in its research publications and production of special maps, and in its promotion of field-work by expeditions, the Society is already fulfilling some of the functions of a centre of geographical research.

How else then could the Society fulfil the role outlined by General Sir James Marshall-Cornwall in his presidential address. With so much achieved, with so many facilities available, might not such a centre now be formally established in the Society as an institute of geographical research, associated perhaps with the University of London, but not, of course, confined to it? An institute of this kind, administered and financed jointly by the Society and the University, was proposed many years ago by the late Sir Halford Mackinder and outline plans were printed. There are parallels, indeed, more or less, in some of the existing institutes of the University; in the Institute of Commonwealth Studies which has some association with Chatham House; in the Institute of Classical Studies which is linked to, and uses the library of, the Greek and Roman Societies; in the Institute of Historical Research. The several geographical departments of the University are widely scattered over London. The scope of geography is diffuse; its need for a central point of contact with cognate branches of learning is very marked. The emphasis given to different aspects of geography by the different schools, both inside and outside London, varies considerably. These are all considerations which suggest that geography is a field of study which would derive special benefit from the establishment of a central institute to promote and co-ordinate advanced studies and research.

---

* "The Record of the Royal Geographical Society, 1830–1930", p. 147. (London, 1930.)

* "Geography as a Humane Study", p. 6. An inaugural lecture by Prof. E. W. Gilbert. (Oxford, 1955.)

There were rumours some years ago that plans for just such a geographical institute—following up, no doubt, Mackinder's earlier plans—were to be considered by the University of London. If so, then the prospect of obtaining a suitable building and of forming afresh a library and map collection could scarcely have been encouraging. Nor would the project be easy to justify while there exists in London, in the Royal Geographical Society, the nucleus of such an institute with ample buildings of its own, with land adjacent for extensions, with an excellent specialized library, and a map collection unrivalled in Britain, and for that matter in Western Europe. It would surely seem better sense to make greater use of the facilities already available in the Society, and to adapt them as necessary for academic purposes, than to attempt to start afresh.

There should be no insuperable problem in supplying the other services which an institute of geographical studies should provide. With the co-operation of members of the geographical departments of the different schools of the University, seminars for advanced students could be held and instruction and supervision arranged. For a number of years towards the end of the nineteenth century, a studentship for geographical research was jointly offered by the Society and the University of Oxford. Once the Society had received formal academic recognition—and this would be the first important step—help might well be forthcoming from one of the great foundations towards the establishment of similar postgraduate studentships attached to the Society's research institute, including provision for field-work abroad. The administration of the institute might, it is true, pose some awkward problems. The Society is almost entirely financed from the subscriptions of its members, to whom it must have special obligations. But this again should not prove an insuperable obstacle. Some form of a joint committee with the University would probably provide an answer.

The Royal Geographical Society has, through its president, shown an evident desire to play a greater part in the promotion of geographical research by offering to include in its establishment a centre of advanced studies. It is a function for which in many ways it is ideally suited, and one for which it already has many material advantages. The Society has, implicitly at any rate, extended the invitation. It is now for the university geographers in London and elsewhere to respond, at least to the extent of showing signs of willingness to examine the invitation carefully.

CLEVELAND ABBE: A PIONEER AMERICAN METEOROLOGIST

Professor Abbe and the Isobars

The Story of Cleveland Abbe, America's First Weatherman. By Truman Abbe. Pp. xi+259+14 plates. (New York: Vantage Press, Inc., 1955.) 3.50 dollars.

CLEVELAND ABBE (1838–1916) has an honoured name in the history of meteorology as the man who, more than any other, created the United States Weather Bureau. This book, written by his son, the late Dr. Truman Abbe, gives the story of his life and recounts some of his struggles to bring into being and maintain an official weather service worthy of the name.

Abbe came of New England farming stock. As a young man, he studied astronomy at Ann Arbor and at Cambridge, Mass., after which he spent two years in Russia working under Otto Struve at Pulkova Observatory. In 1867 he returned to America, and in 1868 was appointed director of the dilapidated astronomical observatory at Cincinnati. The next year he began to publish daily weather reports under a loosely knit sponsorship of the Cincinnati Chamber of Commerce and the Western Union Telegraph Company. His first published forecast (he usually called them 'probabilities') was produced on September 1, 1869, and in his diary for the same day he wrote: "First prognostication. A Doubt and a Failure". The venture soon came to an end for lack of support, but it led to an Act of Congress providing for the use of the Signal Corps of the Army for the organization of a public weather service, in which Abbe filled the dual role of chief forecaster and what we should now call 'director of research'. The Signal Corps at that time, however, was not sympathetic to scientific work, and Abbe's enthusiasm and unfailing good nature often must have been strained to the utmost in his efforts to build up an efficient service. In 1891 Congress relieved the Signal Corps of its unwelcome task and set up the United States Weather Bureau in the Department of Agriculture, with Abbe as "professor of meteorology".

The new venture began well, but quickly ran into trouble. When, in 1893, the government changed hands, Abbe and others of the scientific staff were reduced in rank and pay, on the official but scarcely credible grounds of incompetence. From the account given in the present book this seems to have been entirely an act of political vengeance against men who had the misfortune to be appointed by the opposition party. Abbe did not regain his position and salary until several years later, when a new chief of the Bureau was appointed; but it is evident that throughout most of his long association with the Weather Bureau he was regarded as its principal scientific authority. Later, he travelled extensively, writing long letters home, and he did not resign his post with the Weather Bureau until a few months before his death, when he was nearly eighty years of age.

Abbe wrote voluminously and for many years was editor of the *Monthly Weather Review*. In addition, he published a noteworthy collection of translations of papers on dynamic meteorology entitled "The Mechanics of the Earth's Atmosphere", as well as books on instruments, forecasting, and the relation between climate and crops. It is somewhat difficult to assess the true scientific value of this large output, which is scattered over so many periodicals; but it is probably fair to say that, although not a very original worker, he did as much as any man to bring the science of his day into official meteorology. Some extracts from his writings are given in this volume, and one cannot fail to be impressed by their integrity and clarity. His article on rain-making and long-range forecasting, for example, although published in the *Monthly Weather Review* as long ago as 1903, can still be read with profit. His talents were widely recognized in his lifetime, and probably nothing pleased him as much as the award of the Symons' Memorial Medal by the Royal Meteorological Society in 1912.

The present volume is not in any sense an 'official' biography, and it attempts no objective evaluation of his work as a meteorologist—a wise decision, seeing that the author was his son and a medical practitioner. It is little more than a collection of intimate sketches and anecdotes, loosely strung together and filled out with extracts from his letters and accounts of family matters, much of which is now rather dull reading.

But the impression left on the reader is clear enough—that of a kindly, deeply religious man who, by his integrity, enthusiasm and secure knowledge of the physics of his day, helped to lay the foundations of a great scientific institution. Even if his work had not the imprint of genius, like that of Bjerknes or W. H. Dines, his contribution to meteorology was exactly what was needed for the time. When he began, meteorology was little more than folk-lore; when he died, it had become a science.

O. G. SUTTON

PROF. W. A. HEISKANEN: SIXTIETH BIRTHDAY VOLUME

Professori Weikko A. Heiskaselle hänen 60-vuotispäivänään omistettu juhlajulkaisu

Veröffentlichungen des Finnischen Geodätischen Institutes. Nr. 46. Pp. 214. (Helsinki: Suomen Geodeettisen Laitoksen Julkaisuja, 1955.) n.p.

PROF. W. A. HEISKANEN is well known among geodesists and geophysicists for his contributions to the study of isostasy and as director of the International Isostatic Institute of the International Union of Geodesy and Geophysics and research professor at the Mapping and Charting Institute of the University of Ohio; his many friends will be pleased that the Finnish Geodetic Institute has commemorated his sixtieth birthday by the publication of this volume of essays. The book is in two parts, the second of which, comprising five papers on the results of the 1945 solar eclipse expedition of the Finnish Geodetic Institute, will be read by all interested in the use of eclipse observations for geodetic position measurements.

Among the eighteen commemorative essays in the first part of the volume, four have a distinctively Finnish character. V. Erola describes the development of air survey in Finland, and K. G. Lofström discusses in detail the method of stereo-photographic triangulation, peculiar to Finland, in which the horizon is photographed by two horizontal cameras to determine the tilts of the vertical camera by which the ground is photographed; Errki Kääriäinen compares two different methods for calculating the uplift of the land from the results of the two precise geodetic levellings of Finland, and Heikki Tuori reviews the technical delimitation of territorial waters with reference to the particular problems of the Finnish coastline. The paper by Tauno Honkasalo, in which he describes some tests of height measurements with aneroid barometers with a mean error of 1·6 m., will be useful to others who have to make gravity meter observations in places where heights found by spirit-levelling are few or absent.

There are two essays on geophysical subjects. Prof. Gutenberg's calculations of pressure as a function of depth beneath high mountains, beneath continental lowlands and beneath the deep oceans, in which he uses the most recent evidence about the properties of materials down to 50 km., emphasize again that, even assuming that the granitic layer is really composed of granite of density 2·67 gm./cm.^{3}, the mean density of 2·67 gm./cm.^{3} for the upper layers usually postulated in isostatic calculations is too low and that existing isostatic anomalies calculated on the assumption of 2·67 gm./cm.^{3} do not represent the true disequilibrium in the crust of the Earth. E. Niskanen reviews the application of Bijlaard's theory of plasticity to the buckling of the Earth's crust, but his calculations do little more than confirm what Sir Harold Jeffreys has so often emphasized—that buckling, in its usual engineering sense of elastic instability, never occurs in the Earth's crust.

In view of Prof. Heiskanen's own studies, the papers that will probably be read with most interest are those dealing with the determination of the form of the geoid—the gravitational equipotential surface at sea-level. Dr. de Graaff Hunter puts forward a new proposal for finding the difference between the deflexions of the vertical at two intervisible sites from comparisons of the apparent optical elevation of each above the other when the height of each above the geoid is known, the essence of his proposal being a new way of eliminating the effect of atmospheric refraction by symmetrical observations. In his present position, Prof. Heiskanen is responsible for a large programme, having the object of calculating the detailed form of the geoid from gravity measurements by using an integral formula due to Stokes. One of the difficulties of such a project is that there are no gravity observations in large areas of the Earth, and the question of the effect of these areas on the calculated form of the geoid is discussed in two papers: one, by Prof. Hirvonen, on a spurious first-order harmonic term that may be introduced; and the other, by Prof. Vening Meinesz, on the estimation of the magnitude of the effect from plausible assumptions about the isostatic anomalies in the unsurveyed regions. An aspect of the theory of the application of Stokes's formula to the actual Earth is considered by Dr. Ledersteger, who calculates the effect of topography on the gradient of gravity between the surface of the topography and the geoid.

Most of the papers in this volume deal with topics of current interest, and none is within its limits inadequate; yet the collection as a whole leaves one disappointed. When such a collection is prepared, the reader may hope that, taken together, the subjects of the essay will give him a good idea of the important work in progress in the particular field; but the present collection does not do this, not even for current work in Europe, to say nothing of that in Britain or America. There is, for example, no paper on the problem of establishing a consistent world-wide gravity network on which a great deal of work is being done, nor is there one from Prof. Heiskanen's own group in the United States dealing with any of the interesting work being done there.

Furthermore, anniversary volumes afford an opportunity for critical reviews or expositions of important new ideas, and again it must be said that, in this volume, the opportunity has been missed. This work does indeed do honour to a distinguished colleague, but the honour would have been greater had the anonymous editors conceived it on broader lines and encouraged their contributors to write with greater depth.

A. H. COOK

DETAILED REPORTS ON NUCLEAR ENERGY

Progress in Nuclear Energy

Series 1: Physics and Mathematics. Vol. 1. Edited by R. A. Charpie, J. Horowitz, D. J. Hughes and D. J. Littler. Pp. x+398. (London: Pergamon Press, Ltd., 1956.) 84*s*.

THE Geneva International Conference on the Peaceful Uses of Atomic Energy released a welcome flood of information, and the long process of assimilation is now under way. This first volume of a series on the physics and mathematics of nuclear energy is largely devoted to helping the process by a number of critical reviews of the data presented at the conference, although some additional material is also included. Subsequent volumes, we are told, will be published as progress demands. The same plan for the first and later volumes is to be followed in the seven related series on reactors, process chemistry, technology and engineering, metallurgy and fuels, biological sciences, medical sciences and economics.

The striking feature of the first volume is its detail; these are articles for the expert to relish, not for the student to face. In some respects, however, the detail is fascinating for anyone: the elegant graphs in the article by J. A. Harvey and J. E. Sanders show scores of points from laboratories in many countries all lying snugly on smooth curves and explain why V. F. Weisskopf was stimulated by the Geneva Conference to write his foreword to this volume on the theme that science is international.

The Harvey–Sanders article on a summary of data on the cross-sections and neutron yields of uranium-233 and -235 and plutonium-235 and the associated one by P. A. Egelstaff and D. J. Hughes on their resonance structure form a valuable source of information on these important nuclei. H. A. Bethe's theoretical analysis completes a trio of reports on the fissile materials and gives the main conclusions to be drawn from the experimental data.

The volume becomes more general with an excellent survey of experimental techniques for measuring neutron cross-sections, but returns to the particular when dealing with the cross-section of xenon-135, the fission product which is so important as a reactor poison. G. R. Keepin's article on delayed neutrons emphasizes the important part they play in the control of chain reactions and gives extensive information on their energies, periods and abundances. In this and a later article and also in other recent publications the 'dollar' is used as a unit of reactivity; this seems to be inviting confusion with economics.

The articles mentioned so far are connected with the background information for reactor design. The last four articles deal with various aspects of complete reactors: S. M. Feinberg gives a detailed discussion of the methods used in the U.S.S.R. for the calculation of heterogeneous reactors; Dixon Callihan writes on homogeneous assemblies; the experimental and theoretical work with highly enriched reactors is described by H. Hurwitz and R. Ehrlich for intermediate and thermal energies; and that for fast reactors by J. Codd, L. R. Shepherd and J. H. Tait. The section on fast reactors includes a very interesting description of the Harwell experimental reactor, ZEPHYR, and some of the results obtained with it. These articles cover very recent work and show the beneficial effect which the Geneva Conference had on the release of information. Perhaps it is a little too much to expect that the next volume in this series will have a detailed article on fusion.

J. WALKER

GENES, SPECIES AND MEN

Evolution, Genetics and Man

By Prof. Theodosius Dobzhansky. Pp. ix + 398. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 44*s*. net.

EACH phase of the development of evolutionary theory has been characterized by books and monographs dealing with various aspects of the field. Prof. T. Dobzhansky's main contribution has been a comprehensive study, first published in 1937 and now in its third edition, on "Genetics and the Origin of Species". His present book is intended to form a simple introduction to evolutionary studies, and to point out the "bearing of the topics discussed on human problems".

The introductory chapter deals with the continuity of life, and the author then enters into a discussion of the basic principles of genetics. This section occupies by far the greater part of the volume. It is developed along what have now become conventional lines to include accounts of the origins of genetic variability, the genetics of populations, the mechanics of natural selection, adaptation, and the formation of races and species. The principles elaborated in these first eight chapters are illustrated by instances of the rapid evolutionary changes that have taken place in domestic animals and plants.

Then follows a discussion of the 'principles' that have been developed empirically in the field of comparative anatomy. It is somewhat surprising that the author apparently makes little attempt to survey the theoretical background of this subject critically in the light of genetical findings. He does nevertheless point out that genes control biochemical processes during embryonic development rather than individual characters of the adult; but again, little mention is made of the new and relevant concepts that have been developed in the field of 'epigenetics'.

A chapter on the evolution of sex follows. This might have been more suitably placed in the earlier part of the book for, in its present position, it breaks the continuity between the discussion of the principles of comparative studies and the survey of the fossil record that follows.

The author deals rapidly with the main features of the evolution of the vertebrates, and as the text proceeds, less and less prominence is given to the genetic background. Finally, the reader is confronted with a not unduly critical account of the fossil remains of man's presumed ancestors. Prof. Dobzhansky stresses that living men form one species, and concludes with a discussion of the evolutionary possibilities that are open to man as being the only animal capable of conceptual thought and therefore able to transmit culture.

There can be little doubt that, for many students, Prof. Dobzhansky's book will provide a stimulating introduction to the genetic basis of the biological variation on which selection acts. The unevenness of his work may well reflect the fact that the very size of the subject precludes any one scholar from being equally competent in all its branches. A companion volume providing an introduction to the elements of developmental genetics, and to the application of genetical principles to the study of palæontology and comparative anatomy, would prove a welcome addition to present-day evolutionary literature.

E. H. Ashton

THE LOWER PRIMATES AND EVOLUTION

The Non-Human Primates and Human Evolution

In Memory of Earnest Albert Hooton, 1887–1954. Arranged by James A. Gavan. Pp. v+134 (8 plates). (Detroit: Wayne University Press, 1955.) 3.50 dollars.

In a symposium at the annual meeting of the American Association for the Advancement of Science in 1953, a series of papers was presented on the relation of studies of the lower Primates to problems of human evolution. These papers were published in the issue of *Human Biology* for September 1954, and have now been republished in the form of a book dedicated to the memory of the distinguished American anthropologist, Dr. Earnest A. Hooton, who died in 1954.

While the title was no doubt suitable as an indication to the contributors of the main theme of their symposium, it is not altogether appropriate for this volume, since it implies to the prospective reader that the subject is treated with some degree of comprehensiveness and in logical sequence. In fact, the book consists of a number of short articles dealing with rather disconnected subjects, not all of which have a very obvious relation to immediate problems of human evolution.

Three essays on the study of behaviour in lower Primates will be found of more particular interest, for the reason that they present some original ideas which, it is suggested, may have a bearing on the mental and cultural evolution of the early Hominidæ. Dr. C. R. Carpenter advances tentative generalizations on the grouping behaviour in non-human Primates—generalizations which (he makes clear) are no more than hypotheses to provide a basis for future studies. Dr. H. W. Nissen discusses problems of mental evolution in Primates, and insists that there are no fundamental or qualitative differences between the emotions and motivations of man and the other Primates: "What especially characterizes human motivation is not its initiating goals, but rather the indirection and complexity of its approach to those goals". Finally, in an article by Dr. and Mrs. K. J. Hayes, an attempt is made to relate personal observations on a young chimpanzee (who spent the first six years of her life in their home) to speculations on the sequence of events which led to the development of cultural behaviour in human evolution.

It is a pity that two of the most interesting papers presented at the actual symposium—interesting because they deal with subjects about which there is so little published information—are only recorded in this book in the form of short abstracts: Dr. G. L. Jepsen, on the fossil Primates of the New World, and Dr. G. E. Erikson, on the comparative anatomy of the New World Primates.

W. E. Le Gros Clark

PARASITES OF LIVESTOCK

Veterinary Parasitology

By Dr. Geoffrey Lapage. Pp. xvi+964+34 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1956.) 63*s*. net.

While the medical man is adequately supplied with text-books on human parasitology in the English language, the veterinarian is less fortunately situated; for there are scarcely any modern books covering the field of animal parasitology, in spite of the economic and public health importance of parasitic diseases in livestock. There is therefore an urgent need for an up-to-date handbook dealing with the parasites and the diseases produced by them in domestic animals. No one could be better qualified to undertake this formidable task than Dr. G. Lapage, who has now provided teachers of animal parasitology and veterinary students with a comprehensive account of the protozoa, helminths and arthropods of veterinary importance.

Two introductory chapters are devoted to the general principles and concepts of parasitism, such as the types of animal associations, the characteristics of parasites, their life-cycles and methods of transmission, their effects upon the hosts and the reactions of the latter to infection. The remaining twenty-eight chapters are divided into four parts dealing (in the order that follows) with nematodes, flat worms, arthropods and protozoa. The description of the species considered in each of these phyla includes their systematics, morphology, life-history, host–parasite relations, control and drug treatment, illustrated by numerous text figures and plates. Among the arthropods are included—in addition to true ecto- and endo-parasites—also vectors of parasitic infections, as well as species which affect the health and well-being of livestock in other ways. Although the parasites are considered mainly from the zoological point of view, the course and epidemiology of the infections are described in some detail; but data on their therapy are only briefly mentioned, while diagnostic procedures are left out altogether. However, since this book does not claim to be a practical guide to clinical parasitology, and its size had to be kept within the bounds of a single volume, omissions could scarcely be avoided. Readers desiring to extend their knowledge of parasitology will find the necessary references in the bibliography, which occupies twenty pages. There is also a useful alphabetical index.

This authoritative and comprehensive text-book, which successfully fills the gap in the literature on parasitology, will be welcomed not only by veterinarians—for whom it is primarily intended—but also by medical workers and zoologists.

C. A. Hoare

A Supplement to the Catalogue of the Grace K. Babson Collection of the Works of Sir Isaac Newton and Related Material in the Babson Institute Library, Babson Park, Massachusetts

Compiled by Henry P. Macomber. Pp. viii+91. (Babson Park, Mass.: Babson Institute, 1955.) 4.90 dollars.

IN 1950 appeared the "Catalogue of the Babson Collection of the Works of Sir Isaac Newton", an ordered description of an important Newton library, housed in Babson Park, Massachusetts (see *Nature*, 166, 284; 1950). The present "Supplement", compiled by Mr. Henry Macomber, the curator of the Collection and associate compiler of the original catalogue, lists a number of items of all kinds—books, reprints, manuscripts, photostats, photographs, portraits and so on—which have accrued to the Collection since the first catalogue was issued.

There are a few early books of high importance, such as copies of Huygens's "Horologium Oscillatorium", Kepler's "Astronomia Nova", l'Hospital's "Analyse des Infiniment Petits" and Hooke's "Micrographia"; but many of the acquisitions are in the way of recent writings about Newton, including reprints and extracts from journals. There are also a number of items of minor interest, in the case of some of which the Newtonian interest tends to be remote, as, for example, Hollar's etching of the Royal Exchange, made in 1644, which is a charming work, and an odd Vol. 1 of a two-volume edition of Boswell's "Life of Samuel Johnson", published in Philadelphia in 1841.

The work is produced uniformly with the original catalogue, all owners of which will certainly wish to acquire this supplement, which, incidentally, contains an errata list for the original volume.

E. N. da C. Andrade

Progress in Organic Chemistry

Edited by Prof. J. W. Cook. Vol. 3. (Progress Series.) Pp. viii+273. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1955.) 45*s*.

THE third volume of this useful series certainly continues to enhance its reputation for providing up-to-date reviews of live topics. The first survey, on the total synthesis of steroids, by Dr. J. W. Cornforth, is that rarity—a comprehensive account of a complex subject written with clarity, modesty and humour. Every synthetic route is discussed and the story of this triumph of organic chemistry makes stimulating and enjoyable reading.

Since Prof. W. Baker's 1945 Tilden Lecture on non-benzenoid aromatic compounds, important new advances have been made in this field, and it is fitting that Prof. Baker (with Dr. J. F. W. McOmie) contributes to the volume a chapter on these compounds, which fully incorporates the recent work. This account is complemented by the succeeding chapter on the fulvenes, by Prof. E. D. Bergmann, which is a very full description of these interesting compounds.

The advantages of organo-lithium compounds over the more conventional Grignard reagents have been gaining recognition for some time. The chapter on organic compounds of lithium, by Prof. E. A. Braude, is therefore particularly timely and useful, and achieves a nice blend of practical and theoretical considerations. The pharmacological properties of reserpine have focused much recent attention on the yohimbine group of alkaloids. In the final chapter, on the indole alkaloids, Profs. V. Boekelheide and V. Prelog describe the modern investigations on this group and on other indole alkaloids, the unusual fine structures of which have been recently unravelled (the corynantheine, cinchonamine and erythrina alkaloids).

R. A. Raphael

An Index of Mineral Species and Varieties Arranged Chemically

With an Alphabetical Index of accepted Mineral Names and Synonyms. By Dr. Max H. Hey. Second, revised edition. Pp. xxiv+728. (London: British Museum (Natural History), 1955.) 60*s*.

IT is five years since the British Museum (Natural History) issued the "Index of Mineral Species and Varieties", compiled by Dr. M. H. Hey (see *Nature*, 167, 873; 1951). In the interval, much progress has been made in mineral chemistry, and the new edition of this valuable work of reference has been revised throughout by Dr. Hey. New information, up to March 1955, has been incorporated in the text, and last-minute addenda and corrections, up to April 1955, have been printed on four pages at the end of the book. The only other change is the addition of a "Pronouncing Index of Accepted Mineral Names", which has been included in an attempt to establish uniformity of pronunciation of mineral names in English-speaking countries—not an easy task; this index occupies sixty-six pages. Scientific libraries not already owning a copy of this work will no doubt welcome the opportunity to purchase it in its revised form.

Genetics in the Atomic Age

By Dr. Charlotte Auerbach. Pp. vii+106. (Edinburgh and London: Oliver and Boyd, Ltd., 1956.) 8*s*. 6*d*. net.

A GROWING number of persons are becoming concerned about the genetic consequences of the exposure of human populations to radiation, but few are well informed about the scientific principles underlying the question. This little book has the timely purpose of helping to fill this gap for the non-biologist, and is admirably designed to do so. It is a model of lucidity and conciseness. Dr. Charlotte Auerbach, herself a first-rank teacher and investigator in genetics, presents the facts necessary for a grasp of the radiation question without recourse to ratios, equations or technical terms. Mutations, their effects, their hereditary transmission, and their evolutionary role are discussed in four chapters; the final two deal with the production of mutations by radiation and with facts relevant particularly to the human problem, and examine the nature of the consequences that future generations of mankind may suffer through exposure of the present ones to radiation.

The drawings by Miss I. G. Auerbach are most helpful, and have an original charm of their own. An appendix of scientific terms, not themselves used in the text but describing facts and ideas explained there, will assist readers who go on to more technical writings in genetics.

This book will do much to give its readers the knowledge necessary to judge wisely the genetic hazard due to radiation. Its obvious power to stimulate interest would make it a valuable addition to any biology class-room shelf or school library.

Alma Howard

HIGH-ENERGY NUCLEAR PHYSICS

MOSCOW CONFERENCE

A CONFERENCE on high-energy nuclear physics was organized by the Academy of Sciences of the U.S.S.R., and the main sessions were held in the Lebedev Institute in Moscow during May 14–22. Although it was not officially described as an international conference, and physicists from the Soviet Union made up the majority of the six or seven hundred who attended, visitors from many other countries were also present as the guests of the Academy of Sciences. They included thirteen from the United States, seven from the United Kingdom, and others from the European Organization for Nuclear Research, Canada, Australia, France, the Federal German Republic, Italy, Norway, Sweden, Yugoslavia, Egypt, India, the Eastern European countries and China. It was an exciting occasion. Many laboratories were open to visitors, and it was possible to discuss physics freely with Soviet scientists at their work, as well as in the conference hall.

The programme was a very full one, with many relatively short papers in three sections usually running in parallel. The numerous formal contributions, and the large audience, often prevented adequate informal discussion of the papers except in the theoretical section. However, in the later stages, the anterooms and corridors began to fill satisfactorily with physicists engaged in discussion; there were always plenty of interpreters to assist, and many of the Soviet physicists spoke excellent English. The language difficulty was partially overcome in the formal sessions by the use of simultaneous translation from Russian into English; English-speaking contributors had to wait at short intervals for the Russian translation to be interposed. One speaker made his address in Chinese, which was translated by one of his colleagues into Russian and thence, by the official interpreter, into English.

Accelerators

In the first session, opened by M. G. Mescheryakov, the most important Soviet high-energy accelerator projects were outlined by A. L. Minz, V. I. Veksler and V. V. Vladimirsky. The accelerators described were the 6-metre synchrocyclotron, which has been operating since 1949 at 480 MeV. and since 1953 at 680 MeV., the 10 GeV. proton synchrotron now nearing completion, a 6–7 GeV. alternating-gradient proton synchrotron, and a projected 50-GeV. alternating-gradient proton synchrotron. More detailed reports on these machines were given in the accelerator sessions proper; but in addition, papers were presented on practically every known method of acceleration of particles to high energy and on experimental techniques. Of the sixty papers read, all but seven were Russian. There has been a great upsurge of activity in high-energy accelerator development during the past few years, but the Soviet effort in this field, revealed in full for the first time, is on a very massive scale by any standard.

We visited the Institute for Nuclear Problems, situated about 120 km. north of Moscow near the junction of the Volga with the Moscow–Volga canal, to see the two large accelerators. The Institute also contains a high-flux reactor and a heavy-ion accelerator, and is being built into a major centre for all aspects of nuclear physics under the direction of Blokhintsev. It is understood that ultimately it is to be an international centre, with eleven Communist States invited to share the facilities free of charge; we were told that physicists from Western countries would also be able to work there.

Both accelerators impressed by the excellence of their engineering. Of particular interest was the radio-frequency system of the 6-m. synchrocyclotron; this appeared, to those of us with experience in the field, the most elegant we had seen. Moreover, the reported operating data put the system ahead of all others known to us in respect of reliability and performance. The experimental enclosures attached to the synchrocyclotron are well shielded and very large in area, and contained more apparatus, such as analysing magnets and equipment for particle detection, than we had seen in any other single installation. Here again the quality was excellent, but in some respects did not match the standard set by the machine itself; for example, the external proton beams had to travel considerable distances in air after emerging from a metal window in the vacuum chamber.

The larger machine, the 10-GeV. proton synchrotron, was nearly complete. Final assembly and adjustments were expected to be completed by the end of 1956. The magnet contains 35,000 tons of steel; but, contrary to some reports, is not at all extravagant in this respect for an energy of 10 GeV. in a constant-gradient machine.

The new alternating-gradient machine now being designed, for 50-GeV. protons, may not be built on the Volga site. It was described in a number of papers by V. V. Vladimirsky and his colleagues. Similar machines of 30 GeV. and 25 GeV. are in a rather more advanced stage at Brookhaven and the European Organization for Nuclear Research respectively, but the Russian group has made an original contribution whereby the transition energy phenomenon, requiring a change of the stable phase of the particles, may be avoided at the expense of a 20 per cent increase in orbit-path and weight of steel. This proposal may have limited practical value, however, because recent work at Brookhaven has shown that the transition point may be passed safely with the help of careful design and accurate control.

A symposium on high-energy proton linear accelerators was held at the Moscow Physical Institute (of which I. V. Kurchatov is director). A group in Prof. Artsimovitch's department there had become interested in the design study carried out at the Atomic Energy Research Establishment, Harwell, in which one of us (T. G. P.) was closely concerned, and had begun studies of their own. They stated their intention to construct a 1,000-MeV. machine of this type. An exciting programme in the same Institute is being conducted by a team under G. I. Budker. This involved the production, in an apparatus of betatron type, of an intense circulating beam of relativistic electrons, 'pinched' by neutralization of the space charge by the introduction of positive ions. Inside this electron beam there may exist intense magnetic fields with a spatial configuration such that stable orbits of high-energy protons may be set up. The protons may be accelerated by the application of radio-frequency fields. If successful, this project could lead to the construction of an accelerator for 100 GeV. with an orbit radius of 3 m.; but it is of fundamental interest in any event.

Experimental Results

The first section of the main session was devoted primarily to the presentation of experimental results, with some papers discussing their theoretical interpretation. Very many of the papers presented by the Soviet physicists described work that has been done with the 680-MeV. synchrocyclotron; with the nucleon and π-meson beams from this machine, they have been able to extend to higher energies knowledge of the cross-sections for the elementary scattering processes.

While for energies up to 300 MeV. most of the possible elementary experiments on scattering of nucleons have now been made, so that a phenomenological interpretation in terms of phase-shift is becoming clear, the more complex situation at energies up to 600 MeV., with the competition of the inelastic meson-producing events, is still far from being completely understood. Soviet physicists described preliminary work on the polarization of scattered nucleons at these energies, which will give some of the extra clues needed. Neutron–neutron scattering has been investigated with the help of deuterium targets, and the evidence supports the belief that the scattering should be the same as for protons on protons, as is already well known at lower energies. The scattering of π-mesons has now been explored up to 300 MeV., but the new data are insufficient to yield any fresh information about the interaction of mesons and nucleons.

Other sessions were devoted to photonuclear reactions, and to new particles. In the latter, A. I. Alikhanyan produced evidence for the existence of a new meson; in an analysis of the masses of cosmic-ray particles he found, in addition to groups corresponding to μ-, π- and K-mesons, a clearly separated group (twelve events) of particles with a mass of 560 ± 120 electron masses.

In addition to the papers by Soviet physicists, there were a number of papers presented by the visitors, especially those from the United States, surveying recent and current work on the same topics in other institutes.

Field Theory and Related Matters

There were four sessions devoted to field theory and other technical theoretical matters. These naturally did not command so large an audience as those in the main section, but the sustained interest of a large number of young Soviet physicists was remarkable. Several of the papers presented related to the question of the utility of field theory; a subject which also overflowed into the main section. One extreme point of view, strongly advocated by L. D. Landau, I. Ya. Pomeranchuk and others, contends that the theory is nonsense because a logically consistent discussion of the solution of the equations appears to lead to the absurd conclusion that there is no interaction at all between different fields. Against this it is contended, not only that this conclusion has not been proved rigorously, but also that, in meson physics, the field theoretical ideas have proved to be qualitatively correct in many respects, and should be retained as a guide until a better theory can be formulated.

Among the applications of field theory there was discussion about the formulation and use of 'dispersion relations' for the scattering of nucleons; at present there is no simple way of using these, analogous to their successful employment in the discussion of meson scattering.

The discussions at this conference, and the close personal contacts made at many levels, were very encouraging for future international collaboration in scientific work. There appears to be reason to hope that they will be followed, not only by further conferences in which East and West will co-operate, but also by individual visits and by correspondence on matters of common interest.

T. G. Pickavance
T. H. R. Skyrme

GENEVA CONFERENCE

The symposium on High Energy Accelerators and Pion Physics, organized by the European Organization for Nuclear Research (C.E.R.N.), was held in the Institute of Physics of the University of Geneva during June 11–23. Although some of the participants had attended the Moscow Conference, and a few of the papers were repeated, the great majority of the papers were heard for the first time. There were representatives of all the twelve member States of the Organization, about fifty each from the United States and the U.S.S.R., and others from Australia, Canada, Czechoslovakia, India, Spain and the United Nations Educational, Scientific and Cultural Organization.

High-Energy Accelerators

The first week was devoted to high-energy accelerator problems, with the emphasis on new ideas rather than recitations of lists of parameters. Authors of main papers, of 30 min. duration, had been invited to submit texts well in advance for reproduction and distribution by the Organization, and nearly all of them had co-operated. This procedure lends itself well to accelerators, development of which takes years of effort by large teams, though less well to experiments in physics. Many authors had taken the opportunity to write up their work in considerable detail and at greater length than could be accommodated in a half-hour talk. The conference 'preprints' were therefore very useful documents, and greatly aided discussion after the formal presentation of papers. Ample time was left for informal discussion, and there were no parallel sessions.

Main papers were presented by the Middle West (MURA) Group from the United States (D. W. Kerst, K. R. Symon, L. W. Jones) on the new fixed-field alternating gradient machines (FFAG). The object of the MURA project is to accelerate protons to energies of 15 GeV. or more, in a ring-shaped magnet energized by direct current and accommodating a large range of particle momenta in a small range of orbit radii. A disadvantage of normal synchrotrons, whether of constant gradient or alternating gradient type, is that the rate of repetition is limited to a low value by the problem of cycling the magnetic field; this difficulty is absent from machines of fixed-field type, and much higher intensities are hoped for. However, it is necessary to introduce azimuthal variations of magnetic field, and there are severe fundamental difficulties in establishing a stable system of particle dynamics. High-intensity operation also poses serious radio-frequency and phase-stability problems. All these matters were discussed, together with a proposal by the MURA group to combine the beams of two such accelerators so that protons travel in opposite directions before collision. The energy liberated in the centre of mass system of co-ordinates would then be 30 GeV., for two 15-GeV. accelerators, and this would correspond, in the usual system where the target proton is at rest, to a bombarding energy of about 600 GeV. However, very high beam intensities would be needed for a useful yield of collisions.

Colliding-beam systems have been discussed for many years, but efforts are now beginning to be made to discover means of making them more plausible. There was much discussion of 'storage rings', for example, by W. M. Brobeck (Berkeley) and G. K. O'Neill (Princeton). A pair of these could produce colliding beams in a common sector, the rings being fed alternately by a single high-energy accelerator. Some of the informal discussion entered the realms of fantasy, but it was very stimulating.

Fixed-field alternating gradient systems may also be applied to cyclotrons, and a main paper by the Harwell group (T. G. Pickavance) discussed studies of machines of that type for high-intensity operation at about 3 GeV.

Three important Russian papers were presented on 'new ideas'. A. Naumov reported the work of Budker on relativistic stabilized electron beams (previously reported in Moscow). V. I. Veksler, in a most interesting contribution, speculated upon the possibility of accelerating particles in dense bunches using the field between a bunch and another group of charges, a plasma, or an electromagnetic wave. Such methods Veksler called 'coherent', because the force on a single particle would be proportional to the number of particles in the bunch. One possibility would be to exploit an 'inverse Cerenkov effect', according to which a medium, travelling rapidly past a charged particle, imparts energy to the particle. Ya. B. Fainberg discussed a system in which a plasma could be made to act as a wave-guide, particles being accelerated by an applied radio-frequency field. Phase and radial stability could be achieved and power losses would be less than those experienced with ordinary metal waveguides.

The remaining accelerator sessions dealt mainly with problems of existing machines or machines under construction. Papers on phase transition, radio-frequency acceleration injection, and extraction were presented by members of the Brookhaven, CERN and Russian groups concerned with the large alternating-gradient proton synchrotrons, and on magnet problems by the same groups and by M. Bruck (Saclay), J. M. Blamey (Canberra) and D. W. Kerst (MURA). There was a session on the important topic of non-linear betatron oscillations, in which main papers were read by R. Hagedorn (CERN), E. D. Courant (Brookhaven), A. A. Kolomenski (U.S.S.R.) and K. R. Symon (MURA), and another on linear accelerators with contributions from Brookhaven, Harwell, Kharkhov, Berkeley and Stanford. L. W. Smith (Brookhaven) and E. J. Lofgren (Berkeley) reviewed the operational problems of the 3-GeV. cosmotron and the 6-GeV. bevatron, respectively. These two great machines have now become organized facilities for research; the scale of organization required impressed everyone at the conference. For example, the bevatron requires the full-time services of nearly eighty people, from graduate physicists and engineers to craftsmen and technical assistants, not counting the research workers engaged in experiments. A degree of organization, at one time considered foreign to fundamental research, has therefore to be applied to the research programme; this is a difficult problem.

The accelerator sessions were most lively and successful, and it was noteworthy that the informal discussion was maintained at an exceedingly high standard to the end. Accelerator studies have developed into a branch of learning in their own right, and the conference showed that many laboratories in many countries are making vital contributions to this rapidly advancing field.

Developments in Technique

The first one and a half days of the second week were devoted to discussions of developments in technique. An introductory talk by D. A. Glaser, of the University of Michigan, on bubble chambers was followed by seven other papers on the subject from laboratories in France, Italy, the United States and the U.S.S.R. Attempts to improve the cycling time of cloud chambers were discussed by British and American groups.

In a review of recent advances in millimicrosecond-counting techniques, O. Chamberlain (University o California) mentioned the production of an experimental transmission type of photomultiplier by Sternglass and Wacktel, of the Westinghouse Research Laboratories. In one design the multiplying electrodes consist of gold foil 20 A. thick followed by a layer of potassium chloride 450 A. thick. The tubes require a few kilovolts per stage, and with seven stages of multiplication yield pulse-rise times of less than 1 millimicrosecond, but at the present stage of development they suffer from severe fatiguing troubles. A new R.C.A. tube (type number 6810) is, however, commercially available and this has the advantage of an output of 0·3 amp., so that for many applications it is possible to dispense with further amplification. By limiting the area of the photocathode it is possible to get rise-times as short as 1·5 mμsec.

One afternoon of the conference was devoted to the presentation and discussion of experimental results. It is perhaps a significant pointer to the future that pride of place was given to a session entitled "Antiproton Physics". E. Segrè gave a review of the antiproton work at Berkeley. For the time being, antiprotons have been produced only by proton bombardment of copper targets in the bevatron. From a study of stars produced by the interaction of antinucleons with matter, it has been determined that some stars show a visible energy release greater than Mc^2, which is proof that the antiproton is annihilated with a nucleon. It is not yet known whether the mechanism of production is a nucleon–nucleon collision producing an antinucleon–nucleon pair, or whether an intermediate step involving the production of a π-meson is required.

Interaction cross-sections in beryllium and in copper have been measured and found to be about twice the cross-section for protons. A possible explanation of this unexpected result has been given by Duerr and Teller (*Phys. Rev.*, 101, 494; 1956).

Another striking event of the conference was an announcement by Prof. W. Pauli of news from the United States that the well-known inverse beta decay experiment of Cowan and Reynes had yielded a positive result, compatible with a cross-section of about 6 × 10^{-44} cm.^{2} Evidence for the existence of the neutrino has thus been established.

Meson Physics

Most of the remaining sessions were devoted to meson physics. This was a deliberate policy on the part of the organizers of the conference, who had in mind the experiments that will be carried out on the C.E.R.N. synchrocyclotron (due for completion in 1957). The continued great interest in this important field was illustrated by the large number of interesting papers presented from many laboratories. It must suffice to summarize the proceedings by saying that many experiments gave supporting evidence for the existence of an isobaric state of the pion–nucleon system and of such a state in the charged-pion production process.

An elegant experiment outside the field of meson physics was reported by R. Hofstadter, on the structure and size of the proton. This experiment was carried out by measuring the angular distribution and differential cross-section for the scattering of high-energy electrons by protons. At large angles and high energies, the cross-section for scattering deviates from that expected for a point proton by about a factor of nine. The results fix the root mean square radius of the proton at $0{\cdot}77 \pm 0{\cdot}10 \times 10^{-13}$ cm. for each of the charge and momentum distributions.

There were visits to the CERN site at Meyrin, near the French frontier. It was most encouraging to see the great progress made on the construction of the elaborate foundations and ring building of the 25-GeV. machine. Construction of the 600-MeV. synchrocyclotron appeared to be well advanced. The whole conference was well organized and was a good augury for the continued vitality of this absorbing field of study.

SYNTHETIC DETERGENTS AND THE TREATMENT OF WATER AND SEWAGE

SINCE 1949 there has been something like a threefold increase in the sales of synthetic detergent mixtures in Britain, the majority of which contain as their most important constituent anionic surface-active agents of the alkyl aryl sulphonate type. Although these substances are used to some extent in industry, the big expansion in their sale during the past ten years has been for domestic purposes. Thus most of the synthetic detergents now used in Britain are discharged by the housewife to the sewers of local authorities and, except in some coastal towns, eventually pass to a sewage-disposal works.

Domestic sewage is normally treated by sedimentation and biological purification, and although the methods used may appear to the uninitiated as somewhat crude and primitive, they are in fact extremely efficient and capable of effecting a high degree of purification at a remarkably small cost. They are, however, rather easily upset by the presence in the sewage of certain types of substances, particularly those which interfere with microbiological processes, this being the main reason why it is often difficult to treat sewage in an industrial district where large quantities of trade effluent are discharged to the sewers. During the past few years there has been a growing feeling that household synthetic detergents are among the substances which cause difficulties at sewage works. Moreover, it is known that part of the surface-active agent they contain often passes through a treatment plant and so is discharged with the effluent to a river. It is common knowledge that during the past few years there has been a marked increase in the extent to which foam is formed on polluted rivers, particularly at places where they pass over weirs, and this again is commonly attributed to the presence of the surface-active materials in the water. In some parts of Britain rivers to which sewage effluents have been discharged have to be used as a source of raw water for domestic supply, and there has therefore been some anxiety as to whether surface-active agents may persist throughout a water-treatment plant and so be present in the supply distributed to a town, particularly since this is known to have occurred during exceptionally dry weather in at least one place in the United States[1]. For these reasons the Minister of Housing and Local Government some time ago set up a committee under the chairmanship of Sir Harry Jephcott to study the subject; its report has just been published[2]. A few weeks ago also the Association of American Soap and Glycerine Producers (who make synthetic detergents), through a report prepared by F. J. Coughlin, chairman of the Association's Technical Advisory Sub-Committee on Research, has made available the results of its own observations on the position in the United States[3].

The report of the American Association gives the impression either that the effects of detergents are not so marked in the United States as they are in Great Britain, or that if they are the Association has not fully appreciated the difficulties that have been caused. It is certain that at many sewage works in Britain, and especially at those using the activated-sludge process, frothing has increased during the past few years to a point at which operation of the plant is made very difficult, and in some cases dangerous, and that this frothing is due to the presence of surface-active constituents of synthetic detergents in the sewage; indeed, the British report includes two photographs of frothing at sewage works, at one of which the layer of foam appears to be several feet thick. The American Association, while agreeing that frothing has increased in the United States, does not appear to accept that detergents are the cause of it. It says also that frothing on the surface of aeration tanks and activated-sludge plants can be stopped by increasing the concentration of activated sludge in the mixture aerated. This was not found to be so in Britain, where experiments were made, at the suggestion of Sir Harry Jephcott's Committee, at several sewage works without any marked success. An important point of principle is, in any event, involved here; the processes used at sewage works have been evolved from experience and experiments over many years and the conditions at any particular plant are chosen to bring about the most effective purification of the sewage. It is very rarely that they can be drastically changed merely to prevent some difficulty caused by the discharge to the sewers of some strongly interfering substances whether of domestic or industrial origin.

Where an effluent which would seriously interfere with sewage treatment is discharged to the sewers from a factory, it is very often required (legislation being available to enforce this) that it should be pre-treated by the manufacturer to remove the most noxious constituents. For example, effluents from electro-plating works are often treated in this way to remove cyanides and toxic metals. It is clear that washing waters containing synthetic detergents cannot be pre-treated by the housewife; but an obvious suggestion is that manufacturers of these substances should endeavour to produce materials which, though satisfactory for washing purposes, would be readily decomposed by the processes, including microbiological processes, commonly used at a sewage works. Difficulties in sewage treatment would thereby be greatly reduced, and the material would not be discharged with sewage effluent to rivers. Thus, any risk there may now be of constituents of detergents persisting in potable water supplies would be removed. Another important reason—not mentioned in the American report—is that it is known that surface-active agents in a river may seriously reduce the rate at which atmospheric oxygen dissolves in it[4]; it would be expected, therefore, that they would accentuate the de-oxygenation of a river containing a given amount of polluting matter.

One of the recommendations of the British report is that manufacturers of household synthetic detergents should investigate the possibility of producing efficient washing products based on materials which can be readily oxidized or eliminated when treated at a sewage works. The American industry also accepts that research of this kind is necessary and is sponsoring work at the Massachusetts Institute of Technology. Preliminary work in Britain[5] has shown that the resistance of alkyl benzene sulphonates to bacterial attack is correlated with the nature of the alkyl group, straight-chain compounds being much more readily decomposed than those with branched chains. The development of readily decomposable substances with the necessary detergent properties, and which could be economically manufactured from available raw materials, might obviously require lengthy research, but should surely yield to the combined attack of the organic chemist and microbiologist.

The question arises whether the public interest is sufficiently safeguarded while research of this kind is being carried out. It is reported that in 1955 a Bill was introduced in the Kansas Legislature which would have made it unlawful to put detergents into a public sewer. The British Committee has not recommended anything like such drastic action. The majority, however (four members dissenting), considered that there is at least a possibility that a serious situation might arise before a practicable remedy has been found. It points out that there are at present no statutory powers for controlling the composition of detergents sold to the public and recommends that the Government should consider whether to seek these powers now or to defer obtaining them until a clear need for them has arisen. It recommends also that in the meantime an advisory body, including representatives of the sewage authorities and manufacturers concerned and of appropriate Government departments, should be set up to give counsel and facilitate research, and to keep watch on the position at sewage works, on rivers, and at water works, in relation to the continued use of synthetic detergents of the type at present being manufactured.

THE STUDY OF MAN-MADE FIBRES

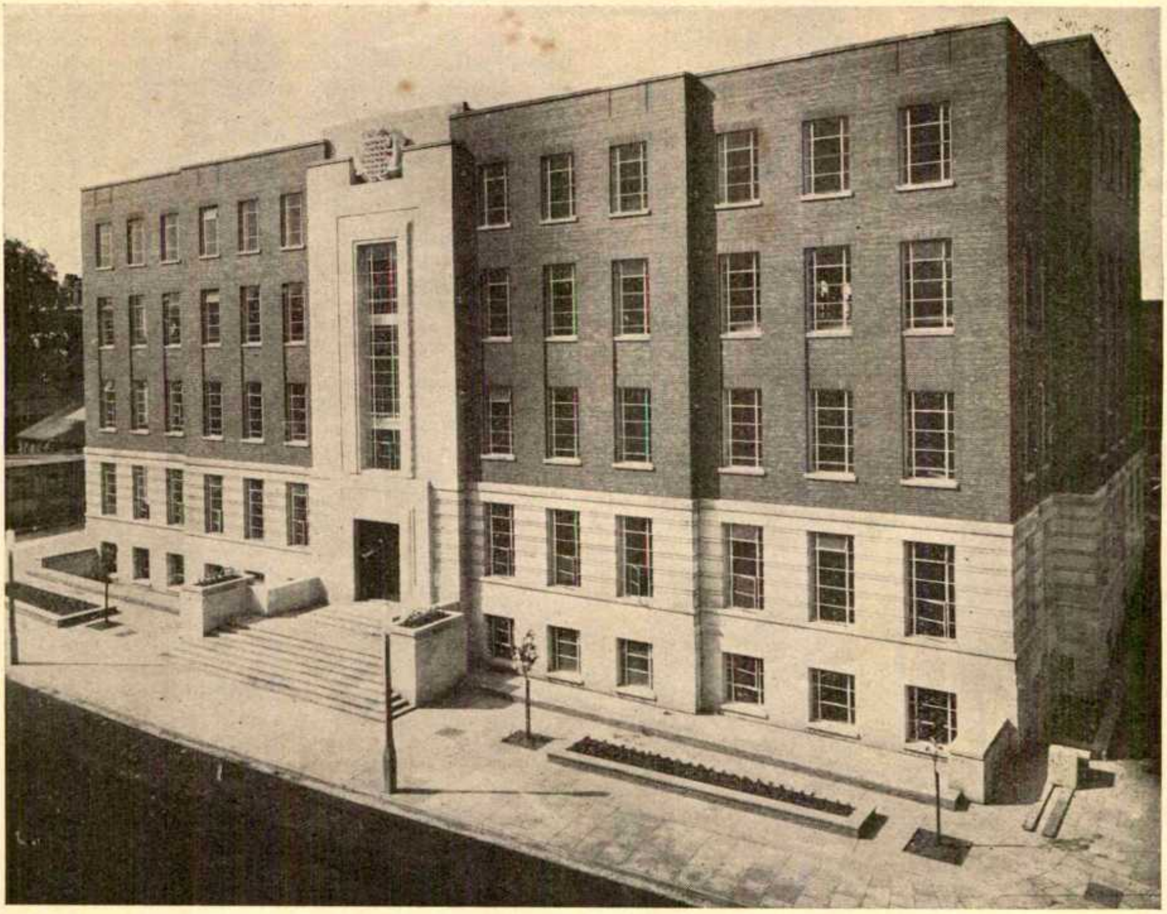
By Prof. J. B. SPEAKMAN

Department of Textile Industries, University of Leeds

A NEW building for the Man-made Fibres Division of the Department of Textile Industries of the University of Leeds was opened by the Duke of Edinburgh, in the presence of the Chancellor of the University, the Princess Royal, on June 29. Besides being the crowning point of some fourteen years endeavour in the Department of Textile Industries, the opening ceremony marks the beginning of a striking new period of expansion of the Faculty of Technology in a University which was already remarkable for its strength in the field of applied science.

The new Man-made Fibres Division is the direct outcome of the scientific revolution which the textile industry has undergone during the past forty years. Not only has this period seen the emergence of a science of fibres, based on the discovery of the main features of the constitution and structure of the chief natural fibres, with simultaneous rapid advances in the production of regenerated fibres from cellulose, cellulose acetate and proteins, but also the study of polymerization reactions has led to the synthesis of fibre-forming polymers and the manufacture of truly synthetic fibres.

Changes as profound as these could not, of course, take place without affecting the nature and scope of the training of the textile technologist; but progress seems to have been handicapped by the traditional structure of the textile industry in the United Kingdom. Regional segregation of industries based on the different natural fibres led to corresponding specialization in the main educational centres. Just as the University of Leeds focused attention on wool, so other institutions gave chief place to cotton, silk, flax or jute. Although the growing importance of man-made fibres has everywhere been recognized, pride of place is normally given to the natural fibres with which the institutions are traditionally associated,



Photograph by W. Blackledge, University Photographer

Fig. 1. Man-made Fibres Division, Department of Textile Industries, University of Leeds

and the man-made fibres are relegated to a second place bearing little relation to their importance in the national economy.

The magnitude of the man-made fibre industries may be gauged from the fact that, in 1954, the world production of regenerated fibres was about one-quarter of the world production of cotton and nearly double that of wool, while the production of fibres from synthetic polymers, which was negligible in 1935, was six times that of silk. Considerations such as these make it obvious that there must be at least one institution in the United Kingdom where the study of man-made fibres is not subordinated to that of natural fibres—one where textile technologists can receive specialized training for the industries which are engaged in making and using man-made fibres.

A project of this kind was conceived in 1942, and conversations were then begun with the directors of Courtaulds, Ltd., about the possibility of establishing a Man-made Fibres Division of the Department of Textile Industries in a new building near the Clothworkers' Departments of the University of Leeds, now the Wool Division. Immediate action was impossible because of the War, but with characteristic generosity Messrs. Courtaulds made a donation of £60,000 towards the cost of the building in 1947. This donation was followed by one of £40,000 from the Man-made Fibres Producers' Committee in 1949. By then, plans for the new building (Fig. 1) had been prepared by Dr. T. A. Lodge, the University architect; but the estimated cost was far higher than the sum available, building permits were difficult to obtain, and the shortage of labour was acute. In 1952, however, a grant of £201,000 was made by the University Grants Committee to cover the balance of the estimated cost, and work was begun in July 1953.

The Department of Textile Industries at Leeds has been fortunate also in receiving further generous donations towards the cost of equipping the new Division. These include £25,000 from the Man-made Fibres Producers' Committee, £20,000 from Imperial Chemical Industries, Ltd., £7,000 from the Federation of Calico Printers, and £5,000 from the Tootal Broadhurst Lee Co., Ltd., as well as £70,000 from the University Grants Committee. In addition, machines and other equipment have in many cases been supplied free or at reduced cost by the makers.

As may be seen from the photograph, the new building has four floors and a semi-basement. As regards machinery, the key floor is the first. Here, along the north wall, is housed pilot plant for demonstrating methods of producing viscose and cellulose acetate rayons, nylon, 'Terylene' and orlon. Cotton carding and spinning machinery for converting staple fibre into yarn is housed in an adjoining room in the centre of the building, and continuous filament and staple fibre yarns are converted into woven and knitted fabrics in rooms on the west and east walls, respectively. The carding and spinning, weaving, and knitting rooms are all provided with equipment for maintaining atmospheres of constant relative humidity. From the first floor the fabrics pass to the ground floor for dyeing (east end), printing (west end) and finishing (north wall). The ground floor includes also a dark room for the preparation of screens for screen printing, and two humidity rooms in which textile testing equipment is housed, one room being for use by undergraduates and the other for research students. On the second floor are two large laboratories for practical work in textile chemistry and textile physics by second- and third-year undergraduates, and the third floor includes a well-lighted design studio, for use mainly by students specializing in textile design, and two lecture theatres. Research laboratories are provided on the south side of each floor: in the semi-basement, for textile physics (electron microscopy, infra-red spectroscopy and X-ray analysis of fibre structure); on the ground floor, for applied chemistry (dyeing and finishing); on the first floor, for textile engineering; on the second floor, for textile chemistry; and on the third floor, for applied physics and textile chemistry (chemistry of high polymers).

In accordance with the 1942 plan, therefore, the Man-made Fibres Division is self-contained. It possesses equipment covering all stages of processing from fibre to fabric and confirms the rising stature of the man-made fibre industries. The advantages attached to the creation of the new Division have not, however, obscured its dangers. There is a unity in the science of fibres which transcends divisions, and there is so much common ground and interplay between the various branches of textile technology that division is dangerous. For these reasons, the Wool Division and the Man-made Fibres Division are to be regarded as complementary. Together they provide unrivalled opportunities for teaching and research, and all members of the staff will have responsibilities in both Divisions. Similarly, undergraduates will make use of both Divisions in the early years of their courses, leaving specialization in either wool or man-made fibres to the final year. In this way the unity of the science of fibres will be preserved and the growing unity of textile technology promoted.

In his address at the opening ceremony, the Duke of Edinburgh stated that "This new building can only be justified if the Man-made Fibres Division has constantly in mind that its work can be of direct service to the country. . . . The Division cannot possibly flourish without the active and continued interest of the industry, and I would go further and say that the Division will only be kept up to the mark if the industry makes sudden and impossible demands upon it". The close and cordial relationships between the Department of Textile Industries and the industries it serves ensure that such demands will be made and the high hopes entertained of the new Division realized.

GRASSLAND RESEARCH INSTITUTE: NEW RESEARCH BUILDINGS

By Dr. WILLIAM DAVIES

Director

THE new research laboratories of the Grassland Research Institute at Hurley, Berkshire, were opened by the Right Hon. D. Heathcoat-Amory, Minister of Agriculture, Fisheries and Food, on June 29.

The Institute was founded in 1949 for the investigation of grassland and of the many problems associated with the production and use of pastures by the grazing animal. The governing body is under the chairmanship of Sir James Scott Watson and consists of scientists and practising farmers, who are appointed by the Ministry of Agriculture, Fisheries and Food, the Secretary of State for Scotland and the Agricultural Research Council, the latter being responsible for the scientific supervision of the Institute, which takes its place among the other grant-aided research stations operating under the scientific guidance of the Agricultural Research Council. The Grassland Research Institute was preceded by the Grassland Improvement Station, established in 1940 at Drayton (near Stratford-on-Avon) under the inspiring leadership of Sir George Stapledon. In 1949 the new Institute took over the functions, facilities and staff of its forerunner, but since that time has considerably extended in terms of both staff and facilities. The new research buildings at Hurley have been in full occupation since the autumn of 1955 when, for the first time, the scientific staff had the very real advantage of working together at a single centre with adequate laboratory and field facilities.

The opening of the new laboratories marks, therefore, the end of the first important phase in the development of the Institute. The scientific staff can now settle down to develop the research programme, the basis of which is already laid. As this programme unfolds and is developed along lines of fundamental research both in field and laboratory, it will provide new information leading to improved techniques upon which progress in grassland farming can be made.

The main work of the Institute is concerned with the study of herbage as a crop for feeding to farm animals, and also as a medium for maintaining and improving the crop potential of the soil. Untended grassland is characteristically seasonal in growth, showing a large peak of production in late spring and early summer, followed by a shortage after midsummer and little or no production after September. This marked seasonality in growth is accompanied by equally sharp differences in the quality of the herbage offering to the grazing animal, and this confronts the pastoral farmer with a difficult series of problems in stock husbandry. This is a matter of importance, because grassland in one form or another provides the main basis for the livestock industry as concerns cattle and sheep.

One important field of endeavour, therefore, is to investigate means for providing a more even supply of pasturage not only throughout the normal growing period from April to September but also into the autumn, winter and early spring. Because different

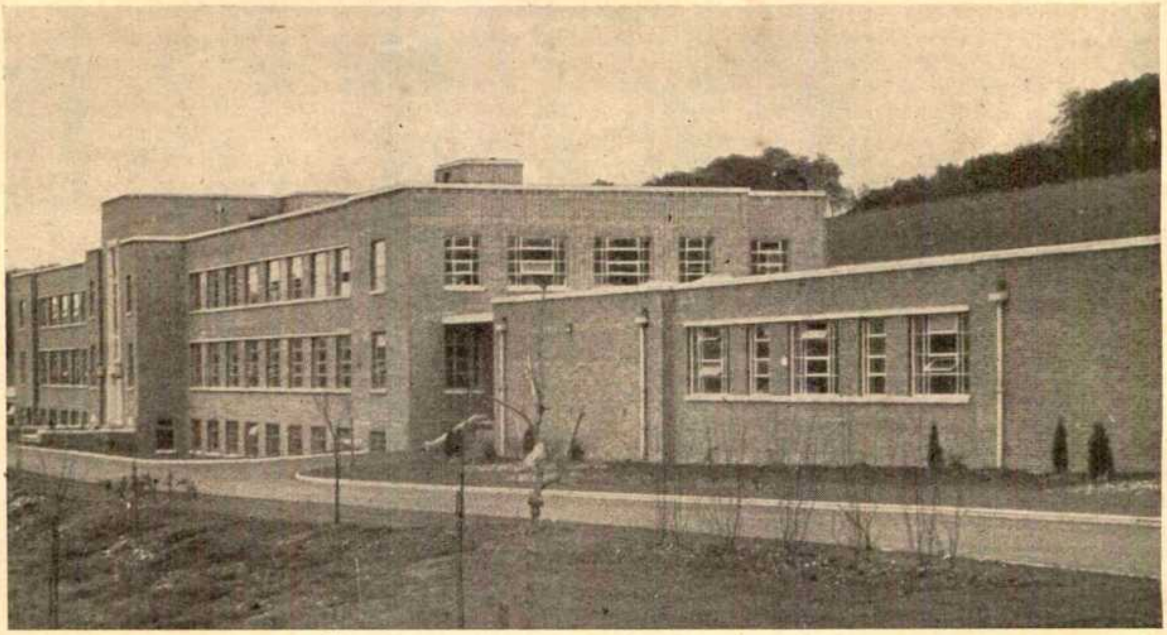


Fig. 1. New buildings of the Grassland Research Institute

species and strains of herbage plants show different growth rhythms, some emphasis is placed on using different seeds mixtures in order to provide for the periods of normally low production. Similarly, the influence of differential fertilizer treatments and of manner of usage of the pasture is being studied with the practical aim of extending the grazing season and of providing a more uniform diet for the grazing animal while at pasture.

The studies of the production and use of the grass crop, however, extend beyond the question of seasonality. The facilities offered by the new laboratories will enable the research staff to follow up the work already commenced in the sphere of animal nutrition and in the evaluation of herbages as livestock feed. Interesting studies on the appetite of animals at pasture are being made and some progress is apparent in the use of methods which will provide a more accurate picture of herbage digestibility as well as of herbage intake. No wholly satisfactory method is yet available which gives a true picture of what the animal eats when at pasture. Indoor feeding and digestibility trials provide only a partial answer and it will, therefore, be an important advance when a reasonably simple series of chemical values can be correlated directly with digestibility and other biological characters of the feed intake. Work along these and associated lines is in progress, and some of this is concerned with the biochemical study of herbage fractions, including both the proteins and the carbohydrates in herbage of different sorts and in various stages of growth.

Detailed studies are being made on growth and development in a number of the grasses, and this work is extended to studies into the physiology of seed production. The ontogeny of the grass shoot (that is, tiller) has been given attention and has led to the interesting suggestion that most tillers are annual or nearly annual. There is a large and very profitable field of work awaiting the attention of the physiologist in the study of both tops and roots of herbage plants subjected to different agricultural treatments. The facilities made available by the new research buildings enable the Institute to investigate a number of problems in this important sphere.

Capital grants for the construction of the laboratories and glasshouses at Hurley have been provided by the Ministry of Agriculture, Fisheries and Food. The main building is in brick with a flat roof. It is pleasing in appearance, due regard having been given to its site in the beautiful countryside of the Thames Valley and Chiltern Hills. The building is of two stories with semi-basement. The latter contains the instrument mechanics' workshop, various stores and several laboratories. It also includes a staff canteen of modern design, and a small staff common room.

The boiler house is at the eastern extremity of the basement. Heating is by oil-burning boilers which, in necessity, could be modified to use solid fuels. The whole building is panel-heated, the panel installation being in floor and ceiling. There are no radiators and therefore no obstructions to laboratory benching on this score. All laboratory equipment is electrical, and since there is no gas supply, all chemical work is also by electric heating, including nitrogen and other determinations. Butane gas cylinders are available for glass-blowing and for other occasional requirements. Demineralized water is serviced to certain of the laboratories, and this has already proved to be most useful. Plastic piping has been used extensively throughout the laboratories, including plastic waste and drainage pipes.

The ground floor houses plant physiology, part of the agronomy units, microbiology, entomology and biometrics. On this floor there are five large laboratories; two of these are for plant physiology, one is for herbage work, another for soil studies and the fifth for microbiology. In addition, there are a number of smaller laboratories and laboratory offices. The main conference room occupies a central position, and above it on the top floor is the Sir George Stapledon Library, which houses the joint Grassland Research Institute/Commonwealth Bureau of Pastures and Field Crops collection of books and periodicals.

The west wing (top floor) is occupied by animal agronomy, animal nutrition and biochemistry. The east wing contains the offices and administrative units of both the Institute and the Commonwealth Bureau of Pastures and Field Crops (Director, A. G. Glendon Hill).

Annexed to the main research block there is a one-story building which is essentially functional in design. This outbuilding contains the cold store (capable of holding 25–30 tons of deep-frozen herbage) with the refrigeration machinery. There is a large herbage weighing room, adjacent to which are grinder and oven rooms; the latter is equipped to house six 'Unitherm' drying ovens used for dry-matter determination on herbage samples. Near the cold store is a spacious metabolism house sufficient to hold twenty-four sheep crates at one time. Alternatively, it will house a dozen or so cattle in individual pens. Already a series of critical digestibility trials has been conducted in the metabolism house, feeding both fresh and frozen plant material to sheep. The outbuilding also contains space for storage, including a store for volatile chemicals, various workshops and arrangements to house technical equipment currently used in the field experiments. There is also shedding for tractors and other vehicles employed in technical work.

To the south of the main building space is reserved for the glasshouse block, and the first glasshouse (subdivided into six units) is already erected. This is heated and is thermostatically controlled. It has been designed primarily for physiological and related agronomic investigation.

The new laboratories at Hurley are well equipped and offer excellent facilities for conducting basic studies on biological materials. There is good laboratory accommodation of functional but simple design and excellent facilities for postgraduate workers, whether of Britain or overseas, to pursue investigations and to train in the important fields of grassland agronomy, animal nutrition, biochemistry of herbage materials, physiology of grassland plants, microbiology, soil problems relating to grassland, and biometrics as applied to grass and animal experiments.

At the opening ceremony, Mr. Heathcoat-Amory spoke of the vital part that the Institute would play in the future of British farming. "Making the most of grass" is the most important single way in which farmers can help themselves and their country. Nearly two-thirds of Britain's 31 million acres of farmland are under grass—but this great asset is under-exploited. Less than one-fifth of our grassland receives regular dressings. Mr. Heathcoat-Amory pointed out that this neglect of grass contrasts sharply with the care devoted to arable crops. The full exploitation of the grass crop would save millions of pounds in the national import bill; for the thousands of small farms, most of which will remain under grass, it offers the greatest hope for the future. The Minister summed up the present position by saying that grass is still taken for granted rather than treated as a crop. Advisory officers are, Mr. Heathcoat-Amory said, devoting more and more attention to the improvement, production and use of grass, and for guidance and news of progress they look to scientific research of the kind the Institute is doing so well. By all reports, the Institute is fulfilling its crucial role. The Minister was particularly impressed by the work being done to extend the grazing season—work of the greatest practical importance. The new laboratories mark, he said, another stage in the Ministry's programme of agricultural research, and proof of the value of this research can be seen in the increasing use made of new techniques and materials in agriculture. British agriculture can only hold its own in a competitive world by the extension and intensification of research —but the funds available for the purpose cannot be increased. Research is useless unless the results are passed on to other research workers and farmers. In this connexion he welcomed the fact that the Commonwealth Bureau of Pastures and Field Crops is housed in the same building as the laboratories.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, LONDON

REVISED EXPANSION SCHEME

THE architectural plans for new Imperial College buildings on the rectangular site bounded by Queen's Gate, Imperial Institute Road, Exhibition Road and Prince Consort Road were described and illustrated in *Nature* of April 21. The plans, prepared by Messrs. Norman and Dawbarn, provided for the very large new buildings needed for the major expansion being undertaken by the College at the Government's request. Much public attention was focused on one feature of the architectural scheme, namely, the proposed demolition of the Imperial Institute building, designed by Collcutt, the high central tower of which is a well-known feature of the London skyline. The Royal Fine Art Commission expressed the wish that the whole of the Collcutt building should be preserved. The London County Council, as town planning authority, considered the scheme would somewhat overbuild the site, and that a reduction in density might also make it possible to retain at least the tower of the Collcutt building. In consultation with the Royal Fine Art Commission and the London County Council, the College and its architects have now reconsidered the scheme, and have prepared the revised plans announced by the Lord Privy Seal in the House of Commons on June 21.

In the new scheme the Collcutt tower is retained as a free-standing campanile rising from a central court. The whole of the central area of the site has been replanned, and the height of the buildings reduced to avoid conflict between modern rectangular building masses and the tower. Asymmetrically arranged, the central area includes a building for Civil Engineering and one for Electrical Engineering. Behind them will be a Great Hall for about eight hundred, and a low central block containing refectories and common rooms. A high central block placed behind the Electrical Engineering building will contain libraries, administrative offices, common rooms and committee rooms (Fig. 1). The remainder

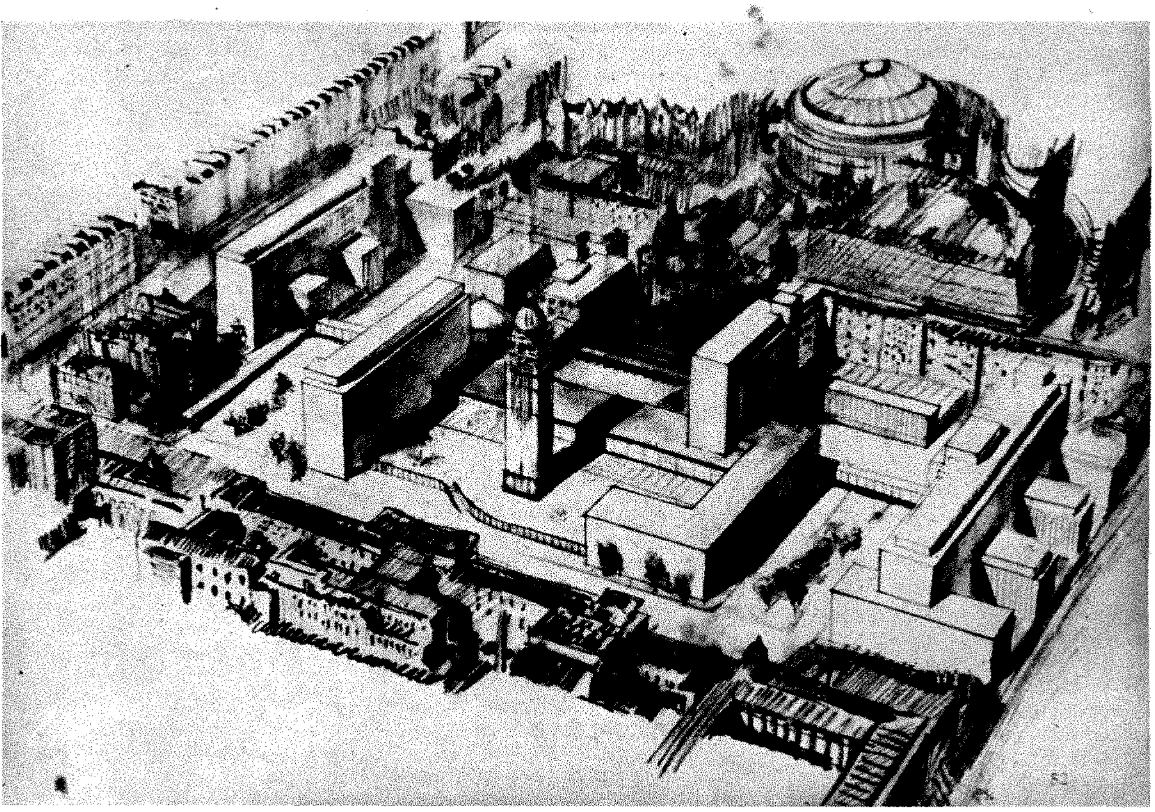

Fig. . Revised scheme, retaining the Collcutt Tower, for the Imperial College of Science and Technology

of the scheme for the main College expansion will be in accordance with the original plans. It has not been found possible to reconcile an expansion on the scale required with the retention of the whole of the Imperial Institute building.

The reduced density of building now proposed for the main site has been made possible by the recent acquisition by the College of the north, east and south sides of Princes Gardens. The Gardens lie just off Exhibition Road, and are about a hundred yards from the College buildings. These sites are reserved for residential purposes, and have been acquired by the College primarily to provide much-needed Halls of Residence for its students. The existing Halls cannot accommodate more than a very small fraction of the growing number of students, and the College hopes to provide 480 new study-bedrooms by the immediate development of the east and south sides of Princes Gardens.

While the Princes Gardens sites are not in any sense a substitute for the central site, the original plans for the central site provided for certain common rooms and refectory facilities which the Planning Authority is prepared to accept in Princes Gardens. Thus a portion of these facilities will now be transferred to the Princes Gardens scheme, where they will occupy half the new building proposed on the south side. The other half of the south side, and the new building proposed for the east side of the Gardens, will be for residence.

NEWS and VIEWS

Oceanography at Gothenburg :

Prof. Hans Pettersson, For.Mem.R.S.

PROF. HANS PETTERSSON, whose election to the foreign membership of the Royal Society of London was announced recently (*Nature*, 177, 918; 1956), retired on July 1 from the directorship of the Gothenburg Institute of Oceanography. Pettersson's activities have ranged over a wide field, with particular success in studies of the penetration of light into the sea and of the radium content of abyssal oceanic sediments. A burning desire to probe much deeper into the latter in the interests of geochronology than had earlier been possible led Pettersson during what he called "the enforced inactivity of the Second World War" to promote the construction of, and to test, the implements required. A novel vacuum corer developed in 1942 in association with Kullenberg gave place to the latter's very efficient piston corer, and thereafter the call was for opportunity to use it widely over the great ocean depths. It is Pettersson's crowning achievement that his boundless enthusiasm and persuasiveness produced the large funds which made possible the justly famed Swedish circumnavigation cruise of the *Albatross* during 1947–48, when, as leader, he so effectively fulfilled his "longing to grapple with the mysteries of the ocean floor".

Prof. E. B. Kullenberg

PROF. EINAR BÖRJE KULLENBERG, who succeeds Prof. Pettersson, was born in Scania, south Sweden, in May 1906, the son of a farmer. Educated at the

University of Lund, where he studied mathematics, physics and chemistry, Kullenberg graduated in 1928. Ten years later he gained his doctorate with a thesis, "Stark Effect of Hydrogenic Fine-Structure". Demonstrator in physics at the University of Lund during 1933–37; on the staff of the Swedish Hydrographic-Biological Commission for a number of years; a staff member of Gothenburg Oceanographical Institute since 1939; a lecturer in oceanography at the University of Gothenburg since 1942; associate professor there since 1948, and a member of the Swedish Board of Fisheries since 1949, Kullenberg has been his country's delegate to the International Council for the Exploration of the Sea since that year. Since 1947 he has been a member of the Academy of Arts and Sciences of Gothenburg, and was, in 1954, elected to the Royal Swedish Academy of Sciences. In 1947 he won the 10,000 Kr. Sixten Heyman Prize, and three years later the Walberg Gold Medal. Kullenberg is the author of publications on the Stark effect, on inertia currents in the sea, on internal waves, the water exchange in estuaries and channels, marine sediments, and the techniques of core sampling in the ocean depths. Widely and rightly famed for his important invention of the piston-corer which has made it possible to take long undistorted sediment cores from great depths, it was upon Kullenberg's calculations of the shapes of long trawl cables that the crowning success of the Danish *Galathea* Expedition in bringing up life from 10,190 m. depended.

Earthquake in the Aegean Sea

A STRONG earthquake with its epicentre near lat. 36° 24′ N., long. 25° 26′ E. occurred on July 9. The epicentre is in the Aegean Sea near the Island of Thira, or Santorin, which has some 15,600 inhabitants. It is reported that more than forty people were killed and several injured as a result of the earthquake, which caused considerable damage, particularly on the western side of the Island. A *tsunami* accompanying the earthquake, and initiated by ground movement on the sea-bed, is reported to have attained a vertical height of 12 ft. and to have travelled as far as Kalymnos, Astipalaia, Andiparus and Iraklion (Crete). The shock was felt in Athens, and was recorded at the Royal Observatory, Edinburgh, at 03h. 17m. 31s. G.M.T. Aftershocks continued for some days after the first earthquake.

The Solar Event of February 23

THE solar outburst that occurred on February 23, 1956, beginning at about 3.32 U.T., was certainly a very remarkable event. A large flare was observed in India (Kodaikanal) and Japan (Mitaka), and the Japanese observers report that the flare was seen in white light as a bright spot near the limb—a very rare observation. World-wide cosmic-ray effects set in within fifteen minutes, and the increase of the intensity of low-energy cosmic rays was greater than any previously reported. The nucleonic flux at sea-level in Britain appears to have increased by a factor of more than 40. Synchronous with the arrival of the cosmic-ray flux, there occurred a disturbance of the lower ionosphere on the night-side of the Earth of a type that does not seem to have been observed before. The reflexion ceiling for very low-frequency waves was lowered and the attenuation increased in a few minutes to beyond the normal day-time values. This effect must be attributed to particles penetrating down at least to the *D*-level, and it is thus to be thought of as connected with the cosmic-ray increase. The data concerning this event that have been obtained in the United Kingdom are published in the May issue of the *Journal of Atmospheric and Terrestrial Physics*.

Reduction of Expenditure in the Department of Scientific and Industrial Research

IN a written answer on July 5 to a question in the House of Commons the Parliamentary Secretary to the Ministry of Works, as representing the Lord President of the Council, said that the reduction of £150,000 in the published estimate for the Department of Scientific and Industrial Research was made up of £33,000 through slowing up the rate of recruitment of staff; £20,000 through reduced grants for industrial research; a reduction of £49,000 in capital and general expenses of departmental establishments, chiefly through economies in purchases of equipment and consumable stores; and a reduction of £20,000 by delaying the commencement of a new bore-hole for the Geological Survey. Increases in test fees and other similar charges would yield a further £70,000; but against these economies, expenditure on scientific grants was increased by £42,000, of which £37,000 was for nuclear physics.

Mathematics in Industry

IN the *American Mathematical Monthly* of February, Thornton C. Fry, of the Bell Telephone Company, writes on "Mathematics as a Profession Today in Industry". To-day we educate to-morrow's mathematicians, and our curriculum should be adapted to to-morrow's needs; we cannot forecast these needs in detail, but by extrapolation from what has happened during the past fifty years, we may be able to foresee general lines of development. We shall make new things, standards of precision will be more stringent, and over-all planning for a total situation will be at least as important as concentration on accuracy in functional components. Such tasks demand collective knowledge and the exploitation of collective knowledge demands collective action. The requisite breadth and depth of technical competence can be supplied only by a team of experts, fully equipped and co-ordinated. What is the proper place of the mathematician in such a team? He should not be there as a problem solver; that is not his job, but the job of a machine. He should be there to formulate problems, to analyse relations, to strip off the superficial flesh and lay bare the essential structure. Fry illustrates this by reference to the central position occupied by mathematicians in the 'Nike' project, and draws the inference that industry requires mathematicians of the highest class to serve as superior consultants in planning operations; they are not to be called in merely to solve petty problems. To train such mathematicians, teachers must first understand the requirements; secondly, they must economize in time, so that training does not consume the fruitful years of the young mathematician. Fry suggests that algebra might be taught along with or even before arithmetic, that calculus and complex variable could be introduced in the ninth school-year, and that this could be done without any increase in the time allotted to mathematics in the schools. He admits that this is not an easy programme; many teachers in Britain favour the early introduction of calculus, but few would advocate any serious study of algebra before a firm grasp of arithmetic had been ensured.

The Need for Capital Investment in British Industry

In an article on "The Capital Question", in the May issue of the *Westminster Bank Review*, Mr. Graham Hutton stresses the need for more industrial capital in Great Britain; he argues that a substantial expansion of savings is needed, a severe reduction in 'investment' in public apparatus to provide consumers' services or durable goods, and a large increase in real investment in productive equipment and services, whether State or privately owned. Governments, he continues, have not looked carefully enough at the amounts and kinds of capital needed by Britain in its post-war situation, in which the population over the age of sixty is increasing faster than in any other industrialized nation, the birth-rate steadily falling, the money-income level rising annually faster than output and productivity, and in which the highest personal taxation on higher earnings in the Western world and the fastest inflation have redistributed incomes in favour of mass consumption rather than mass saving, so that there has been too little net personal saving in the decade. During the seven years 1948–56, capital formation for transport and communications represented nearly 12 per cent of the total, but contributed only 8 per cent to national output, and capital has not yet begun to be spent for more than maintenance (if that) of roads and railways. Manufacturing industry, providing 94 per cent of exports and nearly 40 per cent of output, only received 25 per cent of gross capital and had its capital programmes cut in each of the four post-war economic crises. On an average over the seven years, public enterprises received broadly two-thirds of all capital formation, and private enterprise, which provides all the exports and 75–80 per cent of output, only one-third, if that. Moreover, since 1948 the crude index of output against employment in manufacturing has risen 9 per cent more in France than in Britain, and 100 per cent more in West Germany and Japan, and Mr. Graham Hutton asserts that more hours a week or year are actually worked in Britain than in any of these countries. On an average, for British male adults a full working day in industry is longer than that for industrial workers in the United States, and the material return roughly one-half the American worker's real earnings.

Muelleria: a New Herbarium Journal

As Mr. A. W. Jessep, the director and government botanist at the Melbourne Botanic Gardens and National Herbarium, has pointed out, the National Herbarium of Victoria is the oldest and most extensive repository of Australasian herbarium material. It contains approximately one and a half million numbers of botanical specimens—evidence of the floristic richness of this great region. The adjacent Melbourne Botanic Gardens also support very rich and important collections. A new journal, *Muelleria* (1, No. 1 (August 1955); published by the Botanic Gardens and National Herbarium, Melbourne), which is named after the first government botanist of Victoria, F. J. H. Mueller—a man of great distinction whose work began a century ago—is intended primarily as a medium for the publication of botanical monographs, descriptions of new species and taxonomic studies generally, horticultural papers, and other botanical matters of general interest to professional and amateur botanists. In short, as the sub-title indicates, it will be an *Australian Journal of Botany*. As Prof. J. S. Turner rightly points out in a foreword, systematic botany is important, and, indeed, occupies a fundamental place, in contemporary research in agriculture, horticulture and forestry. The journal is edited by Mr. J. H. Williams, and the first issue contains notes and descriptions of a variety of new species of flowering plants and of cryptogams, and historical and bibliographical matter.

Journal of the Textile Machinery Society of Japan

The Textile Machinery Society of Japan is an organization formed for the purpose of advancing knowledge and technique in textile processing. It is a professional organization apparently similar in general structure to the Textile Institute in Britain. The Society publishes a monthly *Journal* in Japanese and, in 1955, decided to publish an English edition containing translations of articles which are considered to be of international interest. Judging from the first two issues (1, Nos. 1 and 2 (March and November 1955); from the Society at 28, 2-Bancho, Namba Shinchi, Minami-ku, Osaka; 10*s*. per copy), the scope of the new *Journal* appears to be wide, covering all the textile fibres, and all stages of textile processing. The papers cover general topics, articles on textile machines and scientific research. The technological and scientific papers are of a standard similar to those published by the Textile Institute. The Society also arranges public lectures, seminars and visits, and it is proposed to publish reports on some of these activities in future issues of the English edition. Each number contains about seventy pages, of quarto size, with good printing and diagrams and very readable English translations of the original papers. They also contain some seventy pages of Japanese textile advertisements, but these are kept at the back of the publication and do not impair the reading of the papers.

Nutritive Aspects of Preserved Food

International conferences can be very stimulating affairs for those who attend, and the discussions, in particular, often open up entirely new lines of thought. Publication of the proceedings can extend the stimulus to a much wider circle of workers, but only if publication follows close on the heels of the conference itself. All too often there is a delay of a year or more, by which time the material in the papers themselves has staled, and suggestions for further lines of inquiry have already been followed up. The proceedings of the symposium on nutritive aspects of preserved food, held in the Swedish Institute for Food Preservation Research, Gothenburg, during October 1954 (pp. 173; Publication No. 115 of S.I.K., Göteborg, 1956; 30 kr.), have been published approximately eighteen months after the conference took place; despite this delay, many of the papers are still badly in need of editing, the English sometimes being so poor that a sentence must be read several times over before the meaning can be grasped. The papers dealt with various aspects of nutrition and food technology and were presented by delegates from half-a-dozen different countries; they range from well-documented scientific studies to uncritical generalities put forward with insufficient and unsubstantiated evidence. The main use of the publication now lies in the review articles by Prof. G. Borgström (nutrition and food technology), Prof. R. A. Gortner (recent progress in the field of nutrition) and Prof. A. C. Frazer (the control of the use of chemical aids in food processing), and the evidence provided by the other papers about different lines of work being followed by different countries in 1954.

Bird Collection at Birmingham Museum and Art Gallery

The collection of British nesting birds in the Natural History Department of Birmingham Museum and Art Gallery commemorates in part the eminent public services of the late Alderman C. G. Beale, first vice-chancellor of the University and four times Lord Mayor of Birmingham. Funds provided by public subscription enabled work to be started in April 1913, and in May 1920 the memorial, encompassing forty-two nesting groups of common British species, was complete. Wherever possible, each nesting site was removed bodily from its surroundings, carefully preserved and reassembled for display. Every effort was made to secure the original parent birds, their eggs and their young. In the few instances where modelling became necessary, the original surroundings were photographed, measured, described and accurately reproduced. The greatest possible care was constantly taken by the taxidermists to give a faithful presentation of the various nesting groups, so that the collection is now rightly regarded as one of the best of its kind. A booklet describing the collection has been issued by the Museum (price 2*s*.), and photographic postcards of most of the groups in the collection are also available (price 4*d*. each).

Tracer Techniques in the Study of Host–Parasite Relationships

The accumulation of radioactive substances at loci of infection of some facultative and obligate fungal parasites and of tobacco mosaic virus has been investigated by M. Shaw and D. J. Samborski (*Canad. J. Bot.*, 34, 3, 389; 1956). Excised, parasitized leaves were placed with their bases in radioactive solutions or exposed to radioactive carbon dioxide, and the uptake and distribution of the tracers followed by autoradiography. Carbon dioxide and twenty other carbon compounds, including sugars, amino- and organic acids, phenols, and indoleacetic acid, and/or their metabolic products, as well as phosphate and calcium, accumulated strongly at uredial and conidial loci of the obligate parasites *Puccinia* and *Erysiphe* respectively. An accumulation of glucose, which occurred in the host tissue at the sites of mildew colonies on leaves from which the ectoparasitic fungal mycelium had been removed, ran parallel with the respiration-rate and increased progressively with the development of the parasites. It was inhibited by sulphur dust (with mildew), sodium azide, 2,4-dinitrophenol and, reversibly, by anaerobiosis, and was therefore dependent on aerobic respiration. On the other hand, the tracers did not accumulate within senescent rust and mildew colonies or within the necrotic lesions produced by bacterial and fungal parasites which kill the tissues of their hosts. Radioactive glucose did not, but calcium and phosphate did, accumulate within young local lesions of tobacco mosaic virus on *Nicotiana*. The tracers did not enter dead areas on mechanically wounded leaves, and only accumulated at fresh wounds under conditions conducive to a high rate of water-loss from the damaged surface.

The Soul in a Primitive Society

In his Fraser Lecture for 1955, given under the title "The Fate of the Soul" (Cambridge: At the University Press, 1955; 2*s*. 6*d*.), Prof. Raymond Firth returns to a subject examined by Sir James Fraser in his "Belief in Immortality and the Worship of the Dead". Firth's approach is, however, functional and not ethnological, as was Fraser's. His interest lies in these beliefs in terms of their social functions and, in support of his argument, he examines the eschatological beliefs of a particular society, Tikopia, relating them to its social structure and organization, with particular reference to the changing religious system. His conclusion is that the framework of ideas about the fate of the soul is in many respects a framework of ideas about the state of society, and that they are concerned primarily with emphasizing the continuity of society rather than the continuity of the individual personality.

Standard X-ray Diffraction Powder Patterns

The fifth in the series of "Standard X-ray Diffraction Powder Patterns", prepared by the National Bureau of Standards, Washington, D.C., has recently been published as Circular No. 539 of the Bureau (pp. 75. Washington, D.C.: Government Printing Office, 1955. 45 cents). In it, forty-five standard X-ray diffraction patterns are presented relating to two elements and forty-three inorganic compounds. The patterns are recommended to replace seventy-four cards in the card file of the American Society for Testing Materials, and, in addition, five compounds (cæsium chloroplatinate, cæsium chlorostannate, germanium iodide, rubidium chloroplatinate and thallium chloroplatinate), which are not represented in the file, are included. The experimental procedure used for obtaining the patterns and the general plan of the reports are the same as those in the volumes previous to Circular 539. The patterns are of use in many applications, but primarily for the identification of unknown crystalline materials. The samples used were of exceptionally high purity, and the patterns were made with a Geiger-counter X-ray diffractometer. The new publication concludes with a cumulative index to Vols. 1–5; but it is emphasized that further work on the programme is in progress, and it is anticipated that additional volumes in the series will be issued.

Professional Engineers Appointments Bureau: Report for 1955

The report for 1955 of the Professional Engineers Appointments Bureau (9 Victoria Street, London, S.W.1) shows that there was no significant change in the numbers of civil, mechanical and electrical engineers registering with the Bureau, but the number of vacancies notified increased by 20 per cent. The total placings rose by 15 per cent above the figure for last year, but the more rigid specification of requirements laid down both by those registered and by prospective employers tended to reduce the field of selection. More of the placings were for senior appointments and fewer for junior posts. More employers and engineers approach the Bureau informally to discuss their problems and to review the general employment market. In general, firms which are rapidly expanding are having great difficulty in securing staff who have the particular specialized experience that is now required in many posts in industry.

Directory of British Insecticides, Fungicides and Weedkillers

THE Association of British Insecticide Manufacturers has recently published the third edition (1956) of its "Directory" of British insecticides, fungicides and weedkillers (pp. 128; from the Association, London, 1956). In addition to a directory of member firms of the Association, the publication provides information on the chemicals available for the control of insects, fungi and weeds, and where they may be obtained. Proprietary and trade names are also given, with an indication of the use of each proprietary product. Information is also given on where to obtain accessory materials such as wetters, spreaders and stickers and the machines for applying the chemicals. The Directory should prove most useful to all those interested in the supply and use of chemicals for pest control. It is fully indexed.

Library of the University of Leeds: Report for 1954–55

THE annual report of the librarian of the University of Leeds for the session 1954–55 (pp. 12; from the Brotherton Library, Leeds) records holdings on June 30, 1955, of 389,118 volumes and 163,866 pamphlets. Of these, 279,625 volumes and 110,988 pamphlets are in the Brotherton Library, the corresponding figures for the Medical Library being 28,209 and 3,645, respectively; for the Agricultural Library, 9,457 and 25,980; and for the Textile Library, 5,225 and 900. Accessions for the year totalled 9,859 volumes, 2,355 pamphlets and 25,762 periodical parts, a decrease of 7 per cent. Loans to readers totalled 94,531, an increase of 4 per cent, and inter-library loans totalled 4,218, the books borrowed increasing by 22 per cent to 1,510 and those lent by 2 per cent to 2,708. Detailed consideration was given during the year to regulations for the consultation and loan of theses, and there was no difficulty in accepting the general desirability of making available the work contained in theses of the University. Subject to the desire to protect the author and obviate premature publication prejudicial both to the author himself and the department concerned, every effort will be made to facilitate the proper use of thesis material by qualified readers both in the University and outside it. The Council of the University has also generally approved the proposal that graduate members of the library staff should, in suitable circumstances, be given periods of up to three months of leave for research. Staff changes have been largely responsible for a 34 per cent fall in the cataloguing output, but the insistent demands of the reading room and the need of assistance in the sectional libraries have also contributed to this.

Oversea Service Division, Colonial Office

THE following appointments have recently been made in the Oversea Service Division, Colonial Office: W. H. Edwards (agricultural officer, Uganda), assistant director of agriculture (field), Uganda; A. M. M. Rees (agricultural economist, Northern Rhodesia), agricultural economist, Jamaica; T. A. A. Talbot (assistant agricultural officer, Kenya), agricultural officer, Kenya; J. D. Yelf (agricultural officer, Northern Rhodesia), senior agricultural officer, Fiji; P. F. Burgess (assistant conservator of forests, Federation of Malaya), senior assistant conservator of forests, North Borneo; F. G. Harper (conservator of forests, Gold Coast), deputy chief conservator of forests, Gold Coast; Dr. J. R. Audy (medical officer, Institute for Medical Research, Kuala Lumpur, Federation of Malaya), specialist (grade B), senior virus research officer (superscale H), Federation of Malaya; E. F. Duck (government pathologist, Hong Kong), pathologist, General Hospital, Bahamas; M. P. Hutchinson (research epidemiologist, West African Institute for Trypanosomiasis Research), deputy director, West African Institute for Trypanosomiasis Research); Miss V. Suter (scientific officer, Colonial Microbiological Research Unit, Trinidad), senior scientific officer, Colonial Microbiological Research Unit, Trinidad; P. T. Walker (scientific officer, Colonial Insecticides Research Unit, Tanganyika), senior scientific officer, Colonial Insecticides Research Unit, Tanganyika; A. E. Dorman (provincial veterinary officer, Kenya), assistant director of veterinary services, Kenya; K. J. R. Maclennan (senior veterinary officer, Northern Region, Nigeria), principal veterinary officer, Northern Region, Nigeria; W. Plowright (veterinary research officer, Federation of Nigeria), veterinary research officer (pathologist), East African Veterinary Research Organization, East Africa High Commission; A. J. Bearman (principal, School of Pharmacy, Federation of Nigeria), chief pharmacist, Federation of Nigeria; E. Cundiff, agricultural officer, British Guiana; C. L. M. van Eynatten, scientific officer, plant breeder, Maize Rust Research Unit, Federation of Nigeria; K. Paijmans, assistant conservator of forests, Gold Coast; M. J. Fleuty, geologist, Uganda; J. D. Arneaud, pathologist (grade A), Trinidad; A. T. Brough, statistician, East Africa High Commission; G. D. Phillips, veterinary research officer, East Africa High Commission.

Announcements

DR. T. K. WALKER, reader in fermentation processes in the Faculty of Technology, University of Manchester, has been given the status of professor, with the title of professor of industrial biochemistry, in the University.

IN the article entitled "Tube Investments Research Laboratories" in *Nature* of July 14, p. 60, it should have been stated that the cobalt irradiation equipment was designed and built by Nuclear Engineering, Ltd., of Greenwich Metal Works, London, S.E.7.

Tubercle, the journal of the British Tuberculosis Association, has, since the beginning of this year, appeared two-monthly in an enlarged size, with an improved format. In addition to tuberculosis, the journal deals with respiratory disease in general and related infections, for example, leprosy; laboratory as well as clinical and epidemiological aspects are included. Dr. J. R. Bignall has recently been made editor and a new Editorial Committee appointed.

IN 1955, the Muséum d'Histoire Naturelle, Paris, set up an exhibition to direct attention to the importance of safeguarding natural resources and to illustrate the damage done to animal and plant life and to the soil itself. The nucleus of this exhibition is now being sent to a number of different countries. In Britain, under arrangements made by the Society of the Men of the Trees, it is being shown in the Senate House of the University of Cambridge during July 18–31; and it is hoped that it will be shown afterwards in London.

ERRATUM. In the communication entitled "Origin of the Common Wild Oat, *Avena fatua* L.", by D. J. Griffiths and T. D. Johnston (*Nature*, July 14, p. 99), Fig. 1 has been inadvertently printed upside-down.

A NUMERICAL CALCULATION OF THE GENERAL CIRCULATION OF THE ATMOSPHERE

MUCH work has been done in recent years in the calculation of changes in the wind and temperature of the atmosphere from hydrodynamic and thermodynamic theory. The equations are non-linear partial differential ones and, moreover, the atmosphere is a turbulent fluid of variable viscosity, subject to heating and cooling by radiation and changes of state of water and retarded at the ground by surface friction. It is now well realized that only by applying dynamical theory to the atmosphere can serious progress be made, and the method is the classical scientific one of studying simplified model atmospheres and comparing the results with observations.

Hitherto, the models used have not allowed for friction or for heating and cooling by radiation. In such models, temperature changes adiabatically only in association with pressure. Now, however, in a paper in the April number of the *Quarterly Journal of the Royal Meteorological Society*, which has since been awarded the first Napier Shaw Memorial Prize, N. A. Phillips, of the Institute of Advanced Study, Princeton, describes an experiment in the numerical calculation of atmospheric changes allowing for friction and non-adiabatic heating. Phillips starts with an atmosphere at rest relative to the Earth and at a uniform temperature, and calculates developments. The calculation is based on approximate equations of motion and thermodynamic energy-change. The upper atmosphere is represented by the 250-mb. level and the lower by the 750-mb. one. The surface of the Earth and its associated friction and zero vertical velocity is everywhere at 1,000 mb. The divergence at the 750-mb. level is necessarily equal and opposite in sign to that at 250 mb. Important assumptions are: hydrostatic equilibrium in the vertical; geostrophic wind except in one term of the equations; constancy of the Coriolis parameter and its derivative with respect to latitude; and constancy with height of the stability parameter $(\theta_1-\theta_3)/\theta_2$, where θ_1, θ_2, θ_3 are potential temperatures at 250, 500 and 750 mb.

The atmosphere is supposed to be heated by radiation from the equator to latitude 45° and cooled from there to the pole at a rate independent of height but proportional to distance from latitude 45°. Friction at the ground and lateral and vertical diffusion are allowed for with reasonable assumptions. Empirical mean values are used for the various constants. The equations of motion and energy are reduced to finite difference form and solved on an electronic computer for values at a grid of points at intervals of 625 km. latitudinally and 375 km. longitudinally.

Calculations were made over a rectangular area of width 6,000 km. from west to east and depth 10,000 km. from south to north. The boundary conditions were: (*a*) identity of values of all elements at a given latitude on the east and west boundaries; (*b*) zero normal geostrophic wind and zero disturbed geostrophic vorticity on the south and north boundaries.

Starting from the state of rest and uniform temperature and with the restraint that the flow was independent of longitude, the flow and temperature patterns were first computed step by step for a period of 130 days, by the end of which time there were a nearly uniform fall of temperature from equator to pole, broad westerly winds with the reasonable maximum of 36·3 m./sec. in middle latitudes at 250 mb., a weak easterly wind (order 1 m./sec.) at the surface and a minute southerly wind at 250 mb. On this circulation there was then superimposed a small random flow initially independent of height but varying horizontally in a random manner, and the development again computed. This culminated in the formation of a large central depression moving eastward at about 1,800 km./day and having features, such as isobars like those at fronts, corresponding to real depressions and with a marked westerly jet-stream and a mean poleward flux of energy.

Considering the assumptions made, the result must be regarded as a remarkably close approximation to reality, and the paper is one to be read by all meteorologists and mathematicians interested in that most difficult problem of hydrodynamics, the circulation of the atmosphere.

INDUSTRIAL APPLICATIONS OF THE ELECTRON MICROSCOPE

A CONFERENCE on "Industrial Applications of the Electron Microscope", organized by l'Association des Ingénieurs sortis de l'École de Liège, was held in Liège during May 2–5. Representatives of fourteen countries were present. The main part of the conference was devoted to the study of metals and one session to chemical problems. Throughout the conference it was noteworthy that, although applications of the electron microscope were described in all papers, in few was the microscope given undue prominence. It appears that the electron microscope is now being used as just one more piece of apparatus in the laboratory. The results obtained are valuable and, in many cases, not obtainable in any other way; but the time has passed when problems are being sought specifically to find a use for the electron microscope.

Dr. L. Habraken (Centre National de Recherches Métallurgiques, Liège) welcomed the visitors on behalf of the Association and of the C.N.R.M. and introduced the first speaker, Dr. J. B. Le Poole (Technisch Hoogeschool, Delft) who traced the history and probable future of electron microscopes. Early electron microscopes were merely optical analogues of light microscopes; the resolution obtainable to-day had only been achieved when methods of lens correction specifically applicable to electrons and not to light had been applied. New methods in the optics of charged particles, in particular, devices using velocity selection, made it possible to go further and use the electron microscope as a direct means of chemical analysis of the specimen. Prof. C. Fert (University of Toulouse) described the present state of his researches on the direct examination of metallic surfaces by the reflexion electron microscope. Resolution of 300 A. is now obtained and the distortion of the image resulting from the small angle of viewing has been eliminated, partly by viewing at larger angles, partly by the use of cylindrical lenses to equalize the magnification in directions parallel to and perpendicular to the beam. A paper from Prof. G. Mollenstedt (University of Tübingen) and read by Dr. H. Mahl described a new form of microscope which depends on focusing electrons released from metallic specimens by ionic bombardment. Using it, bulk metallic specimens can be examined with a resolution of 500 A. The theoretical limit of resolution is 100 A., and specimens can be examined at any temperature, for example, during the course of phase transformations.

One session was devoted to new techniques in metallography. There were no papers describing yet more replica techniques. Instead, all contributors dealt with methods of making use of the full resolving power of the electron microscope instead of the many times inferior resolving power of replicas. The highest resolving power (10 A.) was claimed by Prof. R. Castaing (University of Toulouse) for his thin-specimen techniques. Metal foils are first etched, then bombarded cathodically until they are thin enough to transmit electrons. Using specimens prepared thus, it has been possible to study the early stages of precipitation in aluminium – 4 per cent copper alloys, including observations of the formation of Guinier–Preston zones. Thin films had also been studied by Dr. K. Ito (Electron Optical Laboratory, Tokyo), who had prepared his metal films by evaporation. The Japanese workers had constructed small furnaces and cryostats in which these films could be heated and cooled while actually under observation in the electron microscope. The stages in the precipitation of the various intermetallic phases from a 50–50 aluminium–copper alloy had been followed at high temperatures, and the crystallization of mercury had been observed at −180° C. Mme. Stoyanova (Electron Microscopy Laboratory of the Electronics Industry, Moscow) described how electron microscopy under dark-field conditions made possible the chemical identification of sub-microscopic and even sub-electron microscopic particles. In conjunction with the thin-film methods of Castaing and Ito, these dark-field techniques give most powerful methods of investigating the earliest stages of segregation of foreign atoms in metallic solid solution. Two papers from the Technical High School, Aachen, were devoted to the location and identification of fine precipitates in steels. In a new process described by Dr. H. Goosens, the specimen is etched until the precipitates stand out from the surface. A plastic film is then cast on the surface in order to hold the precipitates in position and finally the rest of the metal is etched away. By this means the actual precipitates can be examined free from the matrix but in their correct relative positions and at the highest resolution available in the electron microscope. Their chemical nature can likewise be determined by X-ray or electron diffraction. An application of this method to the study of grain-boundary inclusions was reported by Dr. H. K. Gorlich of the same laboratory, while a third paper describing the use of a similar technique was delivered by Dr. A. Schrader (Max Planck Institute, Dusseldorf), who had examined extremely fine precipitates in chromium–nickel–molybdenum steels, and followed the changes produced in them during creep.

Several invited papers reviewed the current position in the study of the relationship of microstructure to mechanical properties: Dr. J. Nutting (Metallurgical Laboratory, University of Cambridge), dealing with ferrous materials, showed that it was now possible to predict the creep properties of steels quickly by means of the electron microscope and without the necessity for lengthy creep tests at high temperatures. Creep resistance has been found to require the presence of highly refractory, very small (about 20 A.) particles highly dispersed in the matrix. Dr. A. Saulnier (Société Pechiney, Chambéry) explained how the strength of non-ferrous alloys were derived from the clustering of solute atoms into metastable aggregates with dimensions often less than 1/10 μ. In the aluminium alloys containing copper or magnesium, and also in various titanium alloys, these aggregates had been detected and identified by the electron microscope. Similar work in relation to the complex gas-turbine alloys containing nickel, copper, aluminium and titanium was reported by Dr. Y. Baillie (Office National d'Études et de Recherches Aéronautiques, Paris). Plastic deformation of pure metals was reviewed by Dr. A. F. Brown (University of Edinburgh). Present evidence obtained from electron microscope observations of the surface of pure metals conflicted with the results of other experiments, such as electrical resistance measurements, which aimed at studying the properties of the bulk of the material. Thus, experiments required to be devised by which the effects of plastic deformation could be detected under the surface of the metal. One such method based on the use of radioactive tracers was further developed in a paper by Prof. N. Feather, Dr. D. J. Shapland and Dr. A. F. Brown (University of Edinburgh), which described an electron optical method of improving the resolution of autoradiography.

A study of fracture surfaces had been systematically carried out by J. Plateau, G. Henry and Prof. C. Crussard (Institut de Recherches de la Sidérurgie, St. Germain-en-Laye), who presented micrographs showing the fine structure of brittle, ductile, intergranular and fatigue fracture surfaces. In ductile fracture it has sometimes been possible to trace the origin of the fracture to submicroscopic inclusions. Etching techniques of great delicacy had been employed by Dr. Wan Wijk (Metaalinstitut, Delft) to reveal the distribution of dislocations in pure iron and mild steel. It appears that the Cottrell atmospheres which surround the dislocation lines are either more or less susceptible to chemical attack than the surrounding matrix, depending on the nature of the impurities and the etchants. The surface of the metal is thus seen to be covered with a system of about 10^{10} tiny pits or mounds per cm.^{2}, giving the well-known 'orange peel' appearance usually observed after electrolytic polishing.

A complete session was devoted to the uses of the electron microscope in the chemical industry. The chief speaker was Dr. H. Mahl (Zeiss, Oberkochen), who reviewed the methods available and the results achieved in industrial quality control. Dr. J. J. Fripiat (University of Louvain) described how the electron microscope was assisting conventional techniques of soil analysis. Other notable contributions to the conference included a brief description by Prof. G. M. Kushnir (Electron Microscopy Laboratory of the Electronics Industry, Moscow) of the various electron microscopes and electron diffractographs manufactured in the U.S.S.R. All types are available, including electrostatic instruments and reflexion instruments, the best resolution commercially available being about 20 A. There are about 350 electron microscopes in use. From the United States, Dr. W. L. Grube (General Motors Corporation, Detroit) summarized the work of the committee of the American Society for Testing Materials, which is investigating the electron microstructure of steel. It is intended to collect complete metallographic evidence of the structure of steels as seen in the electron microscope at highest resolving power, and thus to encourage the use of the results in steel works laboratories for ordinary quality control.

The final session included a visit to the laboratories of the Centre National de Recherches Metallurgiques. These richly equipped laboratories have been built since 1945 on the site and using the external architecture of an old abbey. They have already made notable contributions to metallurgy, particularly to the knowledge of steels. A. F. Brown

HYPOTENSIVE DRUGS AND THE CONTROL OF VASCULAR TONE IN HYPERTENSION

UNDER the auspices of the Co-ordinating Committee for Symposia on Drug Action, a symposium on hypotensive drugs and the control of vascular tone in hypertension was held at the Wellcome Building, London, N.W.1, during April 5 and 6. The meeting was organized by a committee representing the British Pharmacological Society, the Physiological Society, the Section of Experimental Medicine and Therapeutics of the Royal Society of Medicine, the Fine Chemicals Group of the Society of Chemical Industry, the Biochemical Society, the Pharmaceutical Society, the Association of Anæsthetists and the Society for Endocrinology.

The conference was opened by Sir Charles Harington, chairman of the Co-ordinating Committee for Symposia on Drug Action, who briefly reviewed the function of the Committee in organizing symposia on subjects which are of interest to several different societies. He expressed appreciation of the generous hospitality of the Wellcome Foundation, Ltd., the contributions of which to knowledge of the subject extend over many years. He felt particular pleasure in opening the symposium because of the work of the late Dr. Harold King at the National Institute for Medical Research on the development of the methonium compounds and on the elucidation of the chemical structure of D-tubocurarine. After referring to the work of Dr. H. R. Ing, Dr. Zaimis and others, he invited Prof. F. Bergel to take the chair at the session on "Chemical and Biochemical Aspects".

The first speaker was Dr. H. R. Ing (Oxford), who discussed "Structure-action Relationships of Hypotensive Drugs". Of the veratrum alkaloids, the most potent are the ester-alkaloids, which retard the heart-rate and respiration by interference with the afferent nerve endings in the lungs. The vasodilator amidines behave similarly and, of these, phenyldiguanide, its *o*-chloro derivative, and 2-α-naphthylethyl*iso*thiourea are especially potent. Compounds of similar type which have found clinical application are tolazoline, hydralazine (1-hydrazinophthalazine), and phentolamine, all of which produce rapid but transient competitive inhibition of the actions of adrenaline and noradrenaline.

Dibenamine (N-[2-chloroethyl]diphenylamine) exhibits a non-competitive inhibition. The onset of activity is slow and, though the blockade can be overcome in the early stages, its action becomes permanent. It is suggested that initial adsorption at an active centre, possibly involving intramolecular alkylation, is followed by reaction of the ethyleneimmonium ion with groups such as —SH, —OH, or —NH_2.

The *Rauwolfia* alkaloids, for example, reserpine, deserpidine and reserpinine, also show a slow onset of action. Little is known of their structure–action relationships.

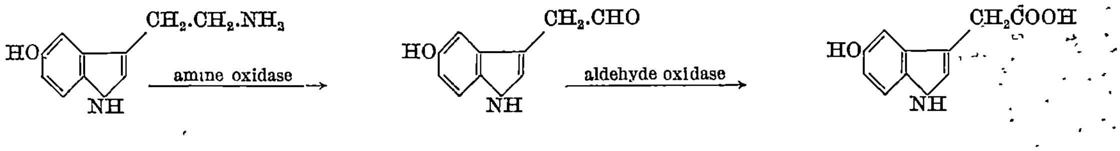
Ganglionic stimulating and blocking activity is shown by a considerable number of secondary, tertiary and quaternary bases. Several quaternary trimethylammonium bases exhibit stimulatory activity, while their triethyl analogues are inhibitors. The *bis*-quaternary ammonium bases, such as hexamethonium and pentolinium, have a purely blocking action. The end-groups vary in potency with differences in chain-length. $Me_2Et\overset{+}{N}.CH_2.CH_2.OCH_2.CH_2\overset{+}{N}Et_3$ is more effective as a blocking agent than corresponding symmetrical compounds. The blocking agents are frequently of value in hypertension when administered parenterally. It is probable that the quaternary bases will eventually be supplanted by tertiary or *bis*-tertiary compounds, which are usually better absorbed from the alimentary canal. These are frequently stimulatory in small doses, but inhibitory in larger amounts.

Dr. H Blaschko (Oxford) then presented a paper entitled "Biochemical Principles in relation to Hypotensive Drug Action". After explaining that the effectiveness of a given compound is governed by its concentration in the neighbourhood of the receptor centre, the biosynthetic route to adrenaline was traced. The metabolic pathway appears to be as follows:

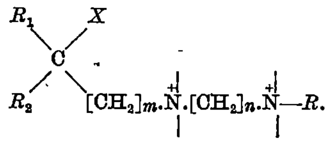
Tyrosine → 3 : 4-dihydroxyphenylalanine (DOPA) → 'Dopamine' → noradrenaline → adrenaline.

It has been established that chromaffin tissue is rich in DOPA decarboxylase, which controls the second stage of this route, and also that in various systems about 6 per cent of 'Dopamine' can be converted into noradrenaline. Inhibitors of DOPA decarboxylase have been investigated, but it seems that studies of 'Dopamine' dehydrogenase might offer a more hopeful approach.

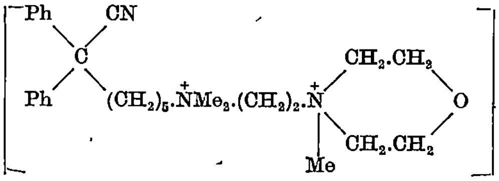
Reserpine has been shown to stimulate the release of 5-hydroxytryptamine (serotonin) from mitochondria. This substance then undergoes degradation to 5-hydroxyindoleacetic acid, which is excreted in the urine:



The discussion was opened by Mr. J. W. Billinghurst (Beckenham), who summarized the results of a search for new ganglionic blocking agents in the series:



As the value of m is increased to a maximum of 6, the duration of the effect (mydriasis in mice) is prolonged. One of the most interesting compounds from the clinical point of view is:



(365C54)

Prof. H. McIlwain (London) pointed out that the diversities of action of the compounds mentioned during the session are a hopeful sign, and illustrated his point by reference to the many effects of protoveratrine. In reply to Dr. H. J. Barber, who asked if the nature of the anion has any effect on the activity of the ganglionic blocking agent, Dr. M. Harington said that the anion appears to influence only the rate of absorption of the drug.

The second session was devoted to "The Pharmacology of Hypotensive Drugs", under the chairmanship of Prof. J. H. Burn. The first paper was by Dr. J. Tripod (Basle) on "Some Pharmacological Differences between Hypotensive Drugs, with special reference to Hydralazine and Reserpine". He discussed the differentiation of hypotensive drugs according to their specific antagonisms of a variety of vasoconstrictor agents. The fall in blood pressure produced by hydralazine is abolished by previous incubation with rabbit serum. Veratrine and reserpine, on the other hand, are not affected by such treatment.

During discussion it was stated that the inactivation of hydralazine is not due to hydrazone formation. While protein hydrolysates cause inhibition, no amino-acids are found to produce this effect.

Dr. Marthe Vogt (Edinburgh) then discussed "Theories concerning the Site and Mode of Action of Reserpine". The central effects of reserpine, for example, sedation, are mediated through the hypothalamus, but this is not the only site of action. After 1·5–2 mgm./kgm. in rabbits, the encephalogram shows the disappearance of the high-voltage slow waves which are normally seen in sleep or after barbiturates. The effect is different from that of barbiturates, for the animals can be roused. The chief peripheral effect is flushing, that is, dilatation of the capillaries, which is independent of the central nervous system.

The long latent period of action ($\frac{1}{2}$–1 hr.) implies that some metabolite is responsible for the effects of reserpine, but no products of hydrolysis have been shown to have any pharmacological action. It has been suggested that it causes release of 5-hydroxytryptamine (5-HT) from body stores; thus the urinary output of 5-hydroxyindoleacetic acid is increased, and the 5-HT stores in the argentaffin cells, the brain and the platelets are diminished after the administration of reserpine. Furthermore, 5-HT prolongs barbiturate-induced sleep in mice, and all known *Rauwolfia* alkaloids showing a central effect affect the release of 5-HT. Thus, it would appear that depletion of the 5-HT stores is responsible for the effects of reserpine; but this cannot be the case since amphetamine also causes a fall in 5-HT storage without inducing sedation. Moreover, patients with carcinoidosis who have very high circulating levels of 5-HT do not exhibit disturbances of the central nervous system.

Prof. F. Smirk described experiments which provided evidence that reserpine might also have a peripheral effect, and Prof. J. H. Burn asked if 5-HT is known to be present in sympathetic ganglia. In reply, Dr. Vogt said she has been unable to detect it, but its presence cannot be excluded.

Dr. W. S. Peart (London) then presented a paper on "Substances Antagonistic to Adrenaline and Noradrenaline", which dealt with the action of the β-haloalkylamines, dibenamine and dibenylene. The latter is active orally. Dealing with the theory that these substances owe their activity to the ethyleneimmonium ion, he pointed out that sodium thiosulphate blocks their action by combining with the ion, but as it also combines with the haloalkylamine, this evidence is inconclusive.

In man the main effects are postural hypotension, meiosis and vasodilatation in the skin. Side effects observed include nasal congestion, nausea and vomiting. His main conclusion was that these substances, which are very potent blocking agents for sympathomimetic effects, have an action which is entirely peripheral, that is, in the arterial wall.

In discussion, Dr. A. C. Dornhorst said that a marked adrenolytic effect can be obtained in man with a dose of 25·mgm. dibenylene, but he is not sure that no effect is produced on the central nervous system. Dr. Ginsburg said she has found that chlorpromazine is more effective against noradrenaline than against adrenaline, but dibenylene is more effective than chlorpromazine against both. Dr. Chapman and Dr. Graham described the results with haloalkylamines. Using purified stable salts of the immonium ions, they showed these to be the active species—a conclusion accepted by Dr. Peart.

Dr. J. G. Widdicombe (London), speaking on "Veratrum Alkaloids", said that they act by eliciting the Bezold reflex, the sensory receptors for which lie in the ventricular muscle of the heart: there was also some evidence for a direct central action. Intravenous injection produces bradycardia and a fall in blood pressure due to peripheral vasodilatation. The cardiovascular effect appears to be mediated by the vagus, since that can be abolished by cutting this nerve. The ventriculo-pressor and pulmonary-depressor reflexes also appear to be involved, but different mechanisms seem to operate in different species.

Dr. Eleanor Zaimis (London) then reviewed "Ganglionic Blocking Substances". A study of the quaternary bases, 'Ecolid' and 139C55, and the secondary amine, mecamylamine, showed all three to exert a prolonged action, especially 'Ecolid', but mecamylamine showed better absorption. Dealing with tolerance to the methonium drugs, she pointed out that patients vary in the rates at which tolerance is developed. It appears to bear no relation to the severity of the disease or to its duration. Repetition of administration of the drugs increases the paralytic effect on the nictitating membrane of the cat; but blood pressure effects tend to be reduced. Hexamethonium appears to potentiate the action of adrenaline. These observations suggest that tolerance may be due to increasing sensitivity of the end organ to adrenaline and not to lack of effect of the methonium compound on the block.

Dr. A. F. Green, opening the general discussion, referred to the new compounds, 139C55 and 356C54, which are more effective than the -onium compounds in increasing pupil diameter, and have a much longer period of action. The degree of ganglionic blockade depends upon the number of stimuli passing; thus different functions, for example, blood pressure, inhibition of gastric secretion, delay in gastric emptying, may be affected to different extents. Dr. M. Harington described observations on patients under controlled conditions showing that the action of hexamethonium might be potentiated after reserpine.

In opening the third session, "Clinical Applications of Hypotensive Drugs", the chairman, Prof. J. McMichael, apologized for the absence of Prof. Pickering and welcomed Prof. F. Smirk.

The first paper, "Results of Methonium Treatment in Malignant Hypertension: Five Years' Follow-up", was by Prof. J. McMichael (London). Hypertensive patients have been classified into four groups according to the changes occurring in the fundus oculi, their survival being directly related to the extent of such changes. The value of the methonium drugs has been assessed in patients in the worst of these categories, group IV. It was originally planned to use half the patients as controls; but this proved impossible because the improvements in the treated series were so good that treatment could not be withheld from the others.

Hexamethonium has now been replaced by pentolinium given by subcutaneous injection three times daily, but it seems that equally satisfactory results can be obtained by giving a double dose at night and an afternoon injection. If 0·1 mgm. reserpine is given thrice daily, smaller doses of the methonium drugs can be used, with a consequent reduction in the side effects.

Survival depends upon the extent of renal damage, but if the blood urea is not greater than 60 mgm. per 100 ml. there is an even chance of the patient being alive after five years. Of the symptoms associated with hypertension, methonium treatment rapidly clears the retinitis and the headache disappears; the size of the heart diminishes and signs of heart failure are less obvious; attacks of encephalopathy are usually diminished, but the drugs have no influence on hemiplegia or arteriosclerosis.

Prof. F. Smirk (Dunedin) followed with a paper on "Principles and Details in Hypotensive Therapy", in which he said that the aim must be to reduce the blood pressure to normal, but the presence of other lesions may not permit this to be achieved. Impressive reductions in the mortality of hypertensive patients have been obtained using a combination of reserpine and pentolinium by mouth.

The main considerations to be taken into account in initiating hypotensive therapy include: (1) posture: the drugs are more effective when the patient is standing than when lying down; (2) meticulous adjustment of the dose to bring the blood pressure down to 120/80 mm. when maximum effect is exerted; (3) combination of drugs, for example, reserpine (0·5 mgm.) and ganglionic blocking agent; and (4) frequent checks of the response of blood pressure to the doses given throughout the period of treatment using all-day tests.

In reply to Prof. C. Wilson, Prof. Smirk said that side effects are more troublesome in the malignant phase of the disease. If treatment is pressed too hard the patient may abandon it. Some relief may be obtained by trying variations in the drugs used. Dr. Gilchrist asked whether, after obtaining an initial response with intravenous pentolinium in acute cardiac asthma, digitalis provided adequate continuation, whether pentolinium could successfully be combined with hydralazine, and whether pentolinium exacerbated symptoms in a uræmic patient? Prof. Smirk replied that their practice was not to use digitalis, mersalyl, etc., in conjunction with hypotensive drugs, since after intravenous hexamethonium a dramatic response is obtained in 1–1½ minutes. Renal disease is not affected, except indirectly through improvement of the circulation. Dr. B. Hood said that the side effects of hydralazine are unpleasant, but when combined with the ganglionic blocking agents, an enhanced response is obtained.

The last paper of the third session was "Hypotensive Drugs: Clinical Evaluation under Controlled Conditions", by Dr. G. A. Perera (New York). No veratrum alkaloid proves effective unless the dosage is so high that unpleasant side effects are produced. In benign hypertension, pentolinium and hexamethonium have little therapeutic value, while the *Rauwolfia* alkaloids exert benefit by their sedative effects. In the accelerated phase, the *Rauwolfia* alkaloids are of little value, and pentolinium, while it lowers blood pressure, has no effect on renal failure. Hydralazine rarely produces improvement and may cause further renal damage.

Insufficient time has elapsed to assess life prolongation, but it seems that survival is prolonged when there is little kidney damage.

Of three thousand patients who underwent sympathectomy, 40 per cent survived five years. Drugs will probably not improve upon that figure.

Prof. C. Bartorelli (Milan) described his experiences with hexamethonium and reserpine, and Dr. B. Hood (Gothenburg) reported that 90 per cent of his hypertensive patients treated with a combination of reserpine, pentolinium and hydralazine were able to resume work. Prof. McMichael disagreed with Dr. Perera concerning surgical sympathectomy, which in his experience was never complete and seldom reduced blood pressure. A general discussion of the value of oral administration of methonium drugs then followed. Dr. Dornhurst supported Dr. Perera's plea that it is not possible at present to make a final evaluation of these drugs, and Dr. R. W. D. Turner deplored the promiscuous use of drugs in cases in which there was no evidence of hypertensive disease other than raised blood pressure.

The closing session was devoted to "The Control of Vascular Tone in Hypertension", with Prof. Clifford Wilson in the chair.

The first paper, on "Clinical and Experimental Indications", was presented by Prof. Clifford Wilson (London). Except in the case of phæochromocytoma, the primary cause of hypertension is not known. In this case an adrenal medullary tumour secretes an increased quantity of adrenaline and noradrenaline, the actions of which can be inhibited by sympathetic blockade. The blood pressure may remain high (established hypertension) even after surgical removal of the tumour. The symptoms of essential hypertension are all due to the high blood pressure and spontaneous reversals are rare. Sedation has no effect on the blood pressure. There is no evidence in support of the view that over-production of adrenaline or noradrenaline is responsible, and renal lesions have been excluded as the cause. Obesity increases the tendency, and women tolerate hypertension better than men.

When the renal arteries of rats are clipped, encephalopathy develops, but disappears on removal of the clips.

Whatever the primary cause of the raised blood pressure, when it persists new mechanisms arise leading to the malignant phase of the disease. It seems that some extra-renal factor which leads to the breakdown of renal control is involved.

The next paper was by Dr. B. Folkow (Gothenburg) on "Structural, Myogenic, Humoral and Nervous Factors controlling Peripheral Resistance". The resistance to blood flow of the vessels in the forearm was measured when these were fully dilated under conditions of ischæmia. This resistance is unchanged when the normal person is made acutely hypertensive with noradrenaline, but is increased in patients with essential hypertension. It appears that this may be due to a thickening of the vessel wall.

Dr. M. A. Floyer and Dr. J. M. Ledingham (London) then read papers on "Renal and Extra-renal Factors in Experimental Hypertension". Dr. Floyer described experiments on rats with one kidney clamped and the other removed, from which he concluded that some extra-renal factor under the control of the kidney is responsible. Dr. Ledingham produced evidence in support of the view that the adrenal cortex is involved.

In discussion, Dr. J. Conway (London) concluded that something other than spasm is the cause of increased peripheral resistance, and suggested that methonium drugs might enhance the effect of long-acting nitrites. Dr. R. S. Duff described the results of measurements of the blood flow in the hand under standard conditions, and found that hypertensives are more sensitive to adrenaline. Dr. W. S. Peart used the method of maximum heat elimination to assess the peripheral vasomotor tone. In phæochromocytoma this is much reduced but returns to normal after removal of the tumour, even if hypertension is not relieved.

THE MOTIONS OF THE OUTER PLANETS

FOR his George Darwin Lecture which he delivered last year to the Royal Astronomical Society, Prof. Dirk Brouwer chose for his subject "The Motions of the Outer Planets" (published in *Mon. Not. Roy. Astro. Soc.*, **115**, 3 (1955), and also, slightly condensed, in *The Observatory*, **75**, No. 886 (1955)). Prof. Brouwer discussed four topics : the masses of the outer planets ; accuracy of the numerical integration orbits ; classical planetary theory in rectangular co-ordinates ; and generalized planetary theory.

Masses of the outer planets. For numerical integration the mass of Pluto has been taken as 1/360,000 (the mass of the Sun is the unit throughout), and for the masses of Jupiter, Saturn, Uranus and Neptune those used by Newcomb and Hill have been adopted. A recent investigation by Hertz indicates that the mass of Saturn should be increased by 1 per cent, and from the perturbations of this planet on Jupiter he has obtained for the reciprocal of the mass of Saturn 3497·64 ± 0·27 p.e., which is in excellent agreement with the results derived from satellite orbits. The most comprehensive determination of the mass of Neptune is that made by Eichelberger and Newton from the observations of Triton, but the large difference between the results from visual and photographic observations suggests that there are systematic errors in both. During 1939–42 Alden made a series of photographic observations of Triton with the Yale telescope—at that time in Johannesburg—and the material is now being used at the Yale Observatory with the special object of a new determination of the mass of Neptune. Reference was made by Prof. Brouwer to other new work going on in the study of the satellites of Uranus and Saturn with the main object of finding more-accurate values of the masses of the planets, and preliminary steps for determining Jupiter's mass have been undertaken at the United States Naval Observatory, where observations of thirteen minor planets near the 2/resonance region are in progress. In deriving the mass of Pluto from observations of Uranus, the residuals for the pre-discovery observations are very large ; the result largely depends on Flamsteed's observations in 1712 and 1715, which are not accordant, and rejection of the latter, as favoured by Kourganoff, yields a mass of Pluto comparable with, or greater than, that of the Earth. Brouwer's view is that it is safer to give equal weight to all the pre-discovery observations and to refrain from rejecting any of them. This unexplained deviation in the motion of Uranus largely destroys the confidence in the solution of Pluto's mass from Neptune in which the latitudes of the planet contribute much of the weight, and for this reason it seems advisable to use only the longitudes of Uranus and Neptune.

Accuracy of the Numerical Integration Orbits. As a test of general interest the three area integrals and the energy integral have been evaluated for five dates and the differences from constancy do not reach the last printed decimal place. The available evidence indicates that, for intervals of four centuries for which the numerical integrations were carried out, these orbits are of a quality that would be extremely difficult to attain with general theories. A disadvantage of the numerical integration procedure is that the orbit is determined only for the period for which the integration has been carried out; but Stiefel has recently discussed a method by which a numerical integration could be related to the general planetary theory. Nevertheless, Brouwer is of the view that the numerical methods "should be looked upon as an aid for testing the results of analytical theories and for stimulating further theoretical developments".

Classical planetary theory in rectangular co-ordinates. A large portion of this section of Prof. Brouwer's lecture was devoted to an explanation of a method described by Dziobek in 1888 : an elliptic reference orbit is selected which nearly coincides with the orbital plane of the perturbed body so that the z co-ordinate is of the order of the perturbations. There is not space in this review to consider the method in detail, and it suffices to say that Davis and Clemence have found it superior to all other methods for perturbations of higher order than the second, and that van Woerkom and Brouwer are now using it in new theories for Uranus, Neptune and Pluto. Their introduction of certain additional methods has rendered it particularly suitable for automatic calculating machines, and the work has now the highest priority on the computing programme at Yale Observatory.

Generalized Planetary Theory. Although many attempts have been made to solve the planetary theory, there is still no satisfactory representation of planetary motions over long periods of time, and the only completed investigations of this type are solutions of the equations of secular variations. Though limited in scope, they may be suitable as a starting-point towards developing a general analytical theory. For reasons given in Prof. Brouwer's lecture, the choice at present is restricted to the Sun, Jupiter and Saturn, and to simplify the problem, inclinations are ignored. In the actual work the principal task is the development of the disturbing forces as the expansion of negative powers of the mutual distance, and this has been carried out by the staff of the Watson Scientific Laboratory. At the time of the delivery of the lecture, it was not known whether unforeseen difficulties would arise in the solution of the equations for the eccentricities and perihelia, but the indications at the time were favourable.

At the end of his lecture Prof. Brouwer said that much time has been devoted "to an unfinished project" in which team work is important. The work is a joint project of the United States Naval Observatory, the Watson Scientific Computing Laboratory and the Yale University Observatory, supported by the Office of Naval Research. The results obtained so far have been only made possible "by the magnificent support we have received and the unselfish co-operation of everyone concerned".

POPULATION OF BRITISH UNIVERSITIES IN THE 1960's

By Dr. WALLIS TAYLOR
University of Exeter

A REPORT appeared in *Nature* of January 21, p. 115, of the final session of the 1955 Conference of the Universities of Great Britain and Northern Ireland, when the topic discussed was "The Age-group Bulge and its Possible Effect on University Policy". At this Conference, two different estimates of the 'age-group bulge' in the United Kingdom were put forward. It would appear that both these estimates are too small. If this is so, and it is not quickly remedied, it may well result in a failure to make adequate provision for the universities in the next twenty years. I am not including here the increased demand for university education which is likely to come about because of the trend towards larger sixth forms in schools. This is a relevant issue; but at this stage I merely wish to urge a reconsideration of the estimates of the actual number of adolescents which we may expect to be alive in the years 1965 and later.

In the report cited, Dr. G. E. F. Chilver is quoted as saying that during the years 1964–67 we may expect "at least 7,500 more applicants for the universities each year; afterwards there will be a plateau, when the number of applicants will be at least 2,500 more than at present". Prof. R. G. D. Allen found these figures too small, forecasting that at the peak we may expect "more than 105,000, as compared with . . . 80,000 now", and in the plateau after the peak "at least 10–15 per cent higher than now, rising slowly and steadily during the late 1960's and 1970's as the trend towards more seventeen-year-olds at school operates".

While these estimates are in fair agreement about the peak, they diverge sharply in their consideration of the problem of the plateau. In terms of total university population in the United Kingdom (for this is the crucial issue) and if we regard the normal university course as one of three years, Dr. Chilver's estimates represent an increase of 28 per cent at the peak and 9 per cent afterwards in the plateau, whereas Prof. Allen's estimates represent 31 per cent increase at the peak and 10–15 per cent in the plateau. It is not clear from the report how much this discrepancy is due to the omission or addition of those students expected to arise from the trend to later school-leaving; but in any event I believe both estimates to be too small before we add on this extra load.

Since those children who will be the students aged 18, 19 and 20 in the years up to 1975 have already been born, our problem is merely to forecast their survival. The results of this exercise appear in Table 1.

If these figures are of the correct order, then we may expect a potential university population of, at the peak, 40 per cent greater than now, and over a period of eleven years (which includes the peak) a university population which varies between 18 and 40 per cent greater.

The calculations make allowance for the decreasing mortality which this population has experienced. We can check that this allowance is clearly not excessive so far as our present experience is concerned by reference to the Census of Population, 1951. The Census estimated the age-group 15–19

Table 1. Estimated Population of University Age, England and Wales, 1955–72

Year of birth	No. of births	Expected survivors at age 18	Total aged 18, 19, 20 in year stated		Proportion of 1955
1930	648,811	573,000			
1931	632,081	561,000			
1932	613,972	547,000	1,681,000	1950	102
1933	580,413	519,000	1,627,000	1951	99
1934	597,642	537,000	1,603,000	1952	98
1935	598,756	540,000	1,596,000	1953	97
1936	605,292	548,000	1,625,000	1954	99
1937	610,557	555,000	1,643,000	1955	100
1938	621,204	567,000	1,670,000	1956	102
1939	614,479	563,000	1,685,000	1957	103
1940	590,120	543,000	1,673,000	1958	102
1941	579,091	534,000	1,640,000	1959	100
1942	651,503	604,000	1,681,000	1960	102
1943	684,334	636,000	1,774,000	1961	108
1944	751,478	702,000	1,942,000	1962	118
1945	679,937	637,000	1,975,000	1963	120
1946	820,719	772,000	2,111,000	1964	128
1947	881,026	832,000	2,241,000	1965	136
1948	775,306	735,000	2,339,000	1966	142
1949	730,518	695,000	2,262,000	1967	138
1950	697,097	666,000	2,096,000	1968	128
1951	677,529	649,000	2,010,000	1969	122
1952	673,735	647,000	1,962,000	1970	119
1953	684,372	657,000	1,953,000	1971	119
1954	673,657	647,000	1,951,000	1972	119

inclusive to number 2,696,700 at the Census date. This is a very close approximation to the sum of the survivors to age 18 of those born in the years 1932–36 (Table 1). These latter number 2,691,000—a difference of 0·2 per cent. This rather circuitous argument is necessary because no detailed figures of the 15–19 age-group by single years of age are available for England and Wales. It does show, however, that the method is accurate so far as the present population is concerned.

The survival-rates for the later births have been calculated at progressively lower mortality-rates; but the lowest mortality-rates used are taken from the 1950–52 life-table[1]. This gives a conservative estimate of the survivors expected in the future and assumes that the mortality of those under the age of twenty will not fall from the present level. If mortality continues to decrease (as it has done during the past fifty years), we may expect a larger university population than these figures show. It is highly unlikely that anything will cause mortality-rates to be higher in the future than they were in the years 1950–52. The 1950–52 life-tables show that if the mortality-rates of these years continue for the next twenty years, we may expect 96 per cent females and 95 per cent males born in these years to survive to exact age twenty. Clearly mortality-rates cannot fall very much lower; but there is still a certain amount of room for improvement.

Estimates of future births can be, and have been, made to continue the series shown in the table. Briefly, they suggest that the numbers are unlikely to fall very much for some years. In so far as the number of births does fall, this is likely to be compensated in some degree by lower mortality of these later births.

For various reasons we may expect a higher proportion of 18-year olds to reach the required academic standard for entrance to the universities. These estimates, therefore, are likely to be minimal, since no allowance has been made for this factor.

If adequate provision is to be made for university expansion in the United Kingdom to allow the same proportion of each age-group to enter the universities, it is high time that we reached agreement about the expansion needed. I shall welcome, therefore, criticism of these estimates.

SUCCESSFUL SKIN HOMOGRAFTS IN INBRED CHICKENS

By A. G. COCK and MARGARET CLOUGH

School of Agriculture, Poultry Research Field Station, Boxworth, Cambridge

THE skin-homograft reaction, especially in mice[1], has proved to be a very sensitive indicator of slight genetic differences. There is a need for chickens of established antigenic uniformity, for example, in studies of 'immunological tolerance'[2], to which chickens are otherwise well suited. Previous attempts to obtain (without the aid of tolerance) persistent homografts of normal chicken tissues have made use of lines with quite low coefficients of inbreeding (F), and have met with complete failure[3], or only very slight success[4].

We have carried out skin-grafting tests on the I line of White Leghorn from the National Poultry Institute Northern Breeding Station, Reaseheath, Cheshire. Following an early history of irregular inbreeding in the United States, this line has been maintained since 1939 exclusively by full-sib matings[5]. The chicks used by us have an F of 98·75 per cent (slightly more than the equivalent of twenty generations of full-sibbing). Some use has also been made of two other inbred lines from Reaseheath: the C line (White Leghorn, F = 98·91 per cent) and the M line (Rhode Island Red, F = 78·5 per cent). The technique used in grafting was essentially that of Cannon and Longmire[6], with minor changes in the siting and orientation of the grafts. Homografts (approximately 1 cm. square) were exchanged between pairs of chicks, and each chick received in addition an autograft of its own skin. All grafts were made 13–14 days after hatching, this being safely beyond the age at which a foreign graft may sometimes survive by conferring tolerance on the host[2,6].

We have not succeeded, even with autografts, in obtaining a uniformly satisfactory 'take'. There has been conspicuous variation in the amount of tissue successfully healed-in (judged by the number of feathers) and some variation in the promptness with which feather-growth was initiated. A series of arbitrary grades has been used to express this variation in the 'vigour' of grafts: grade 3 for grafts which have been in every way unexceptionable; grade 2 for minor, and grade 1 for major deficiencies. Grade 0 covers grafts which disappeared at an early stage without having shown clear signs of an immunological reaction. Grade R is reserved for cases in which a typical and unmistakable homograft reaction was observed.

Three types of homograft have been used in testing the I line: (a) donor and host full sibs; (b) donor and host both pure I, but having the great-grandfather as latest common ancestor; (c) I donor on F_1 (C♂ × I♀ or $M \times I$) host, with the grandmother as latest common ancestor. A miscellaneous group, in which one or both parents of the donor are foreign to the host line(s), serves as control material. Table 1 shows the results according to grades.

The controls confirm earlier findings[2,6] that a rapid and violent homograft reaction normally occurs in

Table 1

	Grades (see text)					Total
	3	2	1	0	R	
(a) I on I (full sibs)	28	21	7	3	—	59
(b) I on I (non-sibs)	6	5	1	2	—	14
(c) I on $C \times I$ or $M \times I$	7	3	2	1	—	13
Total homografts testing I line	41	29	10	6	—	86
Autografts on same hosts	58	17	4	7	—	86
Miscellaneous controls (I on C, $C \times I$ on I, $C \times I$ on $M \times I$, etc.)	—	—	—	6	26	32
Autografts on same hosts	23	4	2	3	—	32

chicks of this age. In all but one of the twenty-six grade *R* cases destruction of the graft was complete by 9–12 days after grafting. (It is perhaps significant that in the remaining case, where the graft survived for about 20 days, the host was a very stunted individual.)

In contrast, only six of a total of eighty-six *I* line homografts have failed to survive, an incidence no higher than among the autografts on the same hosts. The remaining eighty have shown every sign of being permanent. All were inspected regularly for at least fifty days after grafting; all but nine were kept under observation for periods in excess of five months, and some, on hosts retained for breeding, are now of more than a year's standing. The only aspect of the results which suggests that the tissue antigens of the *I* line are not completely uniform is the lower proportion of homografts in grade 3, in comparison with the autografts. While the purely statistical significance of this difference is undoubted ($\chi^2_1 = 6\cdot65$, $P \simeq 0\cdot01$), it must be remembered that the 3–2–1 grading is necessarily somewhat subjective. If slight differences in tissue antigens exist within the *I* line, they merely make homografts more susceptible to unfavourable conditions of healing, without prejudicing the survival or well-being of tissue that has passed the healing-in stage. There is, moreover, no indication that homografts are less successful when donor and host are less closely related within the *I* line: the results of types (*a*), (*b*) and (*c*) are substantially identical. In this, and in the lack of any qualitative deficiencies peculiar to the homografts, the situation differs from that described by Billingham *et al.*[1] in certain inbred lines of mice yielding low-grade homograft reactions.

While it is thus open to question whether or not the *I* line is completely uniform in respect of tissue antigens, it at least approaches sufficiently close to uniformity for most experimental purposes. However, our colleague, Dr. D. G. Gilmour, informs us that recent agglutination tests show the *I* line to be segregating for at least one pair of alleles determining different red-blood-cell antigens, which suggests that the two types of antigen are genetically, as well as immunologically[2], quite distinct.

Owing partly to poor fertility and selective mating among the breeding stocks, results bearing on the uniformity of tissue antigens within the *C* and *M* lines are few in number and mostly indirect, being based on grafts exchanged between F_1 hybrids. They suggest, however, the tentative conclusion that the *C* line is considerably less uniform than the *I* line, whereas the *M* line (in spite of its much lower *F*) seems to be comparable in uniformity with the *I* line.

MICROSCOPICAL MEASUREMENTS OF OPTICAL PATH-DIFFERENCE BY MEANS OF COLOURED BIREFRINGENT INTERFERENCES AND A NEW COMPENSATION METHOD

By L. P. JOHANSSON

Institute of Optical Research, Stockholm 70

AND

B. M. AFZELIUS

Palynological Laboratory, Ranhammarsvägen 22, Bromma

THE optical path-difference given by the light when it passes through small objects in a microscope may be measured by means of a wave-shearing interferometer as originally proposed by Jamin[1] and using a Savart plate according to Françon[2].

The measuring device which we use is a Françon eyepiece in which the thickness of the Savart plate is chosen in order to give a sideways displacement between the two interfering wave-fronts somewhat larger than the enlarged image of the object detail to be measured. The eyepiece is combined with a measuring device designed by one of us (L. P. J.) with a reference area incorporated into the field of view.

Fig. 1 shows the optical components in the microscope. The white light from a thin slit goes as a parallel beam through the object. Any good normal objective may be used. After the lens L_3 the light goes as a parallel beam through the Savart plate, placed between two crossed 'Polaroids' P_1 and P_2. The device for measuring the optical path-difference is placed at image 1. This device consists of a rotatable glass wedge and is thus isotropic, which is a great advantage over birefringent compensators. Lens L_4 gives at image 2 a new image of the object and an image of the wedge. Fig. 3 shows the field of view, where a double image of the object is seen. In Fig. 2 the same object is photographed in an ordinary microscope.

Different optical path-differences in the two images give rise to different interference colours on the Newtonian scale equally distant on both sides of the coherent background colour. By turning the wedge the light passes through the Savart plate at different angles, and the colour will be changed. A hole in the middle of the wedge through which the undistorted background appears serves as a reference. To measure the optical path-difference of part *a* in Fig. 3 the colour of a_1 is made equal to the reference colour by turning the wedge a certain angle β from the zero point. If also the second image is free, or by rotation of the microscope table can be made free, from other parts of the object, as in a_2, etc., its colour is compensated by turning the wedge in the

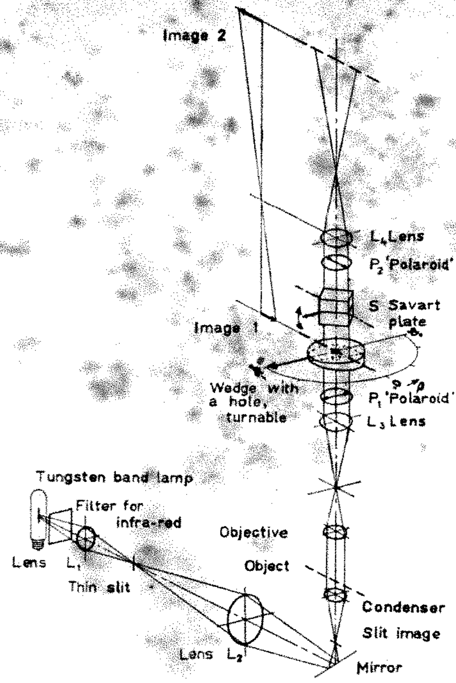

Fig. 1.

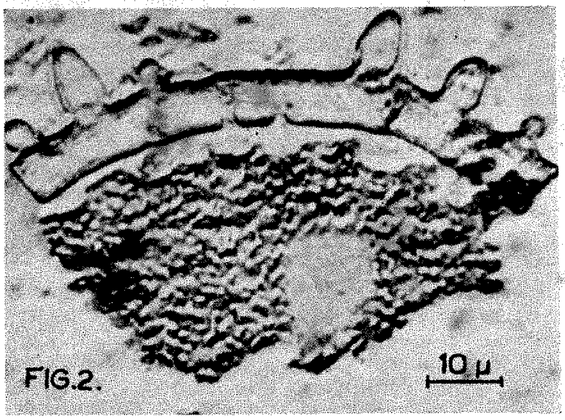

Fig. 2. Section through part of osmium-fixed pollen grain of *Althaea rosea*. Geometrical thickness of the section, 4800 A.

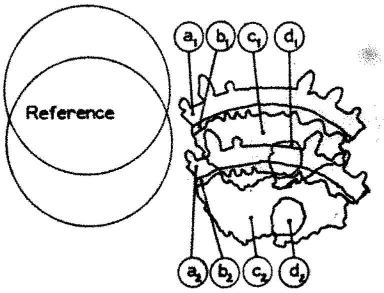

Fig. 3

opposite direction. The angle between the two settings is then 2β. We then obtain: optical path-difference = constant × sin β.

The constant depends on the glass wedge and the Savart plate used. The range of measurement can be altered by choosing different wedges. In order to obtain the highest possible accuracy, the colours of the field of view should be even. That means that the light is parallel through the Savart plate. The Savart plate also has to be adjusted to give the background, 'the sensitive colour' (purple-violet) of the first order[3]. Under ideal conditions, an accuracy (maximum error) of about ± 10 A. in optical path-difference can be obtained. Ideal conditions mean a relatively large detail of the object for comparison; the detail ought also to be uniform. If the object is not regular, the accuracy will, of course, not be so high. The method has been tried for measuring the optical path-difference of various objects; for example, thin films of evaporated zinc sulphide, small grooves etched in glass (these may be used as a standard object), silver bromide crystals in photographic emulsions and blood corpuscles. It is also possible to use the same compensation method for measuring the optical path-difference by reflexion microscopy; for example, for studying metallographic surfaces.

More complete descriptions of apparatus and measurements will be published elsewhere. The apparatus is being manufactured and will be put on the market by Jungnerbolaget, Stockholm 14.

As an example of the uses of this instrument, we give some measurements of the optical path-differences of different cell components in thin sections of pollen grains and spores measured in air and water, respectively. The sections were made on a Spencer microtome modified for thin sectioning at the Palynological Laboratory in Bromma, Sweden. No measurable anisotropy was found in these objects.

The pollen wall consists principally of two layers, exine (*a*) and intine (*b*). The difference in optical path-difference between the exine and the intine is clearly shown in Table 1 and is tolerably constant. In a well-fixed grain the cytoplasm (*c*) comes out in various colours. The optical path-differences of the cytoplasm given in the table are mean values obtained by integration over the whole area. On account of the heterogeneity of the cytoplasm, it is, of course, of less value to give a mean value of its optical path-difference, and it might be possible to measure different cytoplasm components.

Some measurements from part of a nucleus (*d*) are given. This part of the nucleus gives a greater optical path-difference than the exine. It must be borne in mind, however, that the exine does not stain with osmium tetroxide[4], whereas the nucleus does.

GROWTH OF SUCROSE CRYSTALS

By H. E. C. POWERS

Tate and Lyle, Ltd., Thames Refinery, London, E.16

THE manner of growth of cane or beet sugar crystals resembles in many ways that observed on crystals of many salts by Bunn and Emmett[1], and first reported at the Faraday Society Discussion on Crystal Growth at Bristol in 1949. These authors observed, in the light microscope, layers 1000 A. or more in thickness spreading over the faces of growing crystals of many salts and a few organic substances containing strongly polar groups, but did not see them on sucrose crystals. I have found, however, that on sucrose crystals growing on a microscope slide at room temperature in syrup of 1·05–1·3 supersaturation, layers can be seen spreading over the various faces (Figs. 3,4). Perhaps those on 100, 101 and 001 are the most perfect, while the 'end' faces 110, etc., sometimes suggest rather an 'end grain' effect, which with any encouragement develops into a castellated type of multi-crystal development. In some cases the layers may be seen to spread outwards from some origin in the mid-section of the face, and other phenomena seen by Bunn and Emmett which are also exhibited by sucrose crystals are the 'wrapping over' of a layer on to a neighbouring face, and the formations of pits by layer encirclement. No definite signs of growth by the screw dislocation mechanism have yet been seen.

To facilitate the recognition of the faces to which references have been made, two diagrams (Figs. 1 and 2) have been reproduced, the one the simplest or most perfect sucrose crystal, the other a more complex form which illustrates faces which may develop under different conditions of growth.

Electron micrographs of a cleavage face parallel to 100, at a magnification of 20,000, show a stepped structure, perhaps related to layer growth (Fig. 6). Some micrographs show a kind of mosaic structure; the first such micrograph was shown to me by Dr. van Hook, who used an alcohol etched surface, and a similar mosaic structure was also shown by some more of the micrographs kindly prepared for me by the Associated Electrical Industries Research Laboratories, using the above internal cleavage face (Fig. 5). Further work is necessary and is in progress; but it seems to me that these results do indeed indicate probable internal structure, particularly since X-ray photographs by the above Laboratories also showed diffuse reflexions which could indicate crystallite formation or extensive imperfections.

A phenomenon of considerable technological importance which depends upon the mechanism of crystal growth is the presence of water inside the crystals. Vapour pressure measurements before and after crushing prove the presence of relatively pure sucrose solution inside the crystals as distinct from the thin layer of relatively exhausted low-purity syrup remaining on the surface of 'dry' sucrose crystals. The proportion of water present increases rapidly with the size of crystal, normal granulated sugar crystals of about 0·5 mm. length having only 0·01 per cent, while crystals of 25 mm. length may have as much as 0·4 per cent. Some of this water is present in cavities large enough to be seen in the light microscope (Fig. 7), which would be seen more frequently in large than in small crystals, but the possibility that some of it is trapped between layers or in mosaic cracks cannot be overlooked. There is an intriguing problem awaiting solution as to the

mechanism of the layer growths enclosing these liquor intrusions.

When sucrose crystals are grown in static agar gel (to damp down free syrup movement), growth does not occur by the spreading of the layers right across the faces; there is a striking surface development I have termed 'tesselated' (Fig. 8). There is a large number of independent growth centres on each face, each bounded by what appears to be 101, $10\bar{1}$, etc., facets. Prof. Tolansky is examining the interfacial angles of these tesselations to see if they do indeed correspond to the normal side faces. Other gelling agents produce similar effects, which, therefore, are probably not due to a surface adsorption effect, but to an interference with that movement of solution which may play so vital a part in normal layer growth.

A study of nucleation of sucrose has also provided certain features which may be of interest. A single large crystal was attached to an axis which was then rotated at varying speeds in a nuclei-free solution of known supersaturation. The resulting solutions were cooled to assist nuclei to grow. Counts were then made of nuclei produced under different conditions. At sufficiently high speed, nucleation appears to be produced virtually in a saturated solution. At the suggestion of Dr. C. W. Bunn, a 'Perspex' model was then used in place of the sucrose crystal. Nucleation was effected under these conditions at a speed of several hundred revolutions per minute and 1·2 supersaturation. It appears to me that a plausible theory to account for this latter phenomenon is that the violent movement produces a periodic node and antinode distribution in the normally uniform distribution of sucrose and water molecules in solution, thus increasing the statistical chances of true nuclei being formed by the excessive local supersaturation. I find that a similar theory was put forward by the Earl of Berkeley, but this does not appear to be widely known.

It also appears a tenable hypothesis that the nuclei produced by shedding from a pre-existing crystal are larger initially than those produced in absence of any pre-existing crystal and that this accounts for the difference in the borderline supersaturation. Further, there is some slight evidence that in concentrated sugar solutions there may exist formless aggregates of molecules which have not yet attained regular crystal lattice formation.

I wish to attract the attention and collaboration of others carrying out similar researches upon substances other than sucrose, since it is becoming increasingly evident that allied phenomena are being discovered in the crystallization of substances so dissimilar as inorganic salts, metals (from melts) and non-polar organic substances such as sucrose. Prof. J. Bernal, at a recent conference in Oxford, directed attention to the desirability of more intensive study of non-polar molecular crystals.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Immunity of Lysogenic Bacteria

BACTERIAL virus (phage), in its symbiotic phase (prophage), renders the host bacterium lysogenic, and confers on it immunity against lysis by free phage particles of the homologous type, whether temperate or virulent in character. Hyper-virulent mutants, which are rare, may be exceptions to this rule.

Earlier work suggested that this immunity might cover not only homologous phage but also phages of related types. An extensive survey of the *A* phages of *Salmonella typhi-murium* (which form a closely related group) shows that this conception needs revision. Some cross-immunity does exist, but it is far from being universal or complete. Four different reactions have been found.

(1) Reciprocal cross-immunity may be absolute, so that lysogenic bacteria carrying prophage *L* and lysogenic bacteria carrying prophage *M* (the letters used are symbols only, and do not refer to named phages) are equally resistant to temperate particles of phages *L* and *M*. Neither lysis, nor any change in lysogenesis, occurs, although the free particles may be well adsorbed.

(2) There may be reciprocal sensitivity. Thus, when lysogenic bacteria carrying prophage *L* are exposed to temperate particles of phage *N* or, vice versa, when lysogenic bacteria carrying prophage *N* are exposed to temperate particles of phage *L*, some bacteria may be lysed while others may become doubly lysogenic, and carry both prophages *L* and *M*.

(3) One phage may be partly dominant over the other. In this case, when lysogenic bacteria carrying prophage *L* are exposed to temperate particles of phage *O*, they show complete resistance; but when bacteria carrying prophage *O* are exposed to temperate phage particles of phage *L*, some bacteria are lysed and others survive, showing double infection with prophages *L* and *O*.

(4) One phage may be completely dominant over the other. Thus when lysogenic bacteria carrying prophage *L* are exposed to temperate particles of phage *P*, they show complete resistance: but when lysogenic bacteria carrying prophage *P* are exposed to temperate particles of phage *L*, some are lysed, while in others phage *L* evicts and replaces prophage *P*, so that the surviving bacteria carry only prophage *L*. Sometimes, however, a few of the surviving bacteria are phage-free; the strong phage has apparently turned out the weak, but has failed to take its place, so that the bacterium has been 'cured'.

Certain of the 'cured' bacteria recovered in this way are very efficient indicators. The first to be encountered, strain *Q*1, supports the growth of all the identified phages of *S. typhi-murium.* Hitherto it has been necessary to use two different indicator strains (for some time suspected to contain weak symbiotic phage) to isolate the complete series; this has made exact comparisons of the phages difficult. It is an easy matter to prepare pure suspensions of these temperate phages, and with them to produce lysogenic strains of *Q*1 which are alike except for their prophage content. These lysogenic strains have a specific immunity which provides a delicate means of identifying phages. A test, based on this principle, has revealed differences which were hitherto unsuspected, and has greatly enhanced the accuracy of the method of 'typing' bacteria by determining the prophages they carry.

In the course of these experiments no 'hybrid' phages have been found; but a much larger number of colonies would need to be examined before the possibility of their occurrence could be definitely excluded. Certain of the free phage preparations contain a non-particulate lytic principle which acts on some strains of lysogenic bacteria and not on others. This also has still to be investigated.

Role of Non-Protein Nitrogen in the Synthesis of Hæmoglobin in the Reticulocyte *in vitro*

A CONSIDERABLE increase of non-protein nitrogen takes place when washed suspensions of red cells of anæmic rabbits, which are rich in reticulocytes, are incubated in physiological saline. This does not occur in suspensions from animals which are low in reticulocytes (see Table 1). The relation between increase of non-protein nitrogen and respiration, which is indicated by the data, is further borne out by the observations that: (*a*) increase of non-protein nitrogen is lower under anaerobic conditions (Table 2); (*b*) that it is inhibited by 2,4 dinitrophenol (Table 3).

Table 1

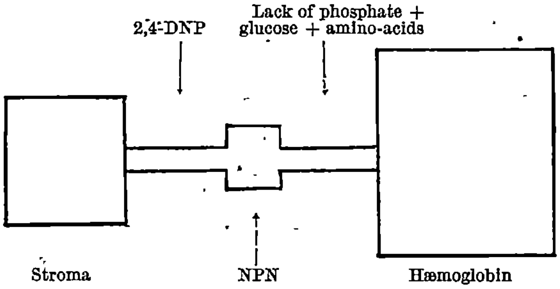

Fig. 1. Scheme of hæmoglobin formation with inhibitory effects

In the presence of phosphate, glucose and eleven essential amino-acids, non-protein nitrogen increases only minimally (Table 4); on the other hand, new formation of hæmoglobin is observed. No increase of hæmoglobin takes place in saline alone.

The stroma is the source of both non-protein nitrogen and newly formed hæmoglobin[1]. Thus the formation of hæmoglobin may be considered as a process of transformation of one protein (stroma) to another with an intermediate non-protein nitrogen phase. Fig. 1 shows a scheme which summarizes the observed effects. It indicates that lack of phosphate, glucose and amino-acids blocks the synthesis of hæmoglobin from non-protein nitrogen, while addition of 2,4-dinitrophenol inhibits breakdown of stroma.

Two points may be made: (1) The same conditions are necessary for hæmoglobin synthesis that have proved optimal for the breakdown of the substantia reticulo filamentosa, which is a specific ribonucleic acid[2]. A relation between *breakdown* of ribonucleic acid and synthesis of protein is suggested. (2) The effect of 2,4-dinitrophenol suggests a connexion between breakdown of protein, that is, non-protein nitrogen accumulation, and oxidative phosphorylation. A similar relation is assumed for the breakdown of ribonucleic acid[3].

Recovery from Irradiation following the Administration of Cultured Tissues

CBA mice which have been given a lethal dose of X-rays recover if treated with intravenous injections of spleen cells from infant mice. Barnes and Loutit[1] have shown that this therapeutic activity can be preserved by storing fragments of such spleen with glycerol at − 79° C.

Storage of whole spleens *in vivo* in the peritoneal cavity of mice does not preserve the activity.

Tissue culture of fragments of infant spleen and of embryo liver preserves activity for some days. These tissues were cultured in a basic medium of rabbit serum and glucose, using Trowell's culture-cup technique[2] and, more recently, a modification of Chen's lens-paper technique[3]. The latter gave better mechanical recovery of explants.

Injected material	30-day survival	Per cent survival
1. Cultures (*CBA* mice)		
Infant spleen, rabbit serum/glucose, 48-hr. culture	11/15	73·3
As above, 'wandering cells'	0/5	0
Embryonic liver, rabbit serum/glucose		
48-hr. culture	56/93	60 2
72-hr. culture	3/5	60
96-hr. culture	3/5	60
As above, 'wandering cells'		
48-hr. culture	0/5	0
72-hr. culture	5/15	33·3
5-day culture	0/5	0
Embryonic liver, synthetic medium, 48-hr. culture	1/10	10
Embryonic liver, heat-inactivated rabbit serum/glucose, 48-hr. culture	0/10	0
2. Controls		
Fresh rabbit serum	1/105	0·95
Rabbit serum/saline	0/5	0
Saline	0/30	0
Culture medium	0/35	0

Results are given in Table 1. The cultured embryonic liver is active for as long as four days of culture, although two days has been taken as a standard culture time. Cells which drop out or wander from the explant into the culture medium are variably active, depending upon the duration of culture.

Cultures in synthetic medium[4] or fresh rabbit serum-glucose which has been inactivated at 56° C. for half an hour are not active. Their gross and histological appearance is excellent, however.

Controls usually die by the fourteenth day following irradiation and injection. In treated mice, the survivors live for many months.

Active cells are known to be hæmatopoietic in nature[5,6] and preliminary experiments indicate that the failure of heat-inactivated and synthetic media to produce active cells may be due to a deficiency of a principle for stimulation of hæmatopoiesis.

I wish to thank Dr. D. W. H. Barnes and Dr. J. F. Loutit for advice and assistance in this work.

Metabolism of Glycerol, Sorbitol and Related Compounds by Spermatozoa

The finding that the addition of glycerol to semen increases considerably the proportion of spermatozoa which survive freezing and storing at − 79° C.[1,2] opened up the question as to whether or not glycerol can be metabolized by the intact sperm cells. Early experiments indicated that, unlike certain glycolysable sugars and organic acids, glycerol, in common with other alcohols, has no marked initial-rate preserving effect on the sperm respiration[3], and exerts its action mainly through a protective influence on sperm colloids, probably owing to its high electrolyte- and water-binding capacity[4,5]. More recent investigations, however, have shown that although glycerol does not affect sperm motility and respiration in a diluent containing fructose, it increases markedly the oxygen consumption of washed sperm suspensions, giving rise at the same time to significant quantities of lactic acid[6]. It has also been demonstrated that glycerol labelled with radioactive ^{14}carbon enters spermatozoa in measurable amounts; sperm cells separated from the seminal plasma showed a higher uptake and utilization of glycerol than did spermatozoa in the presence of seminal plasma[7]. The present study was undertaken to investigate: (1) the relationship between glycerol disappearance and lactic acid formation; (2) the behaviour of compounds related to glycerol such as dihydroxyacetone and phosphoglycerol. Glycerol was determined colorimetrically[8], and the other methods used were those described earlier[9].

The results, which are based on experiments with ram spermatozoa, are briefly as follows.

(1) Glycerol (0·01 *M*) is utilized aerobically by suspensions of washed spermatozoa (3×10^8 cells/ml.) at a rate of about 1 mgm./10^9 sperm/hr. at 37° C. The disappearance of glycerol is accompanied by an increase in the oxygen uptake, of the order of 0·1–0·3 ml. O_2/10^9 sperm/hr., and by the accumulation of lactic acid, which appears to be an intermediary product in the oxidative breakdown of glycerol.

(2) The extent to which lactic acid accumulates depends on the concentration of phosphate used for the preparation of the sperm suspensions. It is about 0·4 mgm. lactic acid/10^9 sperm/hr. in the presence of phosphate buffer *p*H 7 (0·08 *M*) as compared with 0–0·1 mgm./10^9 sperm/hr. in the absence of phosphate. A higher rate of lactic acid accumulation in the presence of phosphate coincides with a lower oxygen uptake; this is due to a depressing effect of phosphate on the oxidation of lactic acid by spermatozoa.

(3) The breakdown of glycerol is a function of live spermatozoa and can be abolished either by heating or by the addition of spermicidal agents, for example, cetyltrimethylammonium bromide. It is not affected by the addition of penicillin. There is little or no disappearance of glycerol under anaerobic conditions. Glycerol has no appreciable effect on the rate of anaerobic fructolysis in sperm suspensions to which fructose has been added; but it exerts a 'sparing effect' on the aerobic fructolysis.

(4) In the normal course of glycerol oxidation, both in the presence as well as in the absence of phosphate, there is little or no accumulation of bisulphite-binding substances. However, such substances, mostly alkali-stable, can be shown to accumulate in the presence of sodium fluoride (0·02 *M*), particularly when glycerol is used in a high concentration (0·1 *M*). Moreover, when glycerol is replaced by dihydroxyacetone (0·01 *M*), the oxygen uptake of spermatozoa is increased and lactic acid is formed in about the same amounts as from glycerol. Phosphoglycerol (both α- and β-) is dephosphorylated by washed ram spermatozoa anaerobically as well as aerobically. Whereas, however, anaerobically glycerol accumulates as the final product of the enzymic dephosphorylation of phosphoglycerol, aerobically it is oxidized further, thus increasing the oxygen consumption of spermatozoa. Unlike phosphoglycerol, glycerylphosphorylcholine has no effect on sperm respiration.

(5) Apart from glycerol, a number of other alcohols have been tested as well as inositol, mannitol, dulcitol, erythritol and sorbitol. Sorbitol was the only one which produced a marked increase in the oxygen uptake of washed spermatozoa. The oxidation of sorbitol (0·01–0·1 *M*) was accompanied by the formation of lactic acid and a yeast-fermentable ketosugar which was identified as fructose. The ketose appears in considerable amounts when a high concentration of sorbitol (0·1 *M*) is used or else when the sperm suspension contains a low concentration of sorbitol (0·01 *M*) together with an equally low concentration of glycerol.

This investigation was carried out on behalf of the Agricultural Research Council; one of us (I. G. W.) is indebted to the Australian Council for Scientific and Industrial Research for a fellowship.

Metabolism of Lysergic Acid Diethylamide

Although the hallucinogenic agent, lysergic acid diethylamide, has been the subject of numerous investigations, little is known about its biological fate. The development of a specific and sensitive method for the estimation of lysergic acid diethylamide in biological materials has enabled us to study its physiological disposition and metabolism.

Lysergic acid diethylamide was extracted from a salt-saturated alkaline solution of biological material into heptane containing 2 per cent *iso*amyl alcohol. The compound was returned to dilute hydrochloric acid and the fluorescence measured in a Farrand or Bowman spectrophotometer[1] at 445 mμ after activation at 325 mμ. As little as 0·001 μgm. of lysergic acid diethylamide could be determined by this method. Concentrations of the drug greater than 5 μgm. per ml. may be measured spectrophotometrically at 310 mμ.

After the administration of lysergic acid diethylamide to a cat, the drug was found in all tissues in the following order of decreasing concentrations: bile, plasma, lung, liver, kidney, brain, cerebrospinal fluid, spleen, intestine, muscle and fat. From tissue distribution studies, it was calculated that lysergic acid diethylamide exerted its psychological effects in man at a concentration of 0·0003 μgm. per gram of brain tissue.

Lysergic acid diethylamide was almost completely transformed when administered to the intact animal,

Table 1. THE ENZYMIC TRANSFORMATION OF LYSERGIC ACID DIETHYLAMIDE

Additions	LSD metabolized (μmole)
Microsomes + soluble fraction	0·53
Soluble fraction	0·00
Microsomes	0·04
Microsomes + 35 μmoles of glucose-6-PO_4	0·04
Microsomes + 35 μmoles of glucose-6-PO_4 + 1 mgm. of glucose-6-PO_4 dehydrogenase*	0·48

The microsomes and soluble fraction were prepared by fractional centrifugation of a homogenate of 200 mgm. of guinea pig liver in five volumes of isotonic potassium chloride. The reaction mixtures contained 500 μmoles of potassium phosphate buffer (*p*H 7·9), 25 μmoles of magnesium chloride, 1 μmole of triphosphopyridine nucleotide, 25 μmoles of nicotinamide, 0·66 μmole of lysergic acid diethylamide, and water to make a final volume of 5·0 ml. Incubation time 120 minutes at 36° in an atmosphere of 95 per cent oxygen and 5 per cent carbon dioxide.

* 2·4 Kornberg units per mgm. of protein (ref. 2).

only traces being excreted in the urine or faeces. Considerable species differences in the rate of metabolism of lysergic acid diethylamide were found. When tissue slice preparations were used, it was observed that only the liver was capable of metabolizing the compound. Further studies at a subcellular level indicated that the transformation of lysergic acid diethylamide was catalysed by enzyme systems present in mammalian liver microsomes when supplemented with oxygen and a reduced triphosphopyridine nucleotide generating system (Table 1). Microsomal enzyme systems requiring triphosphopyridine nucleotide and oxygen have previously been found to catalyse many metabolic reactions[3].

Lysergic acid and *nor*lysergic acid diethylamide, possible metabolic products of lysergic acid diethylamide, were not found after incubation of lysergic acid diethylamide with guinea pig liver microsomal preparations. After extracting the residual lysergic acid diethylamide from the reaction mixture, a butanol-soluble metabolite was found which gave a positive Folin–Ciocalteu reaction[4]. Unlike lysergic acid diethylamide, the metabolite gave no reaction with Hopkins-Cole or Van Urk's dimethylaminobenzaldehyde reagents[5]. These observations suggested that substitution had occurred on position 2 of the indole ring. Since alkaline hydrolysis is known to cleave oxindoles at the amide linkage with the formation of the salt of an amino-acid containing a diazotizable aromatic amino group[6], the lysergic acid diethylamide metabolite was heated at 100° in 2 *N* sodium hydroxide for five minutes and afterwards treated with nitrous acid in acid solution. An intense wine colour appeared when the diazotization mixture was added to an alkaline solution of β-naphthol. These observations indicated that lysergic acid diethylamide was converted to 2-oxy-lysergic acid diethylamide by the microsomal enzyme system dependent on triphosphopyridine nucleotide. Preliminary studies have shown that ergotamine may undergo a similar transformation.

Previous studies have shown that lysergic acid diethylamide blocks synaptic transmission in the lateral geniculate nucleus[7]. An intracarotid administration of 0·4 mgm./kgm. of 2-oxy-lysergic acid diethylamide in nembutalized cats did not alter the postsynaptic response to optic nerve shock, whereas 0·03 mgm./kgm. lysergic acid diethylamide resulted in an 80 per cent decrease in the amplitude of the postsynaptic response. 2-Oxy-lysergic acid diethylamide was also found to be without effect on the spontaneous cortical activity recorded during barbiturate anæsthesia. The oral administration of 300 µgm. of 2-oxy-lysergic acid diethylamide did not produce any psychological effects in human subjects who responded to 30 µgm of lysergic acid diethylamide. It may be concluded on the basis of this evidence that 2-oxy-lysergic acid diethylamide does not show activity like lysergic acid diethylamide in the central nervous system.

Since other investigators have shown biological interactions between lysergic acid diethylamide, serotonin and tranquillizing agents[8], the effect of serotonin, chlorpromazine and reserpine on the metabolism of lysergic acid diethylamide by the microsomal preparation was examined. It was found that chlorpromazine (1×10^{-4} *M*), serotonin (1×10^{-3} *M*) and reserpine (1×10^{-3} *M*) inhibited the enzymatic oxidation of lysergic acid diethylamide 70 per cent, 40 per cent, and 20 per cent, respectively.

A detailed report of these investigations will be published elsewhere.

Soil as a Habitat of Vitamin-requiring Bacteria

MOST of the B vitamins have been shown to occur in arable soil, their presence being attributable to release from vitamin-containing plant and animal residues, liberation from the roots of growing plants and synthesis by micro-organisms. It is therefore not surprising that bacteria are present for which certain vitamins are essential for growth. It has been previously shown[1,2] that among the indigenous soil bacteria are forms requiring one or more preformed vitamins, while other reports[3,4] have pointed to the need of other types for certain specific factors, namely vitamin B_{12} and the terregens factor. However, apart from a recent report[5] on the incidence of bacteria requiring vitamin B_{12} and the terregens factor in soil and in the rhizosphere of certain plants, no information is available concerning the abundance in soil of bacteria requiring specific vitamins for growth.

A study has been made of the indigenous bacteria of a field soil for which vitamins of the B group were needed for growth, the experiments having been arranged to permit an estimation of the numbers of those requiring specific vitamins. This involved the use of non-selective plating and isolation procedures and determinations of the individual needs of the isolated cultures for the following vitamins by employing suitable vitamin-free basal media: thiamine, biotin, riboflavin, pantothenic acid, nicotinic acid, *p*-aminobenzoic acid, folic acid, vitamin B_{12}, pyridoxin (with pyridoxal and pyridoxamine), choline and inositol.

Table 1

Vitamin required (either alone or with others)	Vitamin-requiring bacteria		
	No of isolates	Percentage of total isolates	Approximate number per gm. soil
Thiamine (B_1)	96	19·2	10,100,000
Biotin	81	16·2	8,500,000
Vitamin B_{12}	35	7·0	3,700,000
Pantothenic acid	23	4·6	2,400,000
Folic acid	15	3·0	1,600,000
Nicotinic acid	10	2·0	1,000,000
Riboflavin	3	0·6	300,000

Of a total of 499 isolates, 135 or 27·1 per cent (corresponding to 14·1 millions per gm. of soil) required one or more vitamins for growth. The vitamins found to be needed, either alone or with others, are shown in Table 1 in order of frequency. With the great majority of the strains more than one vitamin was required; only in the case of thiamine, biotin and riboflavin were organisms found that needed but a single vitamin. In all, seventeen different 'patterns' were noted for vitamin requirements. For none of the isolates was pyridoxin, *p*-aminobenzoic acid, choline or inositol found to be essential, though in some cases these factors provided stimulation of growth.

Microbial growth-promoting substances and organisms requiring or synthesizing them have received less attention than the subject of microbial antagonisms in soil; yet growth-factor effects could well be as important as antibiotic activity in affecting the microbial equilibrium. The findings reported underline the importance of including growth-promoting substances in any consideration of the microbial economy of soils, whether related to problems of fertility or to those of the interrelationships of the normal soil microflora, plant disease organisms and the plant itself. The results also emphasize the wide diversity of the soil microflora in its nutritional aspects and point to the soil as an important habitat of vitamin-requiring bacteria.

Action of Pepsin on Synthetic Substrates

It has recently been suggested[1] that the apparent first-order kinetics observed in the hydrolysis of certain synthetic substrates (for example, acetyl-L-phenylalanyl-L-tyrosine) by pepsin could be explained if one of the hydrolysis products (acetyl-L-phenylalanine) were only slowly released from the enzyme, as indicated in the following scheme:

$$\begin{array}{ccccccc} E & + & AB & \underset{k_2}{\overset{k_1}{\rightleftharpoons}} & E.AB & \xrightarrow{k_3} & EA + B \\ e & & s & & p & & q \\ \text{(total)} & & & & & & \end{array}$$

$$EA \xrightarrow{k_4} E + A$$

where $k_4 < k_3$. (A, acetyl-L-phenylalanine; B, L-tyrosine. The small letters will be used as symbols for the concentrations of the various species, in the equations which follow.) The reaction-rate was measured by the rate of production of B (L-tyrosine amino nitrogen). This scheme would not, however, explain the observed results.

Making the usual steady-state assumptions and putting $K_m = \dfrac{k_2 + k_3}{k_1}$ we have:

$$\frac{ds}{dt} = k_3 p = \frac{k_3(e - q)s}{K_m + s}$$

This equation cannot be integrated directly (contrast ref. 1, equation 22) since q is a function of t. However, in the steady state $k_3 p = k_4 q$. That is, dq/dt, like dp/dt, is so much smaller than ds/dt that it can be neglected except in the initial stages of the reaction.

$$\text{Therefore,}\quad q = \frac{k_3 es}{K_m k_4 + (k_3 + k_4)s}$$

$$\text{and}\quad p = \frac{k_4 es}{K_m k_4 + (k_3 + k_4)s} = \frac{es}{K_m + \left(1 + \dfrac{k_3}{k_4}\right)s}$$

When $k_3 > k_4$, first-order kinetics will only be observed when $s \ll K_m$. This mechanism cannot explain the observed results, since s was of the same order of magnitude as K_m. It is clear, from the equation for p, that the proposed mechanism will lead to Michaelis–Menten kinetics with apparent k_3 and K_m values that are $k_4/(k_3 + k_4)$ times their true values.

The succeeding communication describes further experiments which provide the correct explanation of the first-order kinetics.

N. M. GREEN

Department of Biochemistry,
University, Sheffield 10.

[1] Baker, L. E., *J. Biol. Chem.*, 211, 701 (1954).

IN a previous communication[1] regarding the action of pepsin on two of its synthetic substrates, acetyl-L-phenylalanyl-L-tyrosine and N-acetyl-L-tyrosyl-L-tyrosine, results were obtained which seemed to indicate that the products of the hydrolysis were released from the enzyme-substrate complex at different rates, and that it was this phenomenon which accounted for the logarithmic course of the reaction. A communication afterwards received from Dr. N. M. Green showed that the release of the second product at a very slow rate, according to the hypothesis presented, would not lead to a logarithmic course (see accompanying communication by Dr. N. M. Green). A further study of the hydrolysis of acetyl-L-phenylalanyl-L-tyrosine by pepsin was therefore made, and has shown the conclusions that were previously drawn to be incorrect.

Since Haldane[2] has shown that a hydrolysis will follow a logarithmic course when the affinity of one of the products for the enzyme is the same as that of the substrate, experiments on the inhibiting effects of the products were again made. In these experiments it was found that concentrations of acetyl-L-phenylalanine and of the combined products of the hydrolysis which had previously inhibited the hydrolysis of acetyl-L-phenylalanyl-L-tyrosine only 6 per cent now caused 22 per cent inhibition. A search for any differences in technique that might account for these divergent results revealed that in the experiments previously reported the pepsin that had been used for forming the products had remained with those products until the experiment on their inhibiting effect was made (about 24 hr. later); while in the present experiments the pepsin that had been used for forming the products was heat-killed as soon as they were formed. Also, in the experiments previously made, the acetyl-L-phenylalanine had been mixed with the pepsin on the day before the experiment, just for convenience, and stood in the ice box at pH 2·0 until the experiment was made. Tests designed to ascertain if this standing with the pepsin was the cause of the low inhibition that was observed revealed that the combined products of a hydrolysis which caused 21 per cent inhibition if they were used immediately after being formed would produce only 9 per cent inhibition after they had stood overnight at room temperature with pepsin; and acetyl-L-phenylalanine, that caused 22 per cent inhibition before standing with pepsin, caused only 10·3 per cent inhibition after standing overnight at pH 2·0 in the ice box.

It is evident from the above that the inhibiting effect of acetyl-L-phenylalanine is much greater than previous results had indicated. To ascertain if its affinity for pepsin was the same as that of the substrate, the velocity constants that would be obtained, if this were so, were calculated from the Haldane equation[2] for a number of different concentrations of this product and the substrate. These were found to agree closely with those obtained experimentally for the same conditions. The logarithmic course of these reactions may therefore be attributed to the fact that the affinity of one of the products for the pepsin is the same as that of the substrate; and not, as was previously supposed, to a difference in the rate at which the two products are released from the enzyme-substrate complex.

Growth of Mouse Tumour in the Chick Embryo with Retention of Capacity by the Chick to form Antibody to the Tumour Cells in Later Life

THE development of tolerance to foreign antigens following introduction of these antigens during embryonic life does not necessarily mean that exposure of the embryo *per se* is a sufficient condition for the production of the tolerant state. It appears that the most impressive tolerance has followed the introduction of living homologous cells[1–4], while other types of antigens produce no tolerance or only partial tolerance[5,6]. The possibility exists that the greater effectiveness of the living cells is derived not from their interaction with the embryo alone, but from their persistence in the growing animal over a more prolonged period. If an experimental method existed by which transferred homologous cells could, after a time, be destroyed and the antigens eliminated, this hypothesis could be tested. The following experiment dealing with an analogous situation for heterologous cells is consistent with such a hypothesis.

The Krebs-2 ascites tumour, a highly malignant, uniformly fatal tumour of mice, can be grown in the chick embryo. When we injected a suspension of these cells intravenously into 11-day chick embryos, the tumour cells invaded the chick organs and could regularly be found growing in the embryonic liver, brain or heart in the form of separate islands, each presumably arising from a single injected cell. On about the seventeenth day of incubation, the tumour cells began to degenerate and the tumour areas became infiltrated with eosinophilic cells. By the time of hatching (twenty-first day) the tumour was generally eliminated and the birds could be raised to maturity in a tumour-free state. (The reason for the general failure of the tumour cells to survive in embryos is not clear and is the subject of continuing investigation. In some cases the tumour is not eliminated, but instead kills the chick, either in embryonic life, or shortly after hatching. The destruction around the eighteenth day of incubation of foreign tissue cultivated on the chorio-allantoic membrane of the chick embryo has been attributed to an immune reaction[7]. However, in the absence of any direct demonstration of antibody in chick embryos this interpretation remains in doubt.) Such birds were shown to possess the capacity to form antibody to the tumour.

Forty-three chick embryos on their eleventh day of incubation were injected with 0·04 ml. of a 1 : 100 dilution of mouse ascitic fluid which contained about 10^8 tumour cells per ml. Incubation of the embryos was continued together with sixteen non-injected controls. Of those injected, nineteen died within 48 hr., presumably from tumour cell emboli; of the remainder, nine selected at random were killed during the sixteenth to eighteenth days of incubation, and their livers, brains and hearts were examined in microscopic section. A portion of the liver of each of the embryos killed on the seventeenth and eighteenth days was crudely minced and injected intraperitoneally into two mice. Of the embryos examined, all but one contained living tumour in their organs. In some embryos, roughly 2 per cent of all cells in the liver were found to be tumour cells. In all cases in which tumour cells were seen microscopically in liver sections, transfer of liver mince to mice was followed by the development of typical ascites tumour.

Eight of the embryos injected with tumour and eight controls hatched and lived through to adulthood. At first the injected chicks were somewhat smaller and less vigorous than the controls; but by the age of one month these differences had disappeared. The sera of the birds were tested periodically for their ability to agglutinate a standard suspension of washed ascites tumour cells (0·25 ml. diluted serum plus 0·05 ml. of 1·5 per cent cell suspension read after 20 min. in Kahn shaker at room temperature). No antibodies were detectable until the age of five weeks, when low-titre agglutinins begin to appear in normal chickens. At this time the birds were divided into two groups, *A* and *B*, each consisting of four injected and four control animals. The members of group *A* were injected periodically with the washed cells from 0·2 ml. of ascites fluid while those of group *B* were not.

In Fig. 1 are shown the resulting serum dilution titres for agglutinins against a standard suspension of ascites cells. In group *A*, each pair of points was preceded one week earlier by the immunizing injections of ascites cells. These animals showed strong specific antibody responses whether or not they had contained growing tumour cells during their embryonic life. The small difference shown between chicks of

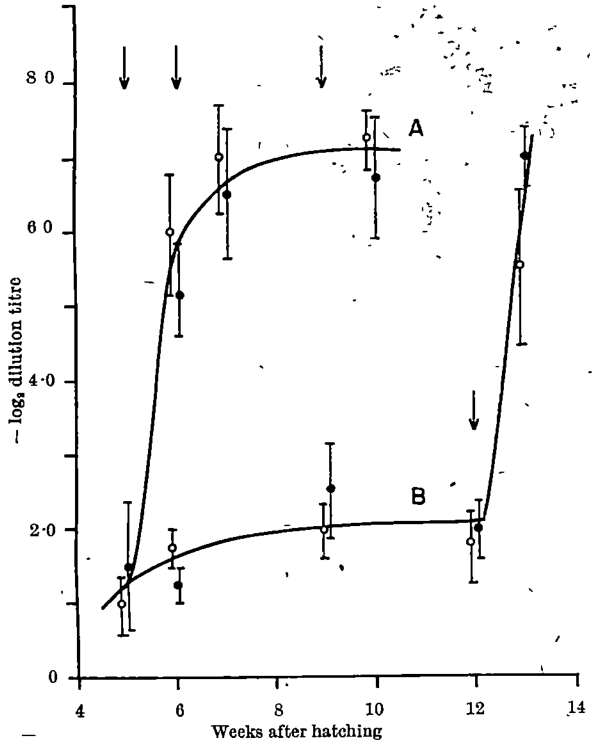

Fig. 1. ●, Chicks from tumour-injected embryos; o, chicks from uninjected embryos. Each point is the mean of four birds (range indicates standard error). ↓, Intraperitoneal injection of washed cells from 0 2 ml. of ascitic fluid

the two classes is not statistically significant. Group *B* animals of both classes developed only low-titre agglutinins until the age of twelve weeks, when a single injection of tumour cells resulted in a sharp rise in titre in all animals.

It is clear from these experiments that the presence of foreign cells growing in an animal during its embryonic life is not in itself a sufficient condition for the production of a state of permanent tolerance to the cellular antigens. In the case of tolerance following the introduction of homologous cells, permanent survival of the cells could result not only in persistence of the antigens involved but also in great increase in their amount. Such cells might liberate antigen over the period of maturation of the animal, producing a type of tolerance not fundamentally different from the condition produced postnatally in rabbits[8-10] by the administration of simple antigens.

Resting Tension in Snail Muscle

WHEN weighted with even a very small load, the smooth retractor of the snail's pharynx extends to great lengths[1]. This phenomenon has been taken to indicate an almost complete absence of elastic material in parallel with the fibres of that muscle[2]. In connexion with work to be published elsewhere, we have been able to show that the snail muscle actually has a parallel elastic component which produces resting tension at appropriate lengths.

It is well known that above a length which coincides with that at which maximum isometric tension is developed, frog sartorius muscle exerts a resting tension[3]. We find that precisely the same is true of the snail muscle. Maximum isometric tension is produced at about 40 mm. and decreases on either side of that length (upper curve, Fig. 1). Resting tension appears at any lengths greater than the optimum length for isometric tension (lower curve, Fig. 1). But in comparison with its own maximum isometric tension or with the resting tension exerted by frog sartorius, the highest value for the resting tension of the snail muscle is small. This is explained by the dimensions of the snail muscle: it weighs only 30–40 mgm. and at a length of about 50 mm. its cross-section is very small. Although at such a length the active muscle develops tension of the order of 20 gm., the resting muscle may tear at approximately 8 gm.—a breaking stress of 1·5 kgm./cm.^{2}, which points to the presence of a reasonable amount of parallel elastic material.

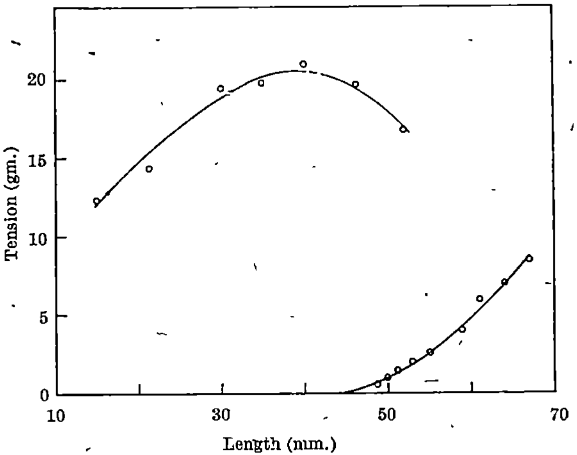

Fig. 1. Tension–length diagram of the pharynx retractor muscle of *Helix* at 14° C., during isometric contraction (upper curve) and at rest (lower curve)

The length–tension curve during isometric contraction in Fig. 1 also shows that the snail muscle can still produce appreciable tension down to lengths less than 12 mm. (30 per cent of its optimum length). It thus has a remarkably wide working range: frog sartorius at the equivalent short length develops no active tension at all[3]. The wide working range of the snail muscle probably explains why the existence of its resting tension has not been hitherto clearly demonstrated.

We conclude that snail muscle (and most likely other types of smooth muscle) can exert resting tension at appropriate lengths. This, together with evidence we have obtained from studies of tension changes resulting from quick stretch of resting muscle, force–velocity relations of active muscle, and shortening heat production, strengthens the view that the mechanical properties of smooth and striated muscle do not differ fundamentally.

Experimental Maturation or Ageing of Collagen in Rabbits' Ears

In the course of a study of direct connective tissue changes, observations were made which have a bearing on the problem of ageing of collagen.

Rabbits' ears were subjected to rhythmical stretching and relaxing movements (20,000–80,000) by mechanical means. Histological examination revealed a thickening of the collagen fibres which were more wavy, crinkled and often fragmented. Although the spaces between the loosened fibres in the stretched ears were larger and more numerous than in the controls, the general appearance was that of a greater homogeneity of the whole corium. A cellular infiltration and in particular an increase in the number of fusiform, that is, mature, fibroblasts were noticeable.

The most interesting finding, however, was that of 'clearing' or 'dispersal' of the amorphous ground-substance coating of the fibrils seen on the electron microscope photographs. A count of individual fibrils in five classes, into which they were divided according to the lesser or greater amount of coating material which allowed the unaltered periodicity of cross-striation of individual fibrils to be distinguished, or obscured it in varying degrees, showed a shift towards a distribution found in aged tissues.

A decrease, with increasing age, in the amount of the amorphous substance coating the fibrils in other tissues has been reported[1-3].

Our findings indirectly confirm those of Angevine[4], who found in his histological preparations that when a stress or tension is exerted on the rabbit's ear by pulling, there is a mechanical stimulation of fibroblasts; they form in greater abundance, and the direction of stress determines the direction in which they are distributed. Banfield[5] found that the extractability with acetic acid of collagen from human skin, tendon and dura varied with age. Similarly the swelling of human Achilles tendon in acetic acid decreased as age increased.

Other alterations in the properties of collagen variable with age were found by Verzár[6]. The tendons of the tails of white rats show after the fifth month a thermo-elastic contraction which increases progressively with ageing. Similarly the skin shows an increasing thermo-elastic contraction after the third month.

Disregarding the mechanical effects, it is reasonable to assume that thermal and *p*H changes—though probably on a small scale—have taken place in the stretched ears. The underlying morphological changes brought out in the histological and electron microscope studies in our series may belong to the same category of events as those occurring with thermal and chemical contraction[7,8]. The degree of these may depend on the degree of the stimulus applied.

Although the nature of the coating material, its dissolving or removal or translocation are all matters of conjecture, it is thought that a correlation of changes occurring after thermal, chemical or other stimuli, with the connective tissue changes in our series due to experimental wear and tear, may throw some light on processes underlying ageing.

A detailed account of the method and results will be published elsewhere.

Effect of Molybdenum Deficiency on Catalase and Peroxidase in *Neurospora*

Molybdenum has been identified as a constituent of nitrate reductase in some bacteria[1], fungi[2-4] and higher plants[5], and the micro-nutrient was shown to undergo a valence change involving Mo^{6+} and Mo^{5+} during the enzymatic reduction of nitrate[6]. Apart from its role in nitrate reductase, it is known that molybdenum is also important for other metabolic processes in plants. When ammonium is the sole source of nitrogen, nitrate reductase does not usually form in plants, and the molybdenum requirement, although considerably reduced, is not completely eliminated.

In this communication it is shown that a deficiency of molybdenum in *Neurospora crassa* reduced the catalase and peroxidase enzymes in cell-free extracts of the felts by 1/10 and 1/4 respectively of that in normal tissues.

Neurospora crassa wild type 146 (microconidial type) was grown in a modified Fries medium containing ammonium nitrate as the source of nitrogen[2]. The removal of molybdenum from the basal culture solution was achieved by the copper coprecipitation methods[7]; molybdenum (20 μgm. per litre) was then added back to some of the purified culture media which served as controls. The media were dispensed in 200-ml. amounts in 1-litre Erlenmeyer flasks, inoculated with a spore suspension of the fungus contained in triple-distilled water, and incubated for four days in the dark at 28° C. The mycelial mats from the normal and molybdenum-deficient cultures were collected separately in a Büchner funnel, washed well with triple-distilled water, and frozen for 1–3 hr. at − 15° C. They were ground with a cold pestle

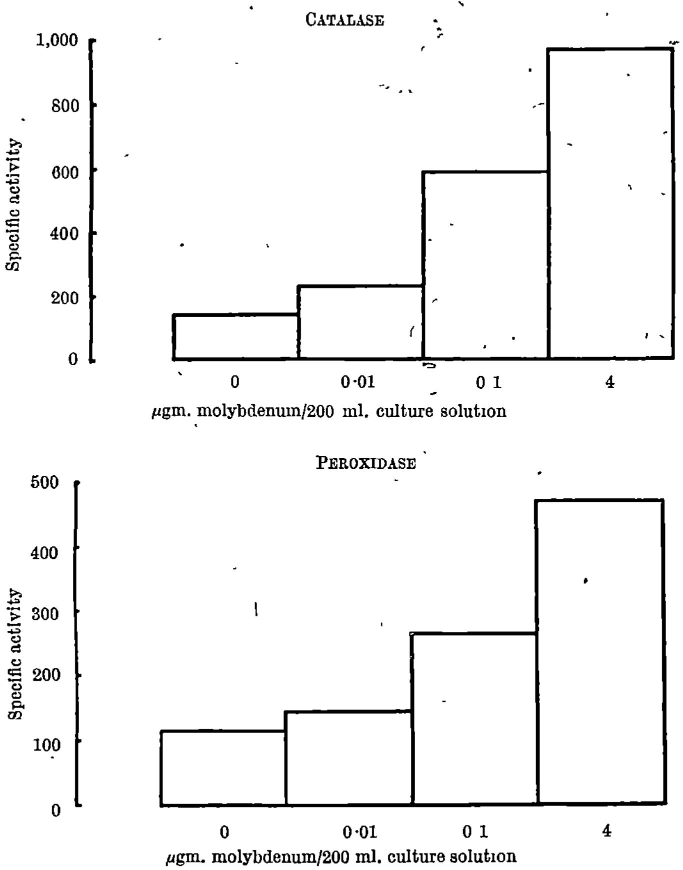

Fig. 1

and mortar with three times their weight of cold 0·1 *M* phosphate buffer (*p*H 7·5) and then in a TenBroeck glass macerater. The solutions were centrifuged at 2,000 *g* for 10 min. at 4°.

The protein contents of the extracts were determined by Lowry's method[8]. Catalase was determined in aliquots of the extracts by the perborate method[9] and the enzyme activity is expressed as μmoles perborate degraded in 5 min. per mgm. protein. The peroxidase was determined by the method of Smith *et al.*, as the change in log I_0/I_l of 0·001 per minute calculated from 15 to 75 sec. per mgm. protein[10].

Molybdenum deficiency in *Neurospora* resulted in a 40–55 per cent reduction in growth. The effects of the deficiency on the two iron enzymes are shown in Table 1.

A deficiency of molybdenum in *Neurospora* significantly reduced the two iron enzymes; the effect on catalase is more severe than for peroxidase.

Table 1. EFFECT OF MOLYBDENUM DEFICIENCY ON CATALASE AND PEROXIDASE IN *N crassa*

Enzyme	Expt.	+Mo	−Mo	Reduction: as per cent of controls
Catalase	1	640	193	30
	2	732	158	22
	3	756	83	11
Peroxidase	1	330	134	40
	2	138	63	45

+Mo cultures contained 20 μgm molybdenum per litre. Enzyme units given in text.

In Fig. 1 are shown the effects of adding graded amounts of molybdenum to the basal culture solution on the two enzymes present in cell-free extracts of the felts. Increasing the molybdenum content of the medium is paralleled by increases in the two enzymes; the maximum activity is reached when 4 μgm. molybdenum is given per 200 ml. culture solution.

When molybdenum was added aseptically *in vivo* to the omit-molybdenum cultures after three or four days' growth, the two enzymes were adapted to the added micronutrient and were reconstituted within 24 hr. to about 70 per cent of those in the control cultures. It was not possible to reconstitute the two enzymes by adding 0·1 μgm. or 1 μgm. of molybdenum to homogenates of the molybdenum-deficient felts. Mixing extracts of normal with those of molybdenum-deficient felts proved that there was neither an inhibitor in the deficient felts nor an activator in the normal ones.

Whether molybdenum is a constituent of the iron enzymes or whether the effect is an indirect one is as yet unknown. It is established that molybdenum deficiency results in a reduction in certain flavoprotein enzymes which produce hydrogen peroxide[11]. A deficiency of the micronutrient could therefore result in a low production of hydrogen peroxide in the fungus so that catalase and peroxidase, which are known to be adaptive enzymes, would thus be depleted. Experiments now in progress may elucidate the role of molybdenum in relation to the two iron enzymes.

Cumulative Effect of Sub-Lethal Doses of Insecticides on Houseflies

THE effectiveness of repeated small doses of insecticides is of considerable practical importance. For example, mosquitoes and houseflies entering houses treated with residual insecticides make intermittent contacts with deposits, and tsetse flies may receive a succession of doses when applications of insecticides are made from aircraft on a number of parallel runs in each day's sortie, and the area treated at the end of one sortie is re-treated at the beginning of the next. Hoffmann *et al.*[1] exposed houseflies intermittently to small amounts of DDT residues and found that the longer the intervals between exposures the greater the number of flies that survived. There is, however, little quantitative information, and the experiments summarized below were designed to determine the cumulative effect of sublethal doses of insecticides on houseflies.

Flies for the experiments were taken from a normal laboratory colony with no previous experience of insecticides. Females only were used; they are less susceptible than males, and although their susceptibility decreases during the first four days after emergence it remains fairly constant for the next week or more. Small measured volumes of each insecticide solution were applied to the dorsal surface of the thorax of individual flies from a microburette similar to that described by Kerr[2]. The concentration of each insecticide in kerosene (0·25 per cent gamma-BHC, 1 per cent DDT, 0·07 per cent dieldrin, and 0·25 per cent 'Diazinon') was selected so that a range of kills for the calculation of the *LD*50 was obtained with volumes of 0·029–0·058 µl. Breeding, treatment and storage after treatment were all at 25° C.

In the first series of experiments, the volumes of insecticide solutions were applied in two equal doses with an interval of 0, 24 and 48 hr. between them. Other batches of flies from the same culture and of the same age were given the two doses on the second and third day of each experiment to check variation in susceptibility with age. Results of one series of experiments are summarized in Table 1; repeat experiments provided essentially the same results. The two doses of DDT, dieldrin and 'Diazinon' were fully cumulative even with an interval of 48 hr. between the application of the first and second dose, whereas when 24 or 48 hr. elapsed between the application of the first and second dose of gamma-BHC, mortalities were significantly lower than when the two doses were applied one immediately after the other. It would appear that approximately 50 per cent of the first dose had been rendered ineffective by the time the second dose was applied 24 or 48 hr. later.

In the second series of experiments smaller volumes of 0·009 µl. of each insecticide solution were applied daily to individual flies, and variation in susceptibility with age was checked by treatment of other batches of flies from the same culture on various days. Results of one set of experiments are summarized in Table 2, and are similar to those obtained on other occasions.

When mortality counts had been made 24 hr. after the application of the sixth daily dose of gamma-BHC, survivors from the various replicates were pooled and then divided at random into batches. Different doses of gamma-BHC were applied to each batch and the *LD*50 determined. The survivors had an *LD*50 of 0·075 µgm. gamma-BHC per fly (ignoring the six daily doses) compared with 0·094 µgm. for untreated flies of the same age from the same culture. In the same way it was found that the survivors from the six daily doses of DDT had an *LD*50 of 0·15 µgm. DDT per fly (again ignoring the daily doses) compared with 0·39 µgm. for untreated flies of the same age from the same culture.

Table 1

Age of flies at first dose	Time interval between the two doses	*LD*50, µgm. insecticide per fly			
		Gamma-BHC	DDT	Dieldrin	'Diazinon'
4–5 days	48 hr.	0·148	0·492	0·028	0·100
4–5 ,,	24 ,,	0·146	0·465	—	—
4–5 ,,	0 ,,	0·104	0·450	0·027	0·103
5–6 ,,	0 ,,	0·112	0·486	—	—
6–7 ,,	0 ,,	0·101	0·475	0·028	0·098

Table 2

Dosages are in µgm. insecticide per fly; *LD*50's are for flies from the same culture

	Age of flies (days)	3–4	4–5	5–6	6–7	7–8	8–9
Gamma-BHC	Cumulative dosage	0·023	0·045	0·068	0·090	0·113	0·135
	Cumulative per cent kill	0	0	0	0	1	1
	*LD*50	0·092	0·105	—	—	—	0·092
DDT	Cumulative dosage	0·09	0·18	0·27	0·36	0·45	0·54
	Cumulative per cent kill	0	0	1	1	11	20
	*LD*50	0·32	0·40	—	—	—	0·39
Dieldrin	Cumulative dosage	0·006	0·013	0·019	0·025	0·032	
	Cumulative per cent kill	0	0	2	16	42	
	*LD*50	0·022	0·027	—	—	0·024	
'Diazinon'	Cumulative dosage	0·023	0·045	0·068	0·090	0·113	
	Cumulative per cent kill	0	0	4	20	60	
	*LD*50	0·087	0·100	—	—	0·094	

In no case were the daily doses of one-fifth to one-quarter of the *LD*50 fully cumulative; but the degree of tolerance for the four insecticides varied considerably, being lowest for 'Diazinon' and increasing through dieldrin and DDT to a high value for gamma-BHC. In fact, the doses of gamma-BHC had little cumulative effect; kills after six doses were negligible, and the dosage required to kill 50 per cent of the survivors was nearly as much as that required to kill the same proportion of untreated flies.

It is evident that houseflies from a normal strain have the ability to eliminate, metabolize or store in a harmless condition, to a greater or lesser extent depending on the insecticide, a proportion of the absorbed insecticide provided that the dosage is sufficiently low. The results of these experiments appear to substantiate biologically the biochemical findings of Perry and Hoskins[3] that susceptible, as well as DDT-resistant, flies are able to detoxify DDT, and those of Oppenoorth[4] and Bradbury and Standen[5] that susceptible flies can rapidly metabolize gamma-BHC. The significance of this ability of normal flies to metabolize insecticides in relation to the development of resistance, however, must be determined by further research.

Interspecific Competition in Higher Plants

THE results of experiments on interspecific competition between vegetable crops and annual weeds suggest that a relationship exists between the crop weight and weed weight per unit area when the relative density of the two species is varied. The relationship appears to be of the type:

$$(X-Xo)(Y-Yo) = C \qquad (1)$$

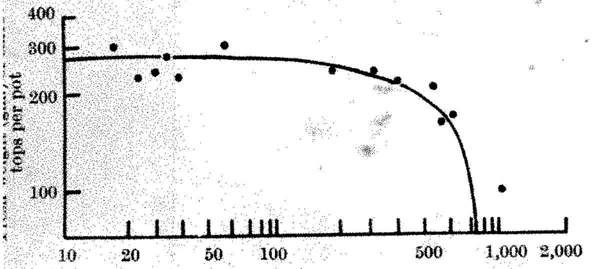

Fig. 1. Fitted curve: $(x - 3{\cdot}10)(y - 2{\cdot}45) = 0{\cdot}054$

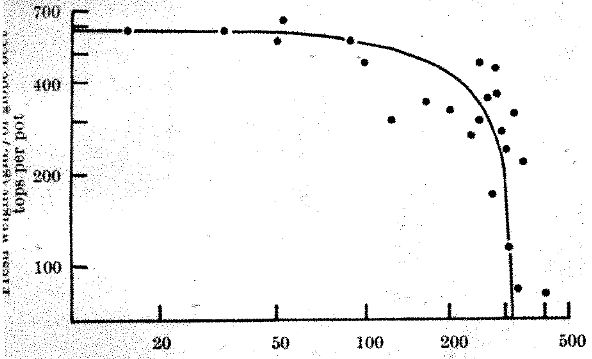

Fig. 2. Fitted curve: $(x - 2{\cdot}53)(y - 2{\cdot}82) = 0{\cdot}27$

where *Xo* and *Yo* are the logarithms of the yields of given numbers of plants of species *A* and *B* respectively, grown separately in a given area, and *X* and *Y* are the logarithms of the corresponding yields when the two species are grown together in the same area. The value of *C* will depend upon the two species concerned and the environment.

Fig. 1 illustrates the relationship obtained in a pot experiment on competition between carrot and chickweed (*Stellaria media* (L.) Vill.). The carrot stand was the same in each pot and the seed was sown on one date. The various weed weights were obtained by varying the weed density or the sowing date. The manner in which the various weed weights were obtained has not obviously affected the relationship. In another experiment three densities of globe beet were used, all sown at one date, and one density of annual nettle (*Urtica urens* L.) sown on two dates (at crop sowing and crop germination). Fig. 2 illustrates the results obtained.

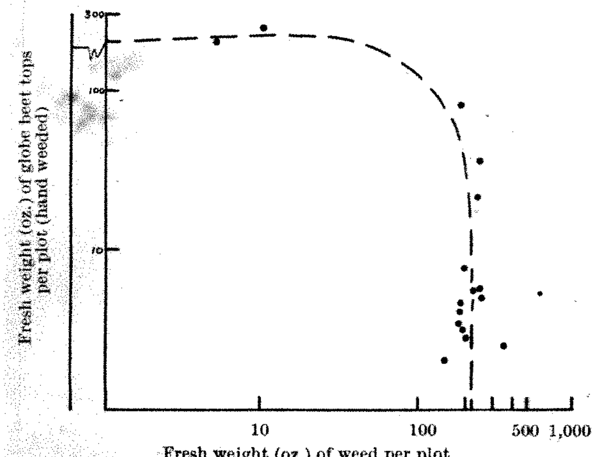

Fig. 3. Possible curve of hyperbolic type, drawn in by eye

A field experiment with a naturally dispersed and mixed weed population and a crop of globe beet grown in rows yielded results which tend to confirm the results of the pot experiments. However, the absence of values in the region of maximum curvature of the graph plotted in Fig. 3 does not allow a detailed study of the trend. The various weed weights were obtained by reducing the natural weed population by applications of a contact pre-emergence herbicide at different rates.

The results presented by Mann and Barnes[1] in a series of papers on the competition between barley and certain weeds and between rye-grass and clover may be plotted to show that the relationship between the logarithms of the weights per unit area of species *A* and *B* can be adequately described by a curve of type (1).

The practical point of interest is the amount of weed a crop can tolerate before competition starts. Preliminary results suggest that the weight of weed in a crop is linearly related to the percentage cover of the weed (at least over a considerable range of cover). It is hoped that cover assessments, which are non-destructive and easily obtained, may prove useful in determining the time of onset of competition. Such information could then be used for assessing the best time to apply weed control measures and to evaluate present weed control practice.

I am indebted to Mr. H. A. Roberts for his co-operation in the field experiment described, and to Mr. J. A. Nelder for his help with the mathematical aspects of this communication.

Toxicity and Breakdown of 'Hormone' Herbicides

DURING the course of an investigation of the effect of certain 'hormone' herbicides, when applied to the rooting medium, on the growth and nodulation of white clover (*Trifolium repens*), some interesting features emerged on the relative toxicities of these compounds. The substances utilized were the sodium salts of 24*D* (2 : 4-dichlorophenoxyacetic acid), *MCPA* (2-methyl-4-chlorophenoxyacetic acid), 245*T* (2 : 4 : 5-trichlorophenoxyacetic acid), 24*DB* (γ-(2 : 4-dichlorophenoxy)butyric acid) and *MCPB* (γ-(2-methyl-4-chlorophenoxy)butyric acid). Their action on the white clover was determined by growing the plants in (*a*) aseptic agar culture in test-tubes and (*b*) soil culture in pots. The agar rooting medium was the nitrogen-free formula described by Thornton[1] and the soil was John Innes compost which had been allowed to weather for a year in the open air. The plants were inoculated with a known effective strain of *Rhizobium trifolii*. The hormone substances were incorporated in the agar in the appropriate concentrations. In the case of the pot experiment, the soil was air-dried, and 100 c.c. of the chemical at the appropriate

Control	22	22	305	305	18	18	1,359	1,359

(*a*) Concentration 5·0 p.p.m. (acid equivalent).
(*b*) Concentration 12·0 p.p.m. (acid equivalent).

concentration was added to each pot containing 175 gm. of soil. Each pot was stood in a Petri dish of water to eliminate the effects of leaching. There were seven tubes and seven pots per treatment.

The plants were grown for ten weeks in a cool greenhouse and then harvested. The results are shown in Table 1.

From Table 1 it is clear that in the tube experiment the order of toxicity is (1) 24*D* most toxic, (2) *MCPA*, (3) 245*T*, (4) *MCPB*, and (5) 24*DB* least toxic. This may be looked upon as a measure of their true toxicity. In the soil, however, the order of toxicity is (1) 245*T*, most toxic, (2) *MCPA*, (3) *MCPB*, (4) 24*D*, and (5) 24*DB* least toxic.

From the tube experiment it can be seen that 245*T* in itself is not more toxic than 24*D* or *MCPA*. It is postulated that 245*T* owes its greater effectiveness in soil to its greater persistence there. Similarly, *MCPA* lasts[2] much longer in the soil than 24*D* and it therefore is much more effective.

The toxicity of the *MCPB* in the soil may be attributed to its breakdown in the soil to *MCPA* by micro-organisms possessing the β-oxidizing system. The possibility of such a breakdown has already been mentioned by Wain[3]. The relative ineffectiveness of 24*DB* may be attributed to its breakdown by similar organisms to 24*D*, which is afterwards rapidly rendered innocuous by other soil micro-organisms.

Our thanks are due to Messrs. May and Baker who supplied the 24*DB* and *MCPB* for experimental purposes. It is hoped that these experiments will be published in more detail elsewhere.

Impression Methods for the Study of the Distribution of Deposits and Organisms on Plant Surfaces

THE use of transmitted illumination in microscopic studies of chemical or biological material on plant surfaces is limited by the opaqueness of the plant tissues. The methods described by Crisp and Thorpe[1] and Bryson[2] for obtaining transparent impressions of various surfaces in gelatin and cellulose acetate respectively have been successfully applied to the study of deposits on leaf surfaces. Such impressions can be readily enlarged and examined visually or photographically; simple 35-mm. projection provides ample magnification for general distribution studies of materials on plants, but for more detailed studies much higher magnification can be used.

Leaf impressions are obtained by pressing the leaf to be examined on to a cellulose acetate film (0·005 in. thick) previously moistened with a 5·0 per cent solution of cellulose acetate in acetone. When the impression has hardened (approx. 60 sec.) the leaf is carefully peeled off. In a similar manner gelatin impressions may be obtained on a glass slide coated with a warm solution of gelatin in water in approximately equal proportions. These impressions may take up to 30 min. to set hard.

By one or other of these methods it is possible to examine almost all solid spray deposits on plant material. Since many of the organic insecticides and fungicides are soluble in acetone the cellulose acetate method cannot be used to detect such materials, while for similar reasons gelatin is not suitable for water-soluble deposits. A gelatin impression (Fig. 1) illustrates a deposit of BHC crystals on the upper surface of a broad-bean leaf; these crystals are relatively large, but the distribution of crystals of the order of 1·0μ has been studied by this method.

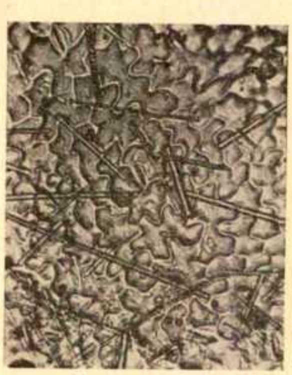

Fig. 1. (× 82·5)

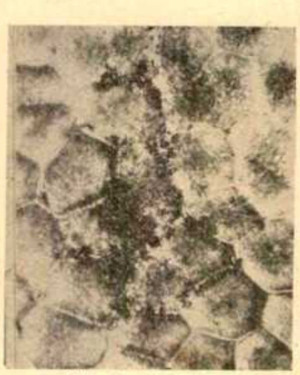

Fig. 2. (× 115)

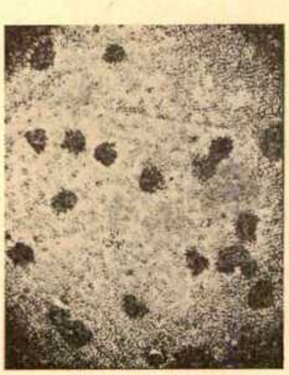

Fig. 3. (×17·5)

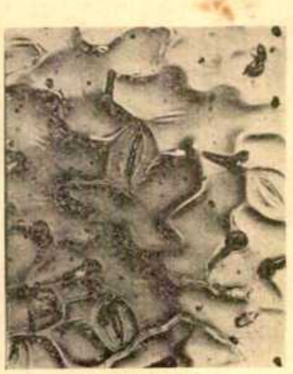

Fig. 4. (× 185)

Spray deposits of copper and lime sulphur are neither crystalline nor strongly coloured, and for these reasons are not clearly distinguishable in an impression. They are, however, completely removed on to the surface of a cellulose acetate impression and may be developed by treating the impression with a suitable solution which converts the deposit into a more highly coloured compound. Thus a solution of sodium diethyldithiocarbamate converts copper to a dark brown complex and lead acetate solution produces a black deposit of lead sulphide from lime sulphur. Fig. 2 is a high-power photomicrograph showing the distribution of copper from a single spray droplet (approximately 100μ diameter) of Bordeaux mixture on the upper surface of a cyclamen leaf. The particles of copper fungicide have collected in the cuticular depressions at the edges of the epidermal cells. Fig. 3 is a low-power photomicrograph of the deposit produced by discrete drops of 32 per cent lime sulphur on the upper surface of a broad-bean leaf, and it demonstrates the value of the method in rapidly assessing the macroscopic distribution of spray deposits. The use of the methods is not restricted to leaves, but on other surfaces, such as fruit or bark, difficulty may be experienced in applying even pressure to a sufficiently large area. In such cases a satisfactory method is to remove strips of the surface before impressing them.

The method may also be used for studying the distribution and development of fungus spores, which are removed in a cellulose acetate impression of a leaf surface and can be stained with a suitable dye as illustrated in Fig. 4, which shows the distribution of germinating spores of *Botrytis fabae* stained with saffranin on a broad-bean leaf. The method is very useful in studying the range of action of fungicides, since a single impression can show both spore development and the distribution of the fungicide. Population studies of small animals such as mites on plants can be made ; all stages of the mites are removed from the leaf surface in cellulose acetate and are easily distinguishable under simple projection.

Lack of Christmas Factor in Horse Plasma

Bell, Archer and Tomlin[1], using the thromboplastin generation test, recently found the prolonged clotting time of horse blood to be due to a deficiency of antihæmophilic factor. However, Soulier and Larrieu[2] have used horse plasma as a source of this factor. The thrombin generation test[3,4] is useful in differentiating between classical hæmophilia and Christmas disease[5]. Applied to citrated horse plasma (containing 130,000 platelets per c.mm.) the following results were obtained (Fig. 1).

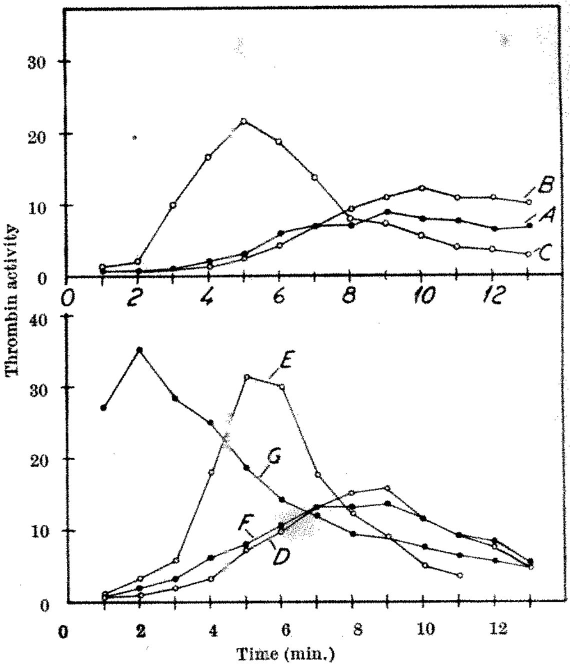

Fig. 1. Thrombin generation in horse plasma. *Abscissa*, reaction time in minutes ; *ordinate*, reciprocal clotting time of fibrinogen solutions expressed as $600/t$ (t in sec.)

Curve *A* shows the thrombin generation in 1 ml. normal horse plasma. The addition of 0·2 ml. plasma from a patient with Christmas disease did not improve the results (curve *B*). Addition of normal human serum (curve *C*) made the thrombin generation normal, whereas barium sulphate absorbed normal human plasma without effect (curve *D*). After the addition of 0·2 ml. plasma from a patient with classical hæmophilia (AHF deficiency) the thrombin generation became normal (curve *E*), whereas the addition of plasma from a patient with Christmas disease and classical hæmophilia was without effect on the thrombin formation (curve *F*). Addition of a preparation of Christmas factor made according to Aggeler *et al.*[6] produced a very rapid generation and a high concentration of thrombin (curve *G*).

Apparently the defect in the thromboplastin system of horse plasma is caused by lack of Christmas factor.

This research was aided by grants from Kong Christian den Tiendes Fond and from the Josiah Macy Jr. Foundation, New York (to Dr. Tage Astrup).

A New Blood Parasite in British Pigs

Parasites of the genus *Eperythrozoon* do not appear to have been reported previously as occurring in the pig in Great Britain. In the United States Splitter[1] has recorded two species, *E. suis* and *E. parvum* ; the former causes a disease known as ictero-anæmia in swine. We wish to report the occurrence of ring-like and coccoid structures, closely resembling those described by Splitter, in the blood of British pigs. The organisms are pleomorphic, rods, triangular and dumbbell forms occur ; but ovoid rings or cocci are the most characteristic. The parasites are found in close association with the red cells and may also be extra-cellular. They stain well with Giemsa and may also be detected when numerous with Leishman's stain. Other workers who have kindly examined infected blood smears concur with our opinion that the organisms are *Eperythrozoa*. (We wish to acknowledge the assistance of Dr. June Thurston, Molteno Institute, University of Cambridge, in this respect.) While we are as yet uncertain of the species concerned, it seems likely that the parasite is *Eperythrozoon parvum*.

The organisms have been found in seven splenectomized pigs less than three months old. They have been seen in the blood within nine days of splenectomy and have remained evident for at least seven days. Initially few in number, they increase until a peak infection is reached, then gradually regress. Recrudescences occur, and in one case this was associated with a mild anæmia (haemoglobin-level reduced by 3 gm./100 ml. and red blood cell counts reduced by 2 million per c.mm.) and a mild fever. A number of attempts at culture on bacteriological media and in developing chick embryos, together with transmission to small laboratory animals, have been unsuccessful. Three pig-to-pig transmissions have been accomplished. A detailed account of these experiments will be published elsewhere.

Unexpected Anomalies in the Behaviour of Neutral Red and Related Dyes

The colour base of neutral red, 2-amino-8-N,N-dimethylamino-3-methylphenazine, together with 2-amino-8-N,N-dimethylaminophenazine (the colour base of 'neutral violet' in German usage), the amphoteric 8-amino-2-phenazinol, and 2-amino-7-N,N-dimethylaminophenazine have been made for the first time by unambiguous means: bomb-tube reactions of aqueous ammonia with the corresponding chloro- or bromo-N,N-dimethylaminophenazines, or with the halogenated 2-phenazinol[1]. The phenazines were made by ring closure through the nitro group of the corresponding 2-nitrodiphenylamines, according to the method of Waterman and Vivian[2].

None of the four compounds stained two species of *Amoeba* (*A. proteus* and *A. dubia*), or cells of sarcoma 37 ascites tumour when they were dissolved in dilute hydrochloric acid and the solutions brought to approximate neutrality. The staining power, on the other hand, was retained by the purified colour base of commercial neutral red (obtained by passing the crude dye twice through basic alumina), when this purified sample was likewise dissolved in dilute hydrochloric acid and the solution neutralized.

Analytical figures for carbon and hydrogen of this latter sample corresponded closely to the theoretical for aminodimethylaminomethylphenazine; the infra-red spectrum of the purified commercial base was ambiguous with regard to that of the synthetic 2-amino-8-N,N-dimethylamino-3-methylphenazine. This line of investigation is being continued. The melting points were different, however, for the base from the commercial dye melted with decomposition at 241–245°, while the synthetic base melted without decomposition at 166–167°. Also, the latter gave a brown colour with concentrated sulphuric acid, while the base from the commercial dye gave a green. In addition, the yellow solution of the synthetic base in ether showed a marked green fluorescence on exposure to ultra-violet light which was absent from the ether solution of the less-soluble purified commercial base.

Significantly, it was found possible to obtain forms of all three of the synthetic 2,8-substituted colour bases which gave vital stains when dissolved in dilute hydrochloric acid. These forms were made by dissolving the colour bases in concentrated sulphuric acid, diluting, and precipitating with ammonium hydroxide. The finely divided products were isolated by centrifuging. It is significant that the 2-amino-7-N,N-dimethylaminophenazine did not give a stain when subjected to this process.

The colour bases so obtained contained varying amounts of water, depending on the humidity of the atmosphere in which they were spontaneously dried; but in the instance of the colour base of neutral red, and presumably for the others, this water was not essential to the staining properties, which were retained undiminished when the compound was dried at 110°.

There apparently exists a third form, also, of the colour base of neutral red at least; for dissolving the synthetic compound in concentrated sulphuric acid and neutralizing directly by concentrated ammonium hydroxide, without prior dilution, produces a non-staining form which cannot be converted to the stain by subsequent treatment with sulphuric acid, dilution, and neutralization by ammonium hydroxide.

Both of the first two forms have been shown to be monomers in methanol solution by the Signer method[3].

Further investigation is being undertaken to determine the nature of the structural differences between the three forms.

We wish to acknowledge the technical assistance of Walter G. Hardy, and of Dr. W. C. Alford for molecular weight determinations.

Separation of Carbohydrates by Electrophoresis on Glass Filter Paper

In recent studies on the paper electrophoresis of carbohydrate compounds, we have found that replacing the cellulose filter paper by paper made from glass fibres[1] greatly facilitates the identification of sugars and their derivatives, especially those which are difficult or impossible to detect on cellulose paper.

Sugars, methylated sugars, sugar alcohols, lactones, sugar phosphates, neutral and acidic polysaccharides may be detected by spraying with a solution (0·5 per cent) of potassium permanganate in *N* sodium hydroxide. The more stable methylated methyl glycosides, methylated polysaccharides and acetal derivatives of sugars are readily detected by spraying with a solution (5 per cent) of 1-naphthol in 10 *N* sulphuric acid.

The paper electrophoresis experiments were carried out in a 'sandwich' type of apparatus[2,3]. The glass paper (made with 3 A. fibre and no organic binder)[1], held between two thin insulating sheets of polythene, is placed on a sheet of foam rubber (0·5 in. thick) and clamped between two sheets of plate glass (0·25 in. thick) by means of two simple wooden clamps[2]. The foam rubber enables an even pressure to be applied to the paper[3]. Since evaporation is prevented, cooling need not be applied except when dealing with proteins, in which case the upper glass plate is replaced by one to which has been cemented a 'Pyrex' dish and through which cold water can be circulated[2].

For electrophoretic analysis of carbohydrates, 0·1 *M* sodium tetraborate was used as the buffer, a voltage of 600 was applied and separations were carried out for 0·5–3 hr., depending on the nature of the substances being examined. Ethylene glycol, D-glucose, tetra-O-methyl D-glucose or its methyl glycoside were used as reference compounds. After the separation, the paper, still containing borate buffer, was placed on a glass plate and dried in the oven at 100° and, while still hot, the reagent was applied as a spray in the usual way. With the 1-naphthol reagent mono-, oligosaccharides, methyl sugars, glycosides, sugar acetals, polysaccharides and methyl polysaccharides were located by the appearance of dark blue spots on a white background, while with alkaline permanganate all oxidizable compounds were detected by the appearance of well-defined white or pale yellowish brown spots on a pink or greenish-pink background. The same glass fibre paper chromatogram may be subjected to the alkaline permanganate treatment (this detects all the oxidizable components), and then with the acidified 1-naphthol reagent (this detects sugar derivatives that escape permanganate oxidation).

Many other substances, including the amino-acids, proteins, sterol glycosides, organic acids and phenols, can be separated in the same manner and readily identified by taking advantage of the fact that a wide variety of reagents and conditions may be used for locating the substances on the glass papers.

Using glass instead of cellulose paper, the possibility of combination between polyhydroxy compounds and the paper through a common borate ion is impossible, whereas this is not necessarily the case when cellulose paper is employed. Hence, structural deductions from borate complex formation, as revealed by electrophoresis, are likely to be more reliable when glass paper is used instead of cellulose paper. The method has proved useful in the separation and comparison of *cis* and *trans* C_5, C_6, and C_7 saturated cyclic diols and other cyclic and straight-chain polyols. The steric effect of neighbouring groups and of the nature and size of rings on vicinal hydroxyl groups has also been investigated.

It will be apparent that this method will also simplify certain quantitative determinations which, hitherto, have had to take into consideration material extracted from the cellulose filter papers, and it is also likely that electrophoresis on thick sheets of glass paper will prove to be useful for preparative work.

The glass filter paper can be re-used after a suitable washing treatment, and a further saving can be effected by using glass paper only for the central portion of the chromatogram, with overlapping extensions of cellulose filter paper to make contact with the buffer solution.

Further details of this work will appear elsewhere.

We wish to thank the National Bureau of Standards, Washington 25, D.C., through the courtesy of Dr. R. B. Hobbs and Dr. M. J. O'Leary, for the glass fibre papers.

Spectrum of the Cyclopentadienyl Radical

The great stability of benzene has aroused much interest in the properties of other planar symmetrical cyclic species of formula $(CH)_n$. For even values of *n*, only cyclo-octatetraene is stable, and is of limited interest owing to puckering of the ring[1]. The odd series can exist only as radicals or ions and, while several calculations have been made of their resonance energies[2-4], only $C_7H_7{}^+$ has been observed spectroscopically[5], although the acidity of cyclopentadiene[6] provides evidence for the stability of the ion $C_5H_5{}^-$. Like benzene, both these species have six π-electrons and are expected to have higher resonance energies than the 38 k.cal. predicted for the cyclopentadienyl radical (C_5H_5)[3,4].

Experiments have been carried out on the flash photolysis of both cyclopentadiene and 'ferrocene' (biscyclopentadienyl iron) in the gas phase using the apparatus previously described[7]. Pressures of 1–10 mm. of cyclopentadiene or 1 mm. of ferrocene diluted with 250–750 mm. of inert gas (nitrogen or carbon dioxide) to limit the rise in temperature were used. In all these mixtures, the spectrum shown in Fig. 1 was observed during the photolysis but disappeared rapidly, its half-life being less than 10^{-4} sec. This spectrum consists of two heads at 29,581 and 29,911 cm.$^{-1}$, which are relatively sharp, having widths of about 10 cm.$^{-1}$; this spectrum must presumably be due to the C_5H_5 radical, since it is difficult to visualize any other transient species except atoms which would be formed directly in the photolysis of both these compounds. Furthermore, recent calculations by McEwen and Longuet-Higgins[8] using a semi-empirical molecular orbital treatment predict an E_1'' ground-state for this radical, with an A_2'' first excited state to which a transition would be allowed (transition moment symmetry—E_1'). Neglecting second-order interactions, they find an excitation energy of [illegible]·02 eV. for this state, which is in strikingly good agreement with the observed values of 3·67 and 3·70 eV. Also, they predict that there will be no other states lying below 6 eV., which is in accordance with the absence of further absorption bands above the limit of observation at 2400 A.

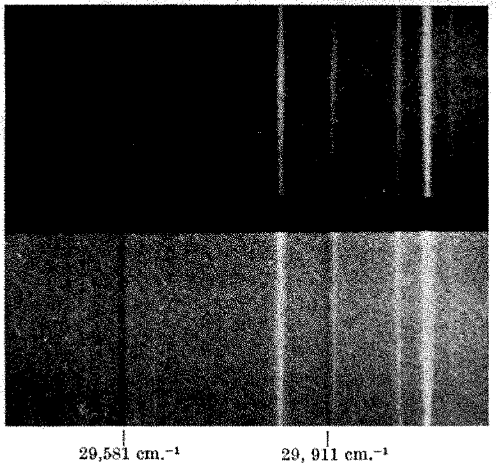

Fig. 1. Absorption spectrum attributed to the cyclopentadienyl radical

The decay of the C_5H_5 radical is accompanied by the appearance of featureless continuous absorption below 3500 A., due to a stable product which has not yet been investigated. In the absence of an inert gas, the rise in temperature due to the light energy absorbed by either cyclopentadiene or ferrocene is insufficient to produce appreciable thermal decomposition; under these conditions, the continuous absorption by the products appears without the intensity of the C_5H_5 spectrum reaching the limit of detection. This increase in the rate of the reactions removing the radical indicates that they have an appreciable activation energy, which is not surprising in view of the high resonance energy expected for C_5H_5. During this photolysis in the absence of inert gas, ferrocene shows strong absorption from iron atoms in the sub-levels of the (x^5D) and (a^5F) states, the latter being intense enough to suggest that the iron atoms might be liberated in this state.

I wish to express my gratitude to Miss K. L. McEwen and Prof. H. C. Longuet-Higgins for permission to quote results from an unpublished paper.

A Test of the 'Redox' Hypothesis of Active Ion Transport

The concept that the electron transfer in the oxidation–reduction reactions of respiration constitutes the driving force for active ion transport has provided the basis for several hypotheses of ion transport[1-7]. All these have in common the quantitative limitation that no more than four univalent ions can be actively transported per molecule of oxygen consumed, because oxygen can accept just four electrons per molecule in its complete reduction.

To test this 'redox' hypothesis of ion transport, simultaneous measurements were made of active ion transport and oxygen consumption by isolated frog skin. Ussing and Zerahn[8] have shown that, with the same solution bathing both sides of an isolated frog skin, the short-circuit current measured, when a counter potential is applied across the skin so as to reduce the spontaneous membrane potential to zero, is equal to the net sodium transport through the skin. Hence the short-circuit current was taken as the measure of active sodium transport. Oxygen consumption was measured polarographically with a vibrating platinum micro-electrode[9].

A total of eighty-seven individual, simultaneous measurements of oxygen consumption and active ion transport was made on the ventral skins of nineteen frogs (*Rana temporaria*). The ratio of ions transported to molecules of oxygen consumed was found to range from 2 to 13 with a mean of 6·93 and standard error of the mean of ± 0·21. In all but five periods this ratio was above 4·0. The experimental error propagated into the determination of a single value of this ratio is estimated to be ± 9 per cent.

These results are incompatible with the 'redox' hypothesis of ion transport in which molecular oxygen is the electron acceptor. Similar results in this same tissue have recently been obtained by Zerahn[10].

Active sodium transport through the frog skin is augmented by neurohypophyseal preparations of mammalian origin[8]. We find in all but one of sixteen experiments that this effect is associated with a simultaneous increase of oxygen consumption by the stimulated membrane. Thus the mean rates of sodium transport for the sixteen periods just before and the sixteen periods just after addition of neurohypophyseal preparations were 1·69 and 2·76 μequiv./cm.^{2}/hr. respectively, the mean difference was 1·07 and its *S.E.* ± 0·089 and $P < 0·001$. The mean figures for oxygen consumption for the same periods were 0·278 and 0·341 μmole/cm.^{2}/hr., the mean difference was 0·063 and its *S.E.* ± 0·0129 and $P < 0·001$. If the one experiment in which no stimulation of oxygen consumption was observed is excluded, the mean ratio of increment of sodium transport to increase in oxygen consumption following stimulation of the skin with neurohypophyseal preparations was 21·1 ± 3·0 sodium ions transported per molecule of the increment of oxygen consumed. Though such a calculation is open to some criticism[11], this mean figure of the ratio of increase in sodium transport to increase in oxygen consumption represents the best estimate possible at present of the actual stoichiometric relationship of ion transport to oxygen consumption by the fraction of cells in this tissue engaged in the ion transport process.

The minimum energy required for the active ion transport process constitutes 8 and 10 per cent of the total energy available to the tissue from aerobic metabolism before and after stimulation with neurohypophyseal preparations, respectively, and 22 per cent for the increment of ion transport and oxygen consumption following hormonal stimulation. Thus no inconsistency is encountered when the energetics of the observed rates of ion transport are considered.

Previous attempts to evaluate the relationship of ion transport to oxygen consumption in this tissue have been made. Stapp and Lund[12] obtained values close to 4 but realized that, as they were not using a totally short-circuited skin preparation, their results gave only a minimal value. Linderholm[13] has estimated this relationship and his results give a value of 3·28. However, his oxygen and ion transport measure nents were not made simultaneously on the same skin but were mean figures. More important, the skins used in his study gave very low rates of ion transport averaging 0·7 μequiv./cm.^{2}/hr. as compared with our higher values recorded above. Thus, even though our values for oxygen consumption are higher than his, the ion transport rates were sufficient to give the higher ratios produced here.

The results indicate that the 'redox' hypothesis of ion transport in which oxygen is the final electron acceptor is quantitatively insufficient to account for observed rates of ion transport and oxygen consumption by the isolated, short-circuited frog skin.

The full paper will be published in due course.

Formation of Hydroperoxides from Nucleic Acids by Irradiation with X-Rays in Aqueous Systems

IN the course of our studies of the chemical effects of X-rays on nucleic acids in aqueous solutions[1], we have had occasion to measure the amounts of peroxide produced. Two methods were employed: (*a*) the reaction with titanium sulphate reagent[2] and spectrophotometric measurement of the resulting complex at 405 mμ; (*b*) the oxidation of potassium iodide[3] and determination of the liberated iodine (I_3^-) by the absorption at 353 mμ. It was found that, in solutions of thymus deoxyribonucleic acid and also of yeast ribonucleic acid irradiated in the presence of oxygen, the yields of total peroxide, as determined by the iodide method, were always greater than those of hydrogen peroxide, estimated by titanium sulphate. This observation can be explained by the presence of organic hydroperoxides in the irradiated nucleate solutions, since it is known that hydroperoxides will oxidize iodide ions, but do not give, in general, the coloured complex with the titanium sulphate reagent.

For example, in the irradiation of deoxyribonucleic acid solutions (0·1 per cent w/v, Signer acid, $p\mathrm{H} \sim 7$) with X-rays (200 kV.), in the presence of oxygen (1 atm.), with a total dose of $\simeq 3 \times 10^4$ rep, the yield of total hydroperoxides was $G = 2{\cdot}5$ (molecules/100 eV.), whereas for hydrogen peroxide $G = 1{\cdot}5$; this gives a difference of $G = 1{\cdot}0$ to be accounted for by organic hydroperoxides.

These hydroperoxides showed a marked post-irradiation decay. In the case of the above-mentioned deoxyribonucleic acid solutions, the disappearance of the organic hydroperoxides could be accounted for on the basis of the occurrence of two simultaneous first-order processes, with half-lives of about 1 hr. and 30 hr. respectively (at 25° C.).

In order to throw some light on the nature of the hydroperoxides in irradiated nucleate solutions, experiments have been carried out with several ribonucleotides and ribonucleosides and also with the corresponding purine and pyrimidine bases. Evidence for the presence of hydroperoxides was obtained in irradiated solutions of uridine-3′-phosphate, uridine, cytidine-3′-phosphate, cytidine and with uracil and thymine; but negative results were found with guanosine-3′-phosphate, the adenosine-3′- and 5′-phosphates, as well as with adenosine and with adenine. Hence, we may conclude that these hydroperoxides are associated with the pyrimidine bases. These experiments suggest that the two different hydroperoxides which are found in the irradiated deoxyribonucleic acid solutions are derived from the two pyrimidine components.

The presence of molecular oxygen during irradiation is essential for the production of hydroperoxides from these compounds. This is in agreement with the general idea that the formation of organic hydroperoxides proceeds through the addition of molecular oxygen to the free radical, $R\cdot$ (formed by the action of a radiation-produced OH radical on the solute, RH), leading to the formation of an organic peroxy-radical $RO_2\cdot$, which, on reduction, can form a more or less stable organic hydroperoxide (RO_2H) [4].

The production of such hydroperoxides from deoxyribonucleic acid and ribonucleic acid may be of considerable importance from a radiobiological point of view; in particular, this may have a bearing on some delayed effects of ionizing radiations *in vivo*.

Work on related and various other compounds of biological importance is in progress.

Full details will be published elsewhere.

Note added in proof. It has now been found that the formation of hydroperoxides from these compounds can also be induced by irradiation of their aqueous solutions with ultra-violet light in the presence of oxygen.

We wish to thank the North of England Council of the British Empire Cancer Campaign and the Rockefeller Foundation for financial support.

Influence of Surface Oxygen in the Activation of Carbonized Coals by Partial Combustion

IT has long been appreciated that surface compounds as well as gaseous oxides are formed when carbons and oxygen interact. Rhead and Wheeler's original suggestion[1] that the so-called surface oxides are intermediates in the overall reaction mechanism is not borne out by more recent work[2,3], which shows that at least a proportion of the oxides should be regarded as by-products of the main reaction.

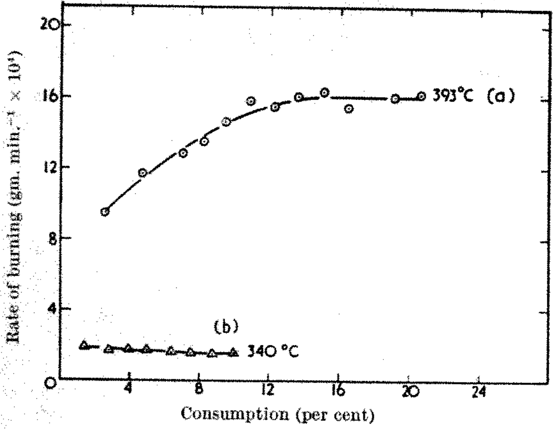

Fig. 1. Relation between rate of burning and per cent consumption for 812° C. char burned at two temperatures at an oxygen partial pressure of 20 per cent of 1 atmosphere: *a*, 393° C.; *b*, 340° C.

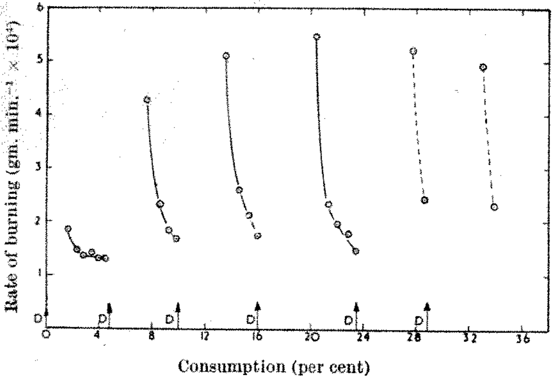

Fig. 2. Relation between rate of burning and per cent consumption for 812° C. char burned at 340° and 7·7 per cent oxygen partial pressure with periodic degassing (*D*) of the fuel in nitrogen at 750° C. Initial charge 3·1 gm. Size-range 7–10 B.S.S.

A study of the slow reaction in oxygen of several carbons covering a wide range of reactivity has shown clearly that surface oxygen can retard the normal development of reactivity of porous carbons accompanying their partial consumption. The reaction was followed by gravimetric estimation of the oxides of carbon in the outflow gases, in which large quantities of oxygen were still present. Under suitable conditions (reactive fuel and low reaction temperature), consumption of the fuel did not lead to the increase in reaction-rate that would be expected as a result of marked activation. For example, the curves in Fig. 1 show the variation in rate of gasification with extent of consumption for one fuel at two working temperatures, namely, 340° and 393° C. In the latter case (curve *a*) the increase in rate with consumption indicates marked activation, whereas in the former (curve *b*) the rate shows little change. The influence of surface oxygen in determining the form of curve *b* was demonstrated by interrupting a run and heating the carbon, in an atmosphere of nitrogen, to a temperature slightly below that of its preparation. This process led to the release of oxides of carbon from the sample. On cooling to reaction temperature and re-admitting oxygen a very high initial reaction-rate was observed which decayed rapidly towards its previous low value. This cycle may be repeated (Fig. 2). With more reactive fuels, exposure to oxygen after degasification often led to uncontrollable temperatures.

The precise mechanism of retardation by surface oxygen is unknown; activation of porous fuels is thought to proceed mainly by an 'opening up' of the internal structure. This presumably goes on while the surface oxides are present on the fuel; but the new surface is not available for rapid combustion until the oxides are removed. This effect would provide a reason, apart from temperature control, for preferring to activate fuels in steam rather than in air or oxygen; for, so far as we are aware, no oxide by-products from the steam/carbon reaction have been reported.

This role of surface oxygen in the practical ignition of a fuel on a grate is probably small if auxiliary sources of ignition are used, since the temperature-range in which the surface oxides would be most influential is rapidly traversed.

Solid-State Reaction in the System $ZrO_2-Al_2O_3-SiO_2$

A number of compositions at 10 per cent intervals along three possible compatibility joins within the system have been heated at 1,650° C. All were formulated from mixtures of the pure oxides and, where applicable, a high-grade natural zircon.

X-ray analysis of calcined specimens of the series of simple oxide mixtures equivalent to compositions along the possible compatibility join ZrO_2—$3Al_2O_3.2SiO_2$ showed each to consist of a binary mixture of zirconia and mullite. The exclusive presence of these two solid phases suggested the validity of the join. Confirmation of the non-existence of the intersecting join Al_2O_3—$ZrO_2.SiO_2$ was provided by the fired nature of the series of compositions along it. The first five members (90–50 per cent Al_2O_3) of the series were found after calcination to comprise ternary mixtures of zirconia, mullite and alumina, while the last four (40–10 per cent Al_2O_3) consisted of ternary mixtures of zirconia, zircon and mullite. If the join were valid, solid-state reaction would have resulted in the production of binary mixtures of alumina and zircon in all cases. The X-ray diffraction charts of compositions made up with natural zircon clearly indicated the disappearance of this phase immediately the valid join ZrO_2—$3Al_2O_3.2SiO_2$ was crossed from the side of zircon to the side of alumina. The absence of zircon in fired specimens of a control composition equivalent to the mixture 60 per cent Al_2O_3, 40 per cent $ZrO_2.SiO_2$, which had been prepared from the simple oxides, and its successful synthesis in similar specimens corresponding to the mixture 30 per cent Al_2O_3, 70 per cent $ZrO_2.SiO_2$, was considered strongly to confirm the indicated location of these compositions within dissimilar compatibility triangles.

A series of mixtures of zircon, alumina and silica corresponding to points along the possible compatibility join $ZrO_2.SiO_2$—$3Al_2O_3.2SiO_2$ were found after calcination to be predominantly binary mixtures of zircon and mullite. Further confirmation of the validity of the join was provided by fired specimens of a composition equivalent to the mixture 40 per cent $ZrO_2.SiO_2$, 60 per cent $3Al_2O_3.2SiO_2$, which was made up from the simple oxides. The X-ray diffraction chart of these specimens showed them to be essentially a mixture of zircon and mullite, an indication that the simultaneous synthesis of the two end members had occurred.

Experimental evidence of the validity of the compatibility joins $ZrO_2—3Al_2O_3.2SiO_2$ and $ZrO_2.SiO_2—3Al_2O_3.2SiO_2$ points to the existence of the three compatibility triangles or sub-systems $ZrO_2—3Al_2O_3.2SiO_2—Al_2O_3$, $ZrO_2—ZrO_2.SiO_2—3Al_2O_3.2SiO_2$ and $ZrO_2.SiO_2—SiO_2—3Al_2O_3.2SiO_2$ within the ternary system $ZrO_2—Al_2O_3—SiO_2$. The fired nature of the specimens of the three series studied gave no indication of ternary compound formation on either of the two valid joins or within the compatibility triangles $ZrO_2—3Al_2O_3.2SiO_2—Al_2O_3$ and $ZrO_2—ZrO_2.SiO_2—3Al_2O_3.2SiO_2$. A final composition within the compatibility triangle $ZrO_2.SiO_2—SiO_2—3Al_2O_3.2SiO_2$ indicated that it also was free from additional compound formation. Evidence of partial fusion was apparent in compositions at the high $—ZrO_2.SiO_2$ end of the series $Al_2O_3—ZrO_2.SiO_2$ and $ZrO_2.SiO_2—3Al_2O_3.2SiO_2$. These compositions are in the vicinity of the binary eutectic between alumina and zircon at about 20 per cent Al_2O_3 and 1,680° C., previously reported by Rea[1]. Glass formation was associated with considerable decomposition of the zircon present. The results obtained are only partially in agreement with those of a recently published investigation of solid-state reaction in the quaternary system $MgO—Al_2O_3—SiO_2—ZrO_2$ [2]. The earlier investigation was carried out at considerably lower temperatures.

A more detailed account of this work will be published elsewhere.

Class II Radio Signals from Venus at a Wave-length of 11 Metres

IN two earlier communications[1], the reception of impulsive radio signals from the planet Venus at a wave-length of 11 metres was reported. These signals have burst-like characteristics somewhat resembling atmospherics from terrestrial thunderstorms and may presumably originate in similar storms on Venus. The bursts are of very short duration, being a small fraction of a second.

The purpose of this third communication is to report the reception at the Ohio State University of radio signals of a distinctly different kind which also appear to come from Venus. For convenience, these signals will be referred to as Class II signals, while the previously reported atmospherics-like signals will be designated Class I signals. The same equipment as described earlier has been used for receiving both types of signals.

The Class II signals are usually of a more sustained type, lasting about 1 sec. or considerably more, and appear to be modulated at an audiofrequency-rate. Modulation frequencies in the neighbourhood of 15, 60, 125 and 150 c./s. have been noted. The emissions are slightly reminiscent of signals from a terrestrial radio telegraph station, and they were at first presumed to be interference from this type of station. However, over many weeks they were observed to appear only when Venus was in the antenna beam of the radio telescope and usually seemed to be strongest when Class I signals were also being received with greatest strength. Sustained signals of several seconds duration have also been observed from Jupiter[2]. These have a very low-frequency modulation of 30 c./s. or lower.

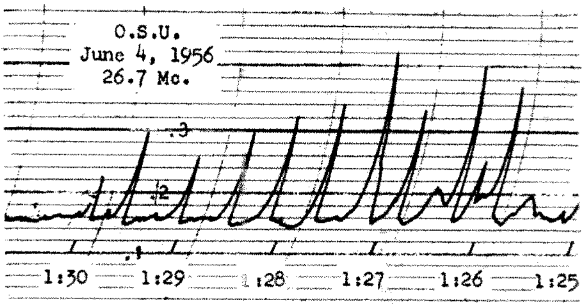

Fig. 1. A series of Class II pulses received on June 4, 1956, at 11 m. wave-length

One of the most prominent Class II signals has a modulation of approximately 125 c./s. and occurs in pulses of about 1 sec. duration. Fig. 1 shows recorder indications of a series of such pulses received on June 4, 1956. The pulses may occur at intervals of a few seconds to a minute or more. In the group shown in Fig. 1 the intervals are mostly between 20 and 30 sec. On some occasions when pulses were being detected, it was observed, by tuning the receiver, that they could be received over a frequency-range of at least 2 Mc./s. Since each pulse has a sloping front and an abrupt termination, the detection over a 2 Mc./s. frequency-range cannot be due to a narrow band pulse swept rapidly in frequency since this would produce a symmetrical pulse having the same shape as the receiver band-pass characteristic. Hence, it appears that the pulses possess a band-width of at least 2 Mc./s.

The pulses are not usually observed for a long enough period of time (rarely more than 5 or 10 min.) to obtain a conclusive interferometer lobe pattern, and although it appeared likely that these signals might be of Venusian origin some independent type of observation was needed to make the identification more definite. This came about from a study of the magnetic sound tapes, on which the audio output of the receiver had been recorded; when it was noted

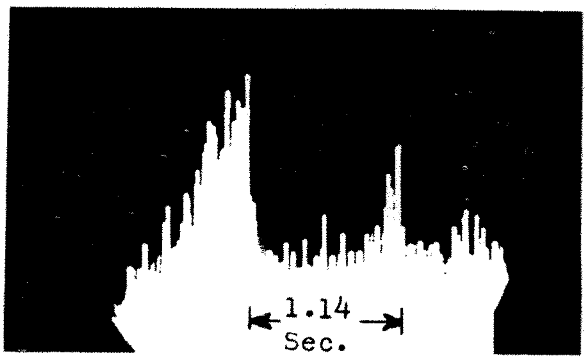

Fig. 2. Class II pulse with echo observed about 1.15 p.m. E.S.T. on June 4, 1956. Time increases to the right, the echo being the smaller peak to the right of the main one

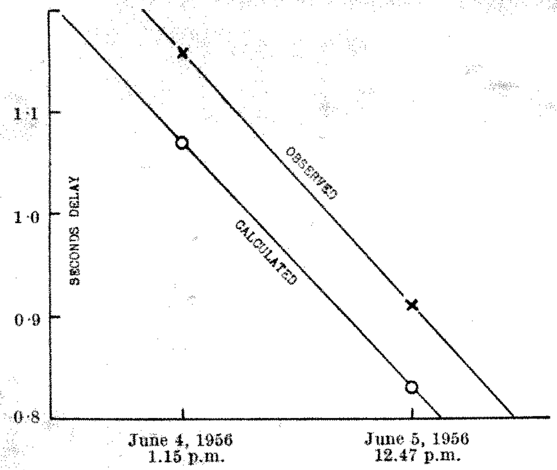

Fig. 3. Comparison of observed and calculated moon echo delay times

that on rare occasions a pulse was followed by a weaker one which sounded like an echo. Two such pulses with echoes were noted on the sound tape for June 4, 1956, occurring within a few minutes of each other about 1.15 p.m. E.S.T. One of the pulses with echo is shown in Fig. 2 as photographed on a cathode-ray oscillograph. This pulse echo has a measured delay time of 1·14 sec. The other pulse echo delay was 1·18 sec., giving an average of 1·16 sec. The Moon was above the horizon at the time and the calculated delay time for a signal reaching the Earth from Venus through a Moon reflexion with respect to a signal reaching the Earth directly from Venus was about 8 per cent less. A search for more pulses with echoes revealed a single one on the sound tape of June 5, 1956, at 12.47 p.m. E.S.T. This one had a measured delay of 0·91 sec. The calculated delay was 0·83 sec., the movement of the Moon causing a reduction in the echo delay time of 0·24 sec. (1·07–0·83) between the times of observation on June 4 and 5. It is highly significant that the observed delay time changed by 0·25 sec. (1·16–0·91) or by nearly the same amount. The results are compared in Fig. 3.

There appears to be a consistent difference between the observed and calculated delay times on the two days due to a relatively constant experimental effect, but the change in both observed and calculated times is very nearly equal. The probability of this being a coincidence or due to some other cause is very small, so that it appears that the pulses are of Venusian origin. A lower signal velocity than for waves in empty space could account for the difference between the observed and calculated values, but any such reduction in velocity would probably be sufficiently small to account for only a portion of the difference.

To receive a Moon echo of the strength observed requires about fifty decibels more echo-power than the Moon would provide as a uniform spherical scatterer of radio waves. Nevertheless, such enhancement could occur if a relatively large flat area of the Moon were properly oriented so as to give a direct reflexion to the Earth. In fact, if the surface in question were slightly concave (as a shallow valley) and of approximately parabolic contour, with the Earth at the focus, very large increases in power of echo could be expected. However, the proper orientation of the Moon to obtain such a reflexion would be a rather rare occurrence, which would account for the fact that echoes are seldom observed.

I am indebted to Dr. H. C. Ko for making independent calculations of the echo delay times.

Diffraction of Light by Ultrasonic Waves at 300 Mc./s.

THE highest frequency so far adopted for the study of diffraction of light by ultrasonic waves is 180 Mc./s. reported by Bhagavantam and Rao[1]. Diffraction patterns at these frequencies were found to show some unusual and interesting features which were studied in detail by these authors.

Using an *RCA* 826 valve in a parallel line oscillator circuit and a *z*-cut precious red tourmaline crystal 0·6 mm. thick, we have recently been able to push up this frequency to nearly 300 Mc./s. and study the diffraction effects due to progressive waves set up in water. Diffraction patterns could be observed at all frequencies up to 300 Mc./s. by exciting the crystal at one of its odd harmonics. In order to measure dispersion, if any, of ultrasonic velocity in water, the crystal has been excited at the highest frequency and another lower frequency and the diffraction patterns photographed on the same plate at about the same time using a camera of 21-cm. focal-length. Fig. 1 shows the patterns at the two frequencies of 50·34 and 297·03 Mc./s. photographed at the Bragg angle of incidence for the higher frequency, using the mercury green line as the source of light.

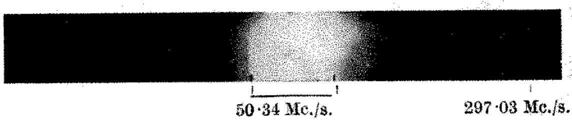

Fig. 1

Results for the velocity of sound waves measured at the two different frequencies are given in the accompanying table along with the fringe-width and the order of the harmonic of the crystal which was excited. The lower frequency was measured accurately by a Marconi precision heterodyne wave-meter while the highest frequency was measured by using a Lecher-wire set up.

In view of the appreciable angle of diffraction (6° 10′) at the higher frequency, it is not possible to approximate sin θ to tan θ and take the fringe-width as proportional to the frequency as is usually done in the lower frequency-range. The velocity at 300 Mc./s. is calculated by evaluating sin θ from the value of d/D. The sound beam at 300 Mc./s. is confined close to the surface of the crystal due to heavy absorption, and as the liquid in contact with the crystal is sub-

Table 1. FOCAL LENGTH OF THE CAMERA $D = 21$ CM.

Order of harmonic	Frequency ν^* (megacycles per sec.)	Fringe-width d (cm.)	$\frac{\nu^*}{d}$	Velocity (m. per sec.)	Temp. (° C.)
9	50·34	0·3844	130·6	1,502	24·8
53	297·03	2·2744	130·9	1,508	27·0

ject to heavy radio-frequency heating the average temperature of the liquid could not be determined quite accurately. Considering the uncertainty in the measurement of this temperature, the results may be taken to indicate that there is no dispersion of ultrasonic velocity in water up to 300 Mc./s. The values for the velocity are in fairly good agreement with those reported by other investigators. The wave-length of sound in water corresponding to 297·03 Mc./s. employed in this investigation is 0·000503 cm., which is only about twelve times the wave-length of mercury green light in water.

The general features of the diffraction pattern at 300 Mc./s. are similar to those at 180 Mc./s. reported earlier. The sharpness of the appearance of the diffraction line around the Bragg angle of incidence is, however, more prominent at the higher frequency. Quantitative study of the variation of intensity of the diffraction pattern with angle of incidence and width of the sound field is in progress and the results will be reported in due course.

Calibration of Vibration Pick-ups at High Frequencies using a Michelson Interferometer

MOST existing methods of calibrating vibration pick-ups employ some form of extrapolation, that is, the pick-up is calibrated at low frequencies, where the amplitude can be made large, and the result is then extended to higher frequencies. Since it is considered that this method is unsatisfactory, a Michelson interferometer capable of measuring vibratory amplitudes down to 4 × 10^{-6} in. has been constructed. The upper limit of the calibration frequency is largely determined by the type of vibration pick-up and by the driving vibrator, but the present arrangement can be used up to 10 kc./s.

The Michelson interferometer takes its usual form except that it is mounted in a vertical plane for convenience. One of the two mutually perpendicular mirrors is attached to a block on the vibrator armature and the vibration pick-up is fixed to the same block. Using monochromatic light (in this case the green line of mercury at 5461 A.), circular fringes are set up in the usual manner. As the vibration amplitude is slowly increased, the fringes alternately disappear and reappear. The disappearance, that is, when the field of view is apparently uniformly illuminated, is quite sharp and each disappearance corresponds to a definite amplitude of vibration of the moving mirror, and Ostberg (1932) has calculated these amplitudes. Provided the vibration wave-form is a pure sinusoid, these amplitudes are determined by a Bessel function of order zero and the first three values are approximately 4·1, 9·4 and 14·8 millionths of an inch for a light wave-length of 5461 A.

Preliminary experiments have shown that this apparatus can be used for calibrating a barium titanate accelerometer over a frequency-range of 500 c./s. to 10 kc./s. It can also be used for proving that the output of the accelerometer at a given frequency is proportional to the amplitude of vibration, that is, to the acceleration.

Inadequacy of Recombination as the Source of Light from Enduring Meteor Trains

IT has been suggested[1,2] that the enduring column of light left by a meteor in its passage across the sky is produced by radiative recombination of the meteoric ions and free electrons. We wish to criticize this hypothesis on a quantitative basis.

Consider a line of q ion pairs per cm. which diffuse with an ambipolar diffusion coefficient D cm.^{2}/sec. to form a column with a Gaussian cross-section.

Let α_e be the recombination coefficient of the ions and electrons and p be the luminous energy emitted per recombination event between wave-lengths 4680 A. and 5560 A. The luminous energy, I, emitted per cm. of train per second is then given by the equation

$$I = \frac{p\,\alpha_e\,q^2}{8\pi D t} \qquad (1)$$

where t is the time that has elapsed since the passage of the meteor.

Let us consider a Perseid and a Geminid meteor with absolute visual magnitudes − 2·0 and − 3·0 respectively. The work of various authors enables us to compute the brightness of the train from equation (1).

(i) Öpik[2] has computed the visual intensities from the cascade spectra for recombination of the ions that are to be expected in meteor columns; he finds that the most efficient reaction is Fe II (a^4p) + e → Fe I, where $p = 1{\cdot}51 \times 10^{-12}$ ergs. Öpik computed the recombination coefficient for this reaction and for recombination events involving other atoms. After correction to a temperature of 212° K., we may adopt $\alpha_e = 2{\cdot}6 \times 10^{-12}$ cm.^{3} sec.$^{-1}$.

(ii) From the duration of radio echoes observed by Millman[1], we may deduce[3] that for a Perseid meteor of visual absolute magnitude − 2·0, $q = 1{\cdot}25 \times 10^{15}$ ion pairs per cm., and for a Geminid of absolute magnitude − 3·0, $q = 1{\cdot}43 \times 10^{14}$ cm.$^{-1}$.

(iii) Millman[1] has given the mean height of Perseids and Geminids of absolute visual magnitude + 0·5 as 102·6 km. and 97·0 km. We may assume that these heights apply to the brighter meteors as well, and compute values of the diffusion coefficient, D, from the results of Greenhow and Neufeld[4].

Substitution of the values of sections (i), (ii) and (iii) and $t = 1{\cdot}0$s. in equation (1) yields the luminosity, I, of a cm. length of meteor train. These values are given in Table 1.

Table 1. LUMINOSITY OF PERSEID AND GEMINID METEOR TRAINS ONE SECOND AFTER FORMATION

	Absolute visual magnitude	I ergs/cm./sec. estimated from recombination	I_0 ergs/cm /sec observed visually
Perseids	−2·0	1·22	400
Geminids	−3·0	3·82	400

Naked-eye observers[1] have recorded the visible duration of trains produced by Perseid and Geminid meteors. We may assume that a line source is on the limit of visibility when it is equivalent to a succession of stars of apparent magnitude + 6·0, all spaced at the limit of angular resolution of the human eye, which is 3·5′ or 0·00102 radians. Thus a train on the limit of visibility, making an angle θ with the line of sight, emits I_0 ergs of visible energy per cm. of length according to the relation

$$I_0 = \frac{4\pi R \cdot F_S \sin\theta}{0{\cdot}00102} \qquad (2)$$

where R cm. is the range of the element of the train and F_S is the flux produced by a star of 6th magnitude between wave-lengths of 4680 A. and 5560 A. For an unreddened star of apparent photo-visual magnitude[4] + 6·0 and spectral type *AO V*, the formula of Cook and Millman[5] and the tables of Milford give:

$$F_S = 1{\cdot}52 \times 10^{-8} \text{ ergs cm.}^{-2} \text{ sec.}^{-1} \qquad (3)$$

If the observer's field of attention, of approximate diameter 0·4 radian, is centred on the radiant, then the mean value of sin θ for a large number of trains is 0·138.

In the radio-visual correlations described by Millman the mean range R of the trails was 155 km., which we adopt for the trains. From the train observations we may deduce that for − 1·0 magnitude Perseids and − 2·0 magnitude Geminids the trains were at the limit of visibility 1 sec. after the passage of the meteor. The observed luminosity from equation (2) is included in Table 1.

A comparison shows that the meteor train is about two hundred times brighter than we would expect from ionic recombination. We are led, therefore, to postulate an alternative method for storing energy and producing visible radiation. A possible method is the formation of active nitrogen which afterwards excites neutral meteor atoms in the trail[6]. This mechanism is being studied further at the time of writing, and the results will be published elsewhere.

Effect of Drawing on the Infra-red Dichroism of Nylon-66 Filaments

We wish to report on studies made of the polarized infra-red spectra of variously drawn nylon-66 filaments, where it has been found that the method used for specimen preparation may have an important influence on the experimental results. The optics of the 0·78 N.A. reflecting microscope used, in connexion with a Perkin–Elmer Model 12-*C* infra-red spectrometer, were identical with those mentioned by Quynn and Steele[1]. A set of silver chloride sheets was used for obtaining polarized radiation.

A series of nylon-66 filaments, prepared by melt spinning and ranging in draw ratio from one (undrawn) to four, was kindly supplied by E. I. du Pont de Nemours and Co. The undrawn filaments had a diameter of about 120 microns, which decreased with drawing to about 65 microns at draw ratio four, or at each draw ratio the filaments were approximately twice the diameter of those used by Quynn and Steele[1]. Specimens of approximately 4–6 microns in thickness were found suitable for infra-red examination, and these were prepared by microtoming.

It is possible to obtain desirably thin specimens by mechanical flattening of single filaments as well as by longitudinal sectioning with a microtome. But we have found that the flattening process can induce orientation in a filament and that this effect is accentuated when the filament is of initially low orientation. Such induced orientation may be greatly reduced when longitudinal sections are prepared by microtoming filaments embedded in a plastic. The embedding medium used in our work was plasticized polymethylmethacrylate. Three different methods of specimen preparation were used: (*a*) microtoming of previously flattened samples with the direction of blade motion parallel to the filament axis, (*b*) microtoming undeformed samples in a direction perpendicular to the filament axis, and (*c*) microtoming undeformed samples in a direction parallel to the filament axis.

Another problem associated with microspectroscopic examination of fibres in the infra-red region is that of delusive energy or 'stray light'. When only the nylon filament is located at the specimen stage of the reflecting microscope, it is found that a significant portion of the energy transmitted to the thermocouple of the spectrometer is energy which has gone around the edges of the filament and has become part of the filament image at the entrance slit of the monochrometer. In our experiments the 'stray light' was masked out at the specimen stage by placing pieces of thin aluminium foil, with slits 30–70 microns wide, over the longitudinal sections of filaments.

In calculations of the dichroic ratios shown in Table 1, allowance has been made for the reduction of energy caused by scattering at the sample, but no correction has been made for the effect of beam convergence in the reflecting microscope. It may be shown, using an analysis of the type described by Fraser[2], that the latter effect is a small one. Generally, the mean values shown in Table 1 are for measurements made on 5–14 filaments. In the cases

Table 1. Dichroic Ratio $(\epsilon\pi/\epsilon\sigma)$ Values for Nylon-66 Filaments

cm.$^{-1}$	Draw ratio			
	1·0	2·0	3·0	4·0
(*a*) Microtoming previously flattened samples in direction parallel to filament axis				
3,310	2·39	0·88	0·79	—
3,080	2·35	0·90	0·78	—
2,925	1·37	0·94	0·90	—
2,360	1·58	0·92	0·89	—
(*b*) Microtoming in direction perpendicular to filament axis				
3,310	1·18	0·81	0·56	0·50
3,080	1·14	0·77	0·61	0·54
2,925	1·03	0·68	0·63	0·56
2,860	1·06	0·81	0·68	0·66
(*c*) Microtoming in direction parallel to filament axis				
3,310	0·78	0·72	0·54	0·55
3,080	0·78	0·67	0·52	0·45
2,925	0·93	0·73	0·70	0·68
2,860	0·85	0·78	0·70	0·65

of part (a) of Table 1 at draw ratio three and of parts (b) and (c) at draw ratio four, however, only two filaments were studied.

When appropriate statistical consideration is given the results, it is observed that the effect of specimen preparation is greatest at draw ratio one and becomes ess important at the higher draw ratios. Flattening nduces considerable parallel dichroism of all the four absorption bands at draw ratio one, and this effect is much greater than that caused by microtoming plastic-embedded filaments in a direction perpendicular to the filament axis. Some perpendicular dichroism appears to be induced at draw ratio one when the microtoming is done in a direction parallel to the ilament axis.

The dichroic behaviour of the 3,310 cm.$^{-1}$ band N—H stretching) is identical with that of the 3,080 cm.$^{-1}$ band (presumably N—H stretching). The two methylene-group stretching motions at 2,925 and 2,860 cm.$^{-1}$ exhibit nearly the same dichroic behaviour, and the extent of their dichroism is generally less han that of the two N—H stretching motions. With hese filaments, there is no reversal of dichroic character in going from draw ratio two to higher draw ratios, as was observed by Quynn and Steele[1]. The results suggest a random arrangement of nylon polymer chains at draw ratio one, with increasing drawing causing increasing alignment of these chains with respect to the filament axis.

The results of X-ray diffraction studies carried out on these filaments are consistent with those of the infra-red measurements. It is suggested that the parallel dichroism found for the four nylon absorption bands at the lower draw ratios by Quynn and Steele[1] was caused by the mechanical flattening procedure they used to obtain suitably thin specimens.

The experiments discussed here will be reported in greater detail elsewhere.

Biological Research in East Africa

In the account, entitled "Zoonoses in East Africa", of the conference held earlier this year in Kampala by the East African Medical Research Scientific Advisory Committee (see *Nature*, March 3, p. 406), it is stated (p. 407, col. 1) that "it is regrettable that in East Africa so little collecting is being done". Contrary to this statement, the Coryndon Museum, Nairobi, has hundreds of thousands of specimens and eceives two thousand specimens monthly. A few ines further on, the article says, "it is difficult to get birds, mammals or insect identifications done in East Africa". Again, contrary to this statement, the Coryndon Museum, Nairobi, under Dr. L. S. B. Leakey, the curator, can do all this and, more to the point, has type specimens.

For birds, the Coryndon Museum has a first-class rnithologist and the finest collection of East African birds anywhere. We have now the two volumes of "The Birds of Kenya" by Mackworth-Praed and Grant. The Museum has a very fine and extensive ollection of insects and a first-class entomologist, while the small mammals are rapidly being built up under the mammologist. The same applies to snakes. The Botany Section is just as good, while the Palæontological and Archæological Sections are known all over the world. Again, the Fish Division of the Kenya Game Department has a very great knowledge covering the past twenty years on these matters and has published a great deal of it. The Jinja Fisheries Research Station has begun publication of "The Fresh Water Fishes of Uganda", and Kenya also has ready the manuscript for a like book on the fresh-water fishes of the Colony. With reference to the marine fishes, this is the work of Prof. J. L. B. Smith, and shortly to appear is a publication covering marine fisheries of Kenya. The Natural History Society of Kenya has published a report on the "Fauna of Tanganyika"; and its volumes are full of such papers. This brief list shows that the information exists, and work is being done.

The need for faunal surveys in the Colonies has been realized for at least the past twenty years; but we have never had the money, and unless this is forthcoming, these surveys cannot be undertaken. We work in co-operation with the British Museum and with their specialists, and rightly so; and get much help from them. However, the crux of the matter is that there is no co-ordination between the various services in East Africa and the scientific workers there. This lack is proved by the article describing the conference. It is one of the most serious problems in East Africa. Scientific officers work in isolated places, cut off from associates both in a Colony and with men working on the parallel problems in other Colonies. There is no free exchange, either oral or written, of work being done or even written reports of work being done, and although heads of scientific and development departments realize this, yet very little has been done to make things easier. I speak from many years experience of Africa.

HUGH COPLEY

Game Department,
P.O. Box 241,
Nairobi.
April 10.

No one would wish to fail to acknowledge the work being done at the Coryndon Museum: the difficulties under which the Museum labours are brought out by Mr. Copley in his final paragraph. Formal surveys of the type asked for have not, in fact, been possible. They were called for at the Kampala conference by East African biologists. It was these same East African biologists who spoke of the difficulties they encounter in getting birds, mammals and insects identified. It is perhaps significant that the more confident note was struck by a visiting American speaker; but he was referring to the British Museum. All concerned in biological and medical work in East Africa would be happy to see the staff of the Coryndon Museum in a position to afford the services so urgently called for. The organization of the conference was itself an effort to overcome the isolation and lack of contact which Mr. Copley mentions.

J. N. P. DAVIES

P.O. Box 2072,
Kampala.

FORTHCOMING EVENTS

Wednesday, July 25

Society for the Promotion of Nature Reserves (in the Lecture Room, British Museum (Natural History), London, S.W.7), at 4 p.m.—Lieut.-Colonel J. Vincent: "Game Reserves of Natal"; also colour film, "Zululand Sanctuary".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p m.—Discussion Meeting—"Visit of the Royal Society Delegation to the U.S.S.R". Chairman · Prof. A. V. Hill, F.R.S. Speakers: Dr. Mary L. Cartwright, F.R.S., Dr. H. G. Thornton, F.R.S., and Dr. D. C. Martin, F.R.S.E.

Thursday, July 26

Royal Society of Tropical Medicine and Hygiene (at the Hospital for Tropical Diseases, 4 St. Pancras Way, London, N.W.1), at 7.30 p.m.—Clinical Meeting.

Thursday, July 26—Saturday, July 28

Royal Meteorological Society (at the Pantycelyn Hall of Residence of the University College of Wales, Aberystwyth)—Meeting in honour of Sir David Brunt, Sc.D., F.R.S.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Agronomist (with a university degree in agriculture) to assist in field experiments dealing with grassland and arable crops—The Secretary, The Grassland Research Institute, Hurley, Maidenhead, Berks (July 28).

Director (scientist of established reputation under 60, with outstanding research work to his credit, and administrative experience) of the Indian Association for the Cultivation of Science—The Registrar, Indian Association for the Cultivation of Science, Jadavpur, Calcutta 32, India (July 28).

Research Assistants (with good honours degrees) for research in the following fields. heterogeneous catalysis; corrosion reactions; plastics materials; organic synthesis; physics; or electronics—The Registrar, College of Technology, Suffolk Street, Birmingham (July 28).

Physicist (with an honours degree in physics) for work on the clinical applications of radioactive isotopes—The Registrar, The University, Leeds 2 (July 30).

Assistant Lecturer (with special qualifications or interests in radio astronomy) in Physics—The Registrar, The University, Manchester 13 (July 31).

Director (with an intimate knowledge (preferably with actual experience) of tsetse fly control operations, and sound scientific knowledge of the ecology and biology of the tsetse fly, together with proved administrative ability of a high order) of the Department of Tsetse and Trypanosomiasis Control and Reclamation, Federal Ministry of Agriculture, Federation of Rhodesia and Nyasaland—The Public Service Attaché, Rhodesia House, 429 Strand, London, W.C.2 (July 31).

Demonstrator (with an honours degree in chemistry or biochemistry) in the Department of Chemistry and Biochemistry—The Dean, St. Thomas's Hospital Medical School, London, S.E.1 (August 1).

Assistant (with an honours degree in botany, preferably with postgraduate experience in plant pathology) in the Advisory Plant Pathology Department—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8 (August 10).

Lecturers (3) (with a degree or equivalent qualification) in Crop Production; and a Lecturer (with a degree or equivalent qualification) in Animal Production, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 16).

Chair of Botany at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 31)

Chair of Mineralogy and Geology at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31)

Lecturer (with an interest and experience in biophysics) in Physiology—The Secretary, The University, Aberdeen (August 31).

Senior Lecturer (graduate from a recognized university school of mines, with the minimum qualification of bachelor's degree in mining engineering or equivalent, wide experience in the practice of mining, and preferably experience in lecturing) in Mining Engineering at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 31).

Reader in Applied Thermodynamics in the University, and Head of the Department of Mechanical Engineering, in Robert Gordon's Technical College—The Secretary, The University, Aberdeen (September 25).

Reader in Pure or Applied Mathematics—The Secretary of Faculties, University Registry, Oxford (October 31).

Experimental and Assistant Experimental Officer (preferably with experience with transient oscillography or vacuum techniques, and at least H.S.C. (science) or equivalent), for interesting work on problems involving high energy electrical discharges through gases over a wide range of pressures—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. B.795/34.

Extraction Metallurgist or Chemist (preferably with a physicochemical background and some industrial experience), for research and development on treatment of slags—Dr. F. D. Richardson, Nuffield Research Group, Royal School of Mines, London, S.W.7.

Lecturer or Assistant Lecturer in Physical Chemistry—The Registrar, The University, Nottingham.

Lecturer (with research interests in either inorganic or physic chemistry) in Inorganic Chemistry—Northern Polytechn Holloway, London, N.7.

Librarian (qualified male librarian with experience of technic libraries)—The Secretary, The Institution of Mining Engineer 3 Grosvenor Crescent, London, S.W.1.

Medical Laboratory Technician (with either A.I.M.L.T. or B.Sc in the Research Department—The Group Secretary, c/o Gener Hospital, Sunderland.

Physicist (male, with a good honours degree or A.Inst.P), f research on servo-control mechanisms—The Wool Industries Researc Association, Torridon, Headingley, Leeds.

Professor of Anthropology and Sociology at the College o Arts and Sciences, Baghdad, Iraq—The Cultural Attaché, Roya Iraqi Embassy, 22 Queen's Gate, London, S W.7.

Senior Lecturer in Electrical Engineering; a Lecture in Electrical Engineering; and an Assistant, Grade B, to teac mathematics up to higher National Diploma standard—The Registra Hatfield Technical College, Hatfield, Herts.

Senior Lecturer in Physics to teach up to B.Sc. (Special) Degre standard and to share in the postgraduate work of the Department—Northern Polytechnic, Holloway Road, London, N.7.

PERMUTIT

ION EXCHANGE MATERIALS

The use of Permutit Ion Exchange Materials in many roles distinct from water treatment, has resulted in the development of numerous new industrial processes giving improved results and lower running costs. Some materials now available are :—

Zeo-Karb Na. A sulphonated coal product containing both strong and weak acid groups.

Zeo-Karb 215. A nuclear sulphonated phenol resin containing also hydroxyl groups.

Zeo-Karb 225. A unifunctional cross linked sulphonated polystyrene resin in bead form of high capacity and exceptional chemical and physical stability.

Zeo-Karb 226. A unifunctional cross linked methacrylic acid resin in bead form containing only carboxyl groups as the ion active groups.

De-Acidite E. A high capacity anion exchange material of medium basicity.

De-Acidite FF. A unifunctional very highly basic anion exchange resin in bead form based on cross linked polystyrene and containing quaternary ammonium groups.

De-Acidite G. A unifunctional weakly basic anion exchange resin in bead form based on cross linked polystyrene and containing diethylamino groups.

De-Acidite H. A material similar to "De-Acidite G" but containing dimethylamino groups.

Bio-Deminrolit. A mixed cation and anion exchange resin for demineralisation in a single column.

Decalso F. A synthetic sodium aluminium silicate suitable for the separation and concentration of vitamins and hormones.

Decolorite-Asmit. A resin of high porosity for removing colour from solutions.

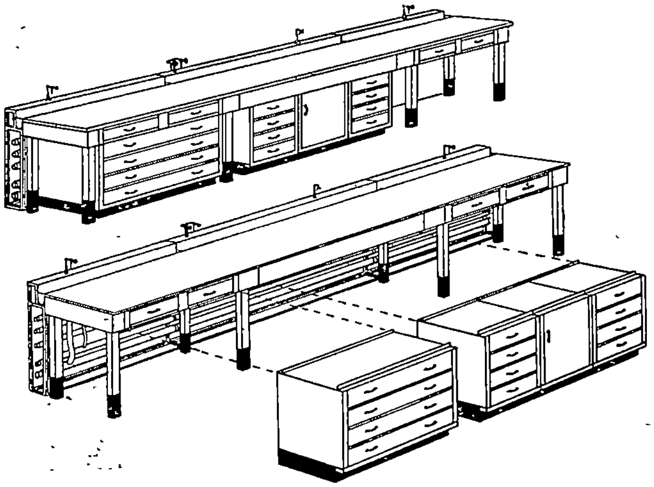
Permaplex C-10. A highly selective cation exchange resin membrane containing SO_3H groups.

Permaplex A-10. A highly selective anion exchange resin membrane containing quaternary ammonium groups.

For full technical information please write to: THE PERMUTIT COMPANY LIMITED. Head Office and Laboratories: Dept. V.H.92, Permutit House, Gunnersbury Avenue, London, W.4. Telephone: CHIswick 6431

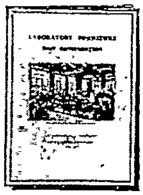
Permutit Ion Exchange Materials — Made in Britain by British Labour

a NEW range of LABORATORY METAL FURNITURE



AND PREFABRICATED SERVICE RACKS

The *flexibility*, *economy* and *general usefulness* of *UNIT* furniture are advantages which cannot be disregarded.
We offer standard benches of modern design and construction, with removable units, in metal; and standard service racks which will connect up to supplies (electricity, gas, water, steam, etc.) provided at any *one* point in the Laboratory. May we tell you more about them ?



Illustrated Brochure Free on Request.

LECTURES AND COURSES

UNIVERSITY OF BRISTOL

DIPLOMA IN HORTICULTURAL SCIENCE
DIPLOMA IN PLANT PATHOLOGY AND PROTECTION

The above postgraduate Diploma Courses will be available during the session 1956-57. Conducted in part at the Long Ashton Research Station, they are intended primarily for those with good honours degrees in science who seek careers in horticultural research at home or overseas

The Horticultural Science course commences on September 10, the Plant Pathology course on October 1. Both extend over a full session of three terms, ending in June or July, and include some additional practical work during the vacations.

Early application should be made to the Registrar, from whom full particulars may be obtained.

CHELSEA POLYTECHNIC

MANRESA ROAD, S W.3
(Telephone: FLAxman 5747)

Full-time courses and part-time day and evening courses are arranged in Biology, Botany, Chemistry, Geology, Mathematics, Physics, Physiology, Zoology, in preparation for the preliminary (intermediate) science examination and the B Sc. general degree of the University of London for internal and external students, and for professional examinations.

Courses are also held for the B.Sc. internal special or honours degrees in Botany, Chemistry (full-time only), Geology, Mathematics, Pharmacy, Physics, Physiology (evening only) and Zoology.

Facilities are available for research and postgraduate study and short courses of lectures are held on special topics.

Full-time courses are arranged for professional qualifications in Pharmacy and Chiropody. There are special evening courses in Food and Drugs, Gemmology, Industrial Microbiology, and Surgical Technicians' work.

Applications for enrolment for the Session 1956-57 may now be made on forms to be obtained from the Principal.

OFFICIAL APPOINTMENTS

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL

Applications are invited for the post of Demonstrator in the Department of Chemistry and Biochemistry. Candidates should hold an honours degree in chemistry or biochemistry and should be prepared to engage in research in biochemistry with a view to obtaining a higher degree in this subject. Salary £450 per annum.

Applications, giving details of qualifications and the names of two referees, should be sent before August 1, 1956, to the Dean, St. Thomas's Hospital Medical School, London, S.E 1, from whom further information may be obtained.

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF CHEMISTRY

Applications are invited for the appointment of a Lecturer or Assistant Lecturer in Physical Chemistry, appointment to date from October 1, 1956. Salary scales: Lecturer, immediate appointment in the range £650 to £1,050, with possible advancement to £1,350 per annum; Assistant Lecturer, £550 to £650 per annum. Superannuation and family allowance.

Conditions of appointment and form of application from Mr. H. Pickbourne, Registrar.

SCUNTHORPE HOSPITAL MANAGEMENT COMMITTEE

LINCOLNSHIRE RADIOTHERAPY CENTRE
(50 beds)
MEDICAL PHYSICIST

Immediate vacancy in the expanding department including developments connected with rotational therapy and radioactive isotopes—previous experience desirable but not essential. Probationary period of two years for new entrants to Health Service. Salary scale (first- or second-class honours) £525 by £25 to £625—others £475 by £25 to £575. Scale after probationary period £650 by £30(3) by £35(3) to £845 Postgraduate experience considered in fixing entry point. Superannuation scheme.

Application forms from Group Secretary, War Memorial Hospital, Scunthorpe.

UNIVERSITY OF ABERDEEN

Applications are invited for the post of Lecturer in Physiology. Candidates should have interest and experience in biophysics. Salary, scale (c), £1,750 to £2,050 if medically qualified, otherwise £1,350 to £1,550; or scale (b) £1,200 to £1,700 if medically qualified, otherwise £950 to £1,350. Placing on scale according to qualification and experience. Superannuation (F.S.S U.) and children's allowance. Part of removal expenses refunded.

Conditions of appointment and forms of application should be obtained from the Secretary, The University, Aberdeen; with whom applications (8 copies), giving the names of three referees, should be lodged not later than August 31, 1956. Applicants outside the British Isles may submit one copy only.

UNIVERSITY OF DURHAM

KING'S COLLEGE, NEWCASTLE-UPON-TYNE

Applications are invited for the following Research Assistantships in the Department of Physics commencing October 1, 1956 1. Senior Assistant to help in design and supervision of the electronic controls of a high precision mass spectrometer now being built. Preference given to a graduate in electrical engineering 2 Senior Assistant to work on the ferromagnetic aspects of rock magnetism. Preference given to a graduate in physics with some research experience. 3. Assistant to work on palaeomagnetism, concerned mainly with operating an astatic magnetometer. Minimum qualification a pass degree in physics. Appointments are for three years in the first instance, with salary scales of £600 to £700 plus F.S S.U. contributions for the first two positions and £450 to £600 for the third.

Further particulars may be obtained from the undersigned, to whom applications should be addressed not later than July 31, 1956

G. R. HANSON
Registrar of King's College.

REGIONAL RADIUM INSTITUTE

BRADFORD

Assistant Physicist (Basic Grade) required for duties in the above Radiotherapy Centre. The position offers wide experience in hospital physics Previous hospital experience not essential Salary in accordance with Whitley Council Scales.

Applications, stating age, qualifications and experience, together with the names of two referees, to the Secretary, Royal Infirmary, Bradford.

HILL FARMING RESEARCH ORGANIZATION

Applications are invited from honours graduates in botany or agricultural botany for appointment as Scientific Officer on the staff of the Organization's Department of Botany. The appropriate salary scale will be £458 to £835 per annum (male), plus pay supplement of £69 to £118 per annum, according to placing on salary scale. The post will be superannuable under F S S.U.

Applications, which should include the names and addresses of two referees and should be accompanied by copies of two recent testimonials, should be submitted, not later than August 4, 1956, to the Secretary, Hill Farming Research Organization, 48 Palmerston Place, Edinburgh, 12, from whom further particulars may be obtained

MENTAL HEALTH RESEARCH FUND FELLOWSHIP

Applications are invited for Mental Health Research Fund Fellowships from suitably qualified persons wishing to pursue full-time research work bearing on problems of mental health, whether in clinical psychiatry or in one of its supporting sciences. Both senior and junior fellowships are offered in the salary ranges of £700 to £1,200 and £1,300 and £2,000 (inclusive of superannuation). The appointments will be for up to three years in the first instance.

Further information from the Secretary, Mental Health Research Fund, 43 Queen Anne Street, W.1.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Assistant Lecturer in Physics with special qualifications or interests in Radio Astronomy Salary scale £550 to £650 per annum, with membership of the F.S S U and children's allowance scheme.

Applications should be sent not later than July 31, 1956, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained.

COMMONWEALTH of AUSTRAL

DEPARTMENT OF SUPPLY
PROTECTIVE CHEMISTRY DIVISION
DEFENCE STANDARDS LABORATORIE
MARIBYRNONG, VICTORIA

Applications are invited for a temporary p tion of Scientific Officer, Grade 1, at the ab Laboratories. Salary: £A.1,263 to £A 1,578 annum. Duties. Research on the spectrosc of the solid state, with particular reference soft X-ray spectroscopy of metals and all Qualifications: Degree of high standard physics as a major subject. Whilst the posit is a temporary one, the tenure of employmen not limited. However, the successful applic may choose to enter into an agreement fo three- to five-year contract of employment Australia In this case, the Commonwealth bear cost of return fares, together with cost removing each way the appointee's furniture effects up to a maximum cost of £A.500, £A each way. Under specified conditions, first-c boat fare (if first class berth available) for appointee and dependants (wife and depend children) will be paid by the Commonwealth.

Application forms obtainable from Se Representative (AP.50), Department of Sup Australia House, Strand, London, W C.2, whom applications should be lodged by July 1956.

UNIVERSITY OF MALAYA

SINGAPORE

Applications are invited for appointment to first Chair of Agriculture Salary in range £2, to £2,548 according to qualifications and expence Allowances expatriation £378 per ann cost of living in range £210 to £560 per ann All paid in Malayan currency. Passages for pointee, wife and children under 12 years P. furnished quarters at reasonable rent. Provid fund scheme.

Applications (six copies), naming three refer and detailing qualifications and experience, September 30, 1956, to Secretary, Inter-Univer Council for Higher Education Overseas, Woburn Square, London, W.C.1, from wh further particulars may be obtained.

UNIVERSITY OF LEEDS

RESEARCH FELLOWSHIP

Applications are invited from chemists or chemists with research experience in protein polysaccharide chemistry for an appointment Research Fellow to work in collaboration Dr. D. A Hall, of the Nuffield Gerontolog Unit in the Department of Medicine. The Fel will be expected to assist in the research p gramme of the Unit, which is concerned ageing and with the inter-relationships of structural components of connective tissue. initial salary would be in the range £700 to £ and the appointment would be in accordance the normal conditions appertaining to Univer appointments.

Applications should reach the Registrar, University, Leeds, 2, not later than July 27, 1

UNIVERSITY OF WESTERN AUSTRALIA

The Senate of the University of West Australia has decided to establish a Chair Mechanical Engineering, and applications are vited for this position. The salary of the Pro sor will be £A.3,000 per annum, and an all ance is made towards travelling expenses.

Further particulars and information as to method of application may be obtained from Secretary, Association of Universities of British Commonwealth, 36 Gordon Square, L don, W C.1. The closing date for the rec of applications in Australia and London, September 29, 1956.

UNIVERSITY OF THE WITWATERSRAND

JOHANNESBURG, SOUTH AFRICA

Applications are invited for appointment t post of Lecturer on the staff of the Departm of Physics Duties are to be assumed on Ja ary 1, 1957, or as soon as possible therea Preference will be given to a candidate with search interests and experience in the physics solids. The substantive salary scale attached the post is £850 by £50 to £1,150 In additio married man will receive a temporary cost living allowance at the rate of £234 per annu

Applicants are advised to obtain a copy of information sheet relating to the above vaca from the Secretary, Association of Universi of the British Commonwealth; 36 Gordon Squ London, W.C.1. Applications close on Septem 1, 1956.

CHEMICAL LABORATORY SCIENCE COLLEGE Date 10.9.56

A NEW OUTLOOK ON COAL

ON p. 171 of this issue is given a summary of the recent report issued by the Organization for uropean Economic Co-operation (O.E.E.C.) entitled Europe's Growing Needs of Energy : How can they e Met ?" The report gives a detailed review of the nergy supplies and requirements of the twelve uropean nations that support the Organization. It is he work of a Commission of Experts who have gone o great pains to consult the pertinent authorities that ay be able to give a realistic view of the probable equirements of the future. The resultant estimates rovide an attractive picture of the possible future rowth in productivity and the standards of living Western Europe as a whole, provided no abnormal vents such as wars or economic upheavals intervene. t the same time, the Commission raises some useful arning signals as to the magnitude of the gap etween the probable production of energy and the equirements associated with an expanding world conomy. Many of these caveats apply particularly o the position of Great Britain, in regard to which he gaps between supply and consumption already ring a strain upon the national economy. Examination of the graphs provided in the report shows he prospect of more serious gaps between production nd consumption developing at an increased rate etween 1956 and 1975, which can only be met by nports of coal and oil.

The primary energy requirements of Western urope by the target year of 1975 are likely to mount to 1,200 million equivalent tons of coal ; but he primary energy production, represented by coal, ndigenous oil, natural gas and nuclear fuels is likely o amount to only 750 million tons. If this gap is o be bridged entirely by imports of coal and oil, heir cost in 1975, based on present prices, would mount to some £1,800 million, to be paid for by quivalent exports of manufactured and other goods.

Looking particularly at the position of Great ritain, the energy consumption from various primary ources in 1954 was : solid mineral fuels, 80 per ent ; petroleum, 13 per cent ; hydro-power, 1 per ent.

Great Britain is the largest importer, the largest efiner and the largest consumer of petroleum products in Western Europe. Thanks to the abundance f coal resources and the high level of industrialization, the *per capita* consumption of energy in the Jnited Kingdom is one of the highest in Europe. Nevertheless, the prospects that the gap between the roduction of indigenous fuels and the required consumption are to be met in the twenty years between 956 and 1975 by any other means than imports of ndigenous fuel are small. We have to face the ituation that only one-fifth of the output of the oal industry in Britain in 1947 came from mines hat had been sunk during the preceding thirty ears. The gathering of the fruits of the more recent cceleration in investment must necessarily be delayed, because new mines and major constructions take many years to complete. British potential in hydro-electric development is small, and cannot be expected to cover more than 1 per cent of the present energy requirements. The recognition of this situation has been responsible for the special drive which has been made in the development of the industrial use of nuclear energy.

Such is the position. What are the warnings and the remedies ? The world's reserves of oil for the immediate future, and indeed in the period under review, are likely to be adequate to bridge the gaps envisaged. But what are the economic dangers ? The increase of consumption is based on the maintenance of the competitive position of the member countries in an expanding world economy, and from it stems the raising of their standard of living. The rapid increase in the dependence of Western Europe on imported energy brings in its train the inherent risks of availability of supply and certainty of rising prices for the imported fuels. A competitive position arises as to the demands of each of the member countries, and as to their economical production of raw or manufactured exports, whereby to pay for the imported fuel. The Commission emphasizes the warning and multiplies the exhortations as to the practicable means of limiting such requirements of imported fuels by developing further the indigenous production of all forms of imported energy. It is emphasized that coal will be the mainstay in Western Europe for many years. There has been a tendency to look upon coal as a back number. This situation is dangerous for the above reason. The view that nuclear energy is also 'round the corner' has also been overdone. The Commission is outspoken in its condemnation of a too optimistic attitude in this respect. False impressions as to the practicable contribution of nuclear energy to Western Europe's needs in the next twenty years have been created by the headline publicity given to developments of relatively small importance in this new field, and to the popular enthusiasm aroused by this new form of energy, a sentiment resembling the interest of a child in a new toy, and the inherent wonderment of man in the apparent magical.

Compared with some of the over-statements on fuel and energy policy that have appeared in many published utterances in recent years by would-be authorities, the conclusion of this report may be likened to a healthy fresh wind blowing through the narrow alleys of an overcrowded city on a hot day. Full note should be taken of the caveat that the public should be made to realize the need for a new outlook on coal. Coal is essentially a long-term industry lacking the flexibility of other industries. So far as Britain is concerned, the economic well-being of the country must still for many years depend upon coal. In effect, a shake-up of the public attitude towards research and development in the use of coal is needed. Not only in these directions is an acceleration of interest and activity necessary, but also in the enhancement of the economic and competitive position of coal by improvements in distribution and marketing methods as well as in processing and coal-burning appliances. Finally, the general question of fuel efficiency, in regard to which the industrialist has possibly in recent years been over-exhorted to the point of passivity, is raised as a matter of great importance. Essentially the rate of progress in this field must depend primarily on the provision of the means of technological progress, the advancement of knowledge and of its means of application. The history of past performance in such fields in Britain has shown noteworthy advances. They can only be continued at an enhanced rate if the means in personnel, equipment and encouragement are provided.

PROPERTIES OF MATERIALS FOR ATOMIC ENERGY

Reactor Handbook

Materials—General Properties. Prepared by the United States Atomic Energy Commission. (Selected Reference Material on Atomic Energy.) Pp. xiii+610. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 79*s*.

THIS handbook on materials is part of the general "Reactor Handbook" which has been issued in accordance with the overall programme for the organization and publication of information developed by the United States Atomic Energy Commission. Following the first chapter, in which the functions of reactor materials are described, the handbook attempts to put within one volume a summary of material selected as useful for metallurgists, ceramic technologists and other workers in the field of materials and related topics of reactor technology. No attempt is made to deal with other than solid materials which have been considered for use in reactors. The chapters, arranged alphabetically, deal with aluminium and its alloys, beryllia, beryllium and its alloys, beryllium carbide, bismuth, carbides, cements and concretes, graphite, hydrides, lithium and its alloys, magnesium and its alloys, molybdenum and its alloys, nickel and its alloys, plutonium and its alloys, rare earths, silicon carbide, stainless steel, thorium and its alloys, titanium and its alloys, tungsten, uranium and its alloys, vanadium and its alloys, and zirconium and its alloys. Materials of high cross-section and cobalt-base alloys are separately treated.

The method of presentation is similar throughout. After a general description of reactor application, availability and cost, extraction and purification are briefly dealt with, followed by sections on physical and chemical constants, mechanical properties, melting and casting, forming, fabrication, machining, joining and heat treatment. Corrosion behaviour and metallography are generally briefly treated.

The information presented refers to American practice, and if the handbook is judged from the British point of view omissions are apparent, as, for example, in the development of reactors cooled by carbon dioxide. In the United States this ha received much less attention than in Britain, an thus the potentialities of magnesium as a reacto material have not been developed.

In general, for atomic energy applications, thre main classes of material can be distinguished. First suitable either as fuels or breeders, come uranium thorium and plutonium. Secondly, the high- or low absorption cross-section of materials like boro cadmium, hafnium, beryllia, beryllium, bismuth vanadium and zirconium make them suitable fo specific atomic energy purposes. The third clas contains the materials such as aluminium and stainless steel which have for years been in norma engineering use, and with which no effort on th part of the Atomic Energy Commission is require to determine relevant information. With this clas there has been a greater dependence on existin publications—in particular, data sheets from manufacturers. It is difficult to select in a handbook jus the right and appropriate amount of informatio from a large background of engineering literature For that reason the chapters on such materials a steel and aluminium suffer so much by compariso with the chapters on materials specifically for atomi energy that the handbook would gain if they wer omitted, except to point out, where appropriate, tha certain features make them suitable for particula parts of power circuits.

With the first two classes, in which the materia has been obtained from sources within the atom energy project, the treatment and coverage are complete except where, as a result of security requirements, as with plutonium, the deletions hav seriously affected the value of the information. Wit uranium the information given is restricted becaus of security requirements and also because the dat of preparation is 1952. The all-important techniqu of canning is barely mentioned, even althoug uranium customarily requires protection for use in reactor. A useful collection of equilibrium diagram is reproduced. Much information about thorium i given, although the significance of the impac properties of the metal is not made clear.

Full information, given on beryllia, graphite hydrides, cements and carbides and elements of hig cross-section based on material developed fro Atomic Energy Commission sources, is not readil available elsewhere. Although the effect of attac by liquid metals is not generally treated, its inclusio in the chapter on beryllium makes this more complete. The value of the chapter would have bee greater if, instead of references, selected constitutio diagrams had been given.

The chapter on bismuth is a useful reference whic indicates its possibilities as a fuel-carrying vehicl and liquid-metal coolant.

As a reactor construction material, the potentialitie of vanadium are noted, although the metal is sensitiv to gaseous contamination and embrittlement.

For zirconium, the potentialities, once the metal i free from hafnium, are dealt with fully. Materia containing as little as 50 p.p.m. of nitrogen is noticeably less resistant to corrosion in water than materia containing 10 or 20 p.p.m. The resistance of zirconium sponge to water corrosion is decreased wit increase of nitrogen content. A useful compilation o physical and mechanical properties and notes on th melting and casting, forming and fabrication, joining machining and heat treatment enhances the value o the chapter.

The corrosion resistance of the metal is improved he purer the metal. A zirconium specimen may ometimes fail after a long time in water at 600° F. 316° C.), even though its composition cannot be lifferentiated from that of material which continues o have a low corrosion-rate for a much longer time. mpurities such as cobalt, molybdenum, tungsten, ead, zinc, thorium, vanadium, beryllium and oxygen ppear to have little effect on the corrosion resistance, but tantalum and niobium and tin appear to have a beneficial effect. Notes are included on the corrosion of zirconium by solution and by gases such as air, hydrogen, oxygen and nitrogen and by liquid metals and fused salts. The chapter ends with notes on various zirconium systems, including zirconium, aluminium, carbon, chromium, iron, hydrogen, nickel, nitrogen, oxygen, thorium, tin, titanium and uranium, and is in general a useful contribution to the literature on reactor technology.

The chapter on graphite is informative but makes no mention of the behaviour of graphite in a neutron lux other than a passing reference to its susceptibility to irradiation damage at low temperatures. Useful comments are made on protective techniques for graphite.

The handbook was originally a classified volume for use in the Commission only, and the volume available to the general public suffers from limitations and reservations. In many instances a large number of the references quoted are classified. On the assumption that the list will eventually be declassified, it is wise to include such references ; but this will not reduce the sense of frustration of a reader anxious to read further in the subject and denied access to the classified literature. As more information becomes declassified, this effect should be minimized.

There are a useful appendix of selected physical constants of the elements, and a table of thermal neutron absorption cross-section of the elements arranged in order of increasing magnitude. Tables of temperature conversions, engineering conversion factors, a metallurgist's periodic system, a glossary of metallurgical terms, a nomograph for interconversion of weight and atomic per cent, and a vapour pressure chart of metals are included.

Throughout the handbook a number of important observations occur representing the results of lengthy investigations. These will be recognized by the reader with personal experience of investigations in the field of atomic energy. A. B. McIntosh

TIME AND LIFE

Evolution of the Vertebrates

A History of the Backboned Animals through Time. By Prof. Edwin H. Colbert. Pp. xiii+479. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 72*s*. net.

A Guide to Earth History

By Richard Carrington. Pp. xv+240+16 plates. (London: Chatto and Windus, Ltd., 1956.) 21*s*. net.

THERE are many reasons why vertebrate palæontology should be attractive, the principal being that the materials are macroscopic and the elucidation of them leads to the clarification of the sources and development of man himself. Furthermore, in Britain, France and the United States there is a long and interesting personal history attached to the growth of the subject. It may be significant that from these three countries there have recently come important contributions to the teaching literature on the vertebrate groups. These two books are of differing purpose, each of which reflects important aspects of approach.

Dr. E. H. Colbert's "Evolution of the Vertebrates" naturally takes precedence both in time and purpose, for the work is said to be designed for the general student and the lay reader, and the writing is certainly precise and lucid enough for both; but it will appeal most strongly to the advanced or graduate student who is already familiar with the zoological and physiological facts of vertebrate life.

Dr. Colbert sees the subject in the round, with all his experience as collector, museum conservator and university professor. He also knows the difficulty in deciphering much of the evidence and the ease with which the sensational rather than the conservative inference can be made. He therefore writes informatively but restrainedly.

The book covers the whole of the vertebrate field, individual groups being dealt with factually, but the overall, ecological, picture is not forgotten. It is made clear that the story of vertebrate evolution in time is not a series of changing geological scenes working up to a climax but rather a bubbling up of life that pervades the barriers of geological formations and overflows the boundaries of continents. Wisely, there are chapters on the relationships of faunas and tables of stratigraphical comparisons.

It is here that the European student will be more at a disadvantage than his American counterpart, for the richness of American discovery overshadows that of other countries and limits of space inevitably demand the omission of many interesting European forms. One feels that some of the references to European stratigraphical divisions are a little vague. Apart from this, there are very few lapses, though the student should observe that the word Oligocene does not mean "many recent" forms.

The production of the book and the illustrations by Mrs. Lois Darling are excellent. The latter are nearly all restorations, and some readers would have welcomed a few more factual or diagnostic illustrations of parts of animals. The phylogenetic diagrams are especially useful and attractive. The book as a whole will be a valuable addition to the class library and should be of great help to many British students as an additional source of information.

Mr. Richard Carrington's book, "A Guide to Earth History", covers an even wider field and is frankly addressed to the general reader rather than the student. Its author is a gifted writer and an amateur zoologist who has many qualifications for the task he essays, but he must depend on others for many of the facts in a book that covers the evolution of the Earth as well as that of the forms of animal and plant life that precede, and some of which lead to, the emergence of man. Sometimes this more vicariously acquired information betrays itself or dates itself as, for example, when the author writes that "fossils, for the last fifty or sixty years have been universally recognized for what they are". The repetition of the recapitulation theory is also probably an error of this kind.

But such things apart, the rest of the book makes a good introduction to the world of fossils and the evidence they provide of the history and progress of life. The generally accepted facts are well, and sometimes finely, portrayed, and a large series of illustrations by Maurice Wilson help to round off the story. There is an especially good bibliography. Furthermore, the work is written from the European point of view. Many non-geologists will find this a highly satisfactory statement, and quite a number of geologists can use it as a stepping-stone to further, more academic, studies. W. E. SWINTON

ASPECTS OF MARINE SCIENCE

Papers in Marine Biology and Oceanography

Dedicated to Henry B. Bigelow. By his former Students and Associates. (*Deep-Sea Research*, Supplement to Volume 3.) Pp. xx+498. (London and New York: Pergamon Press, Ltd., 1955.) 75*s*. net; 10.50 dollars.

IN 1927 the United States National Academy of Sciences set up a committee, with Henry B. Bigelow as secretary, to report on the part which the United States should take in a world-wide programme of oceanographic research. One of the major results of the inquiry was the foundation of a new research institute at Woods Hole, Massachusetts, in 1930 with Bigelow as its first director, a post which he held for ten years, before asking to be relieved in order to devote more time to his own researches. To commemorate the twenty-fifth anniversary of the Woods Hole Oceanographic Institution, which now enjoys an outstanding reputation throughout the world, this volume has been prepared and dedicated to Dr. Bigelow by his former colleagues and students.

The forty-eight contributions to the volume comprise both original research papers and review articles. It would be impossible to review them individually or even refer to the names of all the authors or the titles of their papers. The impression which one gets from the volume as a whole is how well it bears out Bigelow's own view in 1931, expressed in his book, "Oceanography: its Scope, Problems and Economic Importance", of the essential unity of the science of the sea and the close interrelationships between all its aspects—biological, geological, chemical and physical. Many of the papers themselves deal with such relations, and others, while confining themselves to work in one field, can be seen, at the same time, to fall into a general pattern.

The zoological papers range from systematic studies, such as that by P. L. Kramp on medusæ, to those on the behaviour of animals in the sea. A review of the recent researches on hearing in fishes and cetaceans is given by D. R. Griffin. A. S. Romer, in "Fish Origins—Fresh or Salt Water ?", examines the fossil evidence from European and American sources. Several papers are concerned with the relations between one kind of marine organism and another. C. E. Lucas's paper on external metabolites and E. Steemann Nielsen's on plankton algæ and bacteria are examples. Studies relating to the productivity of the sea and to problems of fisheries research are also represented.

A large group of papers is concerned with surveys of physical conditions, particularly water movements, and their relation to the circulation of nutrients and to the distribution of plant and animal life. Regional accounts are given of the Gulf of Venezuela by A. C. Redfield and of Long Island Sound by G. A. Riley. Discussing coastal currents and fisheries, C. O'D. Iselin refers to a new programme for the investigation of coastal currents which has been started at Woods Hole. G. Wüst contributes a study of current velocities in the deep and bottom waters of the Atlantic.

A number of papers deal with the geology of the ocean floor or the relation of sediments to the chemical or biological features of the water above them. A paper by the late H. C. Stetson discusses the differences between the Atlantic and Gulf terraces of the United States. An account of new instruments, by which they have taken water samples within 5–50 cm. of the bottom, is given by J. Brouardel and L. Fage. There are papers by F. B. Phleger and by Frances L. Parker on foraminifera, and by H. Pettersson on manganese nodules and oceanic radium.

This volume gives a stimulating impression of the position of marine science to-day and of some of the lines along which one may expect future advances to be made. K. F. BOWDEN

EARLY SCIENCE IN MEXICO

Montaña y los Origenes del Movimiento Social y Cientifico de Mexico

Por Prof. José Joaquin Izquierdo. Pp. xvi+442. (Mexico, D.F.: Ediciones Ciencia, 1955.) n.p.

THE colonization of the New World by Spain in the sixteenth century was carried out on an ambitious scale. In Mexico, then known as Nueva España, the Royal and Pontifical University was founded in 1553, and various types of medical institutions were also set up. At that time these establishments were as good as those of the Old World, but during the next two centuries, the many advances in science and medicine that were made in Europe did not reach or were not accepted in Mexico, and towards the end of the eighteenth century the courses in medicine taught in Mexico City had not changed in any way since they were instituted in the sixteenth century.

In this most interesting volume, Prof. J. J. Izquierdo has taken as his principal subject the life of the Mexican-born doctor, botanist and social reformer, Luis José Montaña (1755–1820); but interwoven with details of his life is a carefully documented account of the contemporary knowledge and teaching of science and medicine in Mexico, so that it is in effect a study in the history of science rather than a biography.

Montaña was a child of unknown parentage, reared in an orphanage, whose intelligence and aptitude for study took him to the University of Mexico, where he first graduated B.A. in 1771 and then took up the study of medicine. At that time the five chairs in medicine at the University included one in astrology, and Hippocrates and Galen were still the revered masters. There was no connexion with the hospitals and no clinical teaching. It was not until at the end of the eighteenth century that the advances made in Europe began to be recognized and accepted in Mexico; and in their gradual introduction Montaña played an important part.

Montaña was interested in botany and the pharmacological uses of the native plants. The dispatch in 1787 of a scientific expedition from Spain so collect and study Mexican plants, and the opening in 1789 of a Royal Botanic Garden in Mexico City itself, furnished Prof. Izquierdo with material for a particularly interesting botanical chapter, which includes some account of the herbal knowledge of the Aztecs.

Montaña's belief that medicine should be scientific, and studied in conjunction with the natural sciences, brought him into association with the progressive party. The story is an involved one, linked with a particularly stormy period in Mexican politics, and the reforms he sought to establish were not achieved until some thirteen years after his death.

This well-printed book, illustrated with many reproductions from contemporary literature, has an appreciative preface by Prof. H. E. Sigerist. It is a welcome addition to accounts of scientific progress in the Americas. An English translation would be valuable and enable it to reach a larger circle of readers.

J. M. EYLES

MAGNETIC AMPLIFIERS

Magnetic Amplifiers

By H. F. Storm. (Contributors: E. F. W. Alexanderson, H. H. Britten, W. D. Cockrell, F. J. Ellert, E. A. Harty, H. W. Lord, W. Morrill, H. M. Ogle and P. A. Vance.) (General Electric Series.) Pp. xix+545. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 108s. net.

THE early development of the magnetic amplifier was slow, probably because of the competitive influence of the electronic valve. During recent years this early neglect has been remedied, and there is now a great mass of technical articles describing developments of this robust and useful piece of apparatus. There have, however, been very few books published on this subject, and most of them have not been major works.

The issue of a 550-page book by Dr. H. F. Storm and his colleagues of the General Electric Co., Ltd., is both welcome and opportune. The advantages of having parts of a subject covered by different specialists in one book is normally obtained at the expense of some lack of continuity in the treatment, and this book is no exception; but Dr. Storm has written Chapters 4–20, covering the whole theory of the amplifiers, so that a large part of the book forms a satisfactory unit.

The first three chapters include the theory of magnetism, a description of magnetic materials and methods of testing them. Then follow Dr. Storm's chapters, and finally there are chapters on core and coil assemblies, metallic rectifiers and various applications of amplifiers.

Dr. Storm's treatment of the magnetic amplifier emphasizes the difference between operation with free even harmonics and suppressed even harmonic currents. Not all readers will agree that this is the best approach to the subject; but his treatment is clear and thorough, and he deals with both the steady-state operation and transient operation with resistive and inductive loads in considerable detail. He then covers the operation of feedback, including the amplistat and the bridge amplistat. Some aspects of the subject are not adequately covered, as, for example, the use of push–pull amplifiers and high-speed amplifiers, but this is a minor blemish in an otherwise excellent work.

Dr. Storm's mathematical arguments are often made needlessly difficult to follow by references to earlier equations which are spread over several chapters. A little judicious repetition of these equations would simplify the reader's task without adding unduly to the volume of the book. The figures are clear and well chosen, and there is a remarkable freedom from misprints in both text and figures in the chapters written by Dr. Storm; but the standard is rather less high in the other chapters.

This is a book which all serious students of the magnetic amplifier will need to have, but it is of postgraduate standard and is not easy reading. The highly glossed paper on which the text is printed is tiring to the eyes.

TEXT-BOOK ON HEAT ENGINES

Technology of Heat

By Prof. H. Wright Baker. Pp. xiii+427. (London and New York: Longmans, Green and Co., Ltd., 1956.) 36s. net.

WITH few exceptions, the contents of this book fall within the compass of what has until recently been called heat engines. There are various approaches to the theory of heat engines, and the author, Prof. H. Wright Baker, is to be congratulated on the line which he has followed in this work.

Although much is already familiar from Prof. Baker's edition of "William Inchley's Theory of Heat Engines", a broader background is given to the material. This has been arranged to introduce the diagrammatic representation of states, processes and working cycles at the earliest possible opportunity. Armed with this knowledge, the student (used in the generally accepted sense) is in a position to tackle the succeeding chapters on air compressors, steam engines and turbines, internal combustion engines, the gas turbine, and refrigerators and heat pumps, because all these chapters include a copious supply of cycle diagrams. As a direct consequence of the diagrammatic approach, steam and gas turbines appear as separated items.

Fuels and combustion are not confined to the chapter with that heading, additional information being given throughout the book. Both the title "Technology of Heat" and the preface heading "An Introduction to the Industrial Uses of Heat" give the impression that these aspects receive more detailed attention than they in fact do. For example, little is said of liquid fuels, and notable omissions are mentions of heat of formation, liquid fuel burners, and kinetics of combustion. Perhaps a little space could be found for mention of these at the expense of some of the matter referring to the reciprocating steam engine.

The chapter on heat transfer is welcome for the amount of information it contains on the radiation, conduction and convection processes. The final chapters deal with more practical aspects, namely, waste heat recovery and heat balances, and notes on testing. Example questions are appended to most chapters.

Although not including any innovations, this book is to be recommended to students working for degrees, Higher National Certificates, etc. As a general introduction to a very broad field of study, it requires additional references to more specialized books and articles.

T. D. PATTEN

Rectangular-Polar Conversion Tables

Designed and compiled by E. H. Neville. (Royal Society Mathematical Tables, Vol. 2.) Pp. xxxii + 109. (Cambridge: At the University Press, 1956. Published for the Royal Society.) 30*s*. net.

THE problem of determining the polar coordinates (r,θ) of a point with Cartesian coordinates (x,y), according to the equations $x = r\cos\theta$, $y = r\sin\theta$, is a common one presenting no theoretical difficulty. In particular, the solution of algebraic equations by root-squaring necessitates the conversion in complex form (that is, $z = x + iy = re^{i\theta}$), and (to quote the author's words) without a quick passage between corresponding pairs of values, the process is a flight of fancy rather than a technical revolution.

Almost all the tables hitherto available for the above conversion have been single-entry in character, employing the argument $t = y/x$ and then working in terms of arc tan t and $\sqrt{(1 + t^2)}$. The use of two independent variables, for which purpose this volume is primarily designed, clearly facilitates the calculations and obviates the danger of serious numerical errors.

The table covers the triangular range $1 \leqslant y \leqslant x \leqslant 105$, the upper limit 105 being chosen as convenient for typographical purposes. The arrangement of the entries is extremely ingenious, each page containing exactly 106 pairs of entries to 15 decimal places. To explain the detail of the arrangement, it is sufficient to take a page at random, say p. 35, and to describe its contents. These are $x = 35$, $y = 1(1)35$, with values of r and θ in degrees, followed by $y = 35$, $x = 35(1)105$, with values of $\log_e r$ and θ in radians. As will thus be seen, the logarithm table not only provides symmetry but also avoids repetition.

A substantial introduction precedes the main table just described and is mainly concerned with methods of interpolation required in using the table. Many illustrative examples are provided, and no effort has been spared to clarify the details of the numerical computation involved.

A bibliography of relevant and collateral tables is also provided, and the volume concludes with six supplementary tables, which include page-indexes for r and $\log_e r$ and the first 1,688 integer-denominators of the Farey series of order 105, the use of which is required in the interpolation methods.

J. H. PEARCE

Second Thoughts on Radio Theory

By "Cathode Ray" of *Wireless World*. Pp. 409. (London: Iliffe and Sons, Ltd., 1955. Published for *Wireless World*.) 25*s*. net.

THIS collation of articles contributed by "Cathode Ray" to the *Wireless World* during the past twenty-five years forms a kind of running commentary on the development of radio theory during the period. The impenetrable pseudonym might stand for a synthetic figure, made up of experts of the panel; but the characteristic manner of writing suggests that one person, and a very forceful person, too, is the author of them all. In any event, one feels that during this period few individuals can have done more to encourage and browbeat radio engineers to face fundamental difficulties and think out the solutions for themselves.

The book contains some forty articles on basic ideas, circuit elements and techniques, and calculations. Each article starts in a simple fashion; but the topic is dissected and discussed so thoroughly in detail that towards the end the reader is being piloted skilfully through the deeps. The light conversational style which is "Cathode Ray's" own way of driving his points home may not appeal to everybody; but there is wisdom and sound judgment behind it. Intolerance of jargon and slipshod thinking and an irreverence towards the pundits who frame definitions in a spirit of confusion, flash out fiercely from time to time. It is good to see so many o these articles together in permanent form, and the publishers are to be congratulated on an excellent volume.

G. R. NOAKES

The Biology of a Marine Copepod

Calanus finmarchicus (Gunnerus). By Dr. S. M Marshall and Dr. A. P. Orr. Pp. vii + 188 + 18 plates (Edinburgh and London: Oliver and Boyd, Ltd. 1955.) 21*s*. net.

NEARLY two hundred years ago *Calanus* was discovered in northern Norwegian waters and classified by its discoverer, Bishop Gunnerus o Trondheim, as *Monoculus finmarchicus* among the "Insecta Aptera". As an important link in the marine food chain, especially as a staple food of th herring, this copepod has become the object of study of workers in a great variety of branches of biology

The authors, having themselves worked on *Calanus* for many years, have written a well-produced and eminently readable survey of knowledge concerning the systematics and distribution, the anatomy, reproduction, development and life-cycle of the animal Chapters dealing with biometrical data, the animal's chemical composition, its food and feeding mechanism lead to a summary of work on its respiration, vertica migration, and its relation to inorganic and organic environment.

An extensive list of references and a most carefully prepared index add to the value of a book which should prove to be an asset to zoologists, marine biologists and naturalists alike.

Clays and Clay Minerals

Proceedings of the Second National Conference on Clays and Clay Minerals, University of Missouri October 15–17, 1953. Edited by Ada Swineford and Norman Plummer. (Sponsored by the Committee on Clay Minerals of the National Academy of Sciences—National Research Council; University of Missouri State Geological Survey of Kansas.) Pp. viii + 504 (Washington, D.C.: Publication 327, National Academy of Sciences—National Research Council 1954.) 4 dollars.

DURING recent years the study of clays and clay minerals has received much attention, and th widespread interest in the subject has been fostere by the establishment of national and internationa groups and committees. In the United States, National Conference on Clays and Clay Minerals, th second of its kind, was held at the University c Missouri in the autumn of 1953, and this volume i a record of the proceedings. It contains thirty-seve separate contributions from authors with a wid variety of experience, dealing with the geology genesis, chemistry, mineralogy, crystal structure and physical and mechanical properties of clay deposit and clay minerals, and includes a number of X-ray studies. The volume is well printed and illustrated and adequately indexed, and forms a valuable contribution to the literature of clays.

ENERGY REQUIREMENTS OF EUROPE

THE report on Europe's future needs of energy recently issued* by the Organization for European Economic Co-operation contains a most interesting examination of the position and includes a number of important recommendations which have been derived from a detailed study by a group of experts. This study has comprised the collection and examination of data and opinions emerging from international organizations and professional circles able to provide the pertinent information.

The report reveals that the consumption of all forms of energy in Europe, which in 1955 was equivalent to 730 million tons of coal, is rising so rapidly that in 1975 it is likely to reach a figure equivalent to 1,200 million tons of coal. This forecast is based on a maintenance of the competitive position of the member countries of the Organization for European Economic Co-operation in an expanding world economy, and the consequent raising of their standards of living.

According to the report, the share of the total requirements expected to be covered in 1975 by the production of primary energy in Western Europe will amount to an equivalent of 750 million tons of coal, as against 580 million tons in 1955. It emphasizes that it would be erroneous to believe that nuclear energy will make large contributions to the supply of energy available in Western Europe in the next twenty years. Rather is the limit of this contribution put at 80 million equivalent tons by 1975, or only 8 per cent of the total requirements. Unless a special effort is made to promote the indigenous production of primary energy, the remaining gap between energy requirements and indigenous supplies would have to be bridged by imports of coal and oil, the cost of which would amount in the target year 1975 to about £1,800 million at present prices. This may well present a formidable problem for some member countries in its effect on the balance of payments. The dependence of Western Europe on imported energy, with its inherent risks as regards matters of both economics and security, and the certainty of rising prices, must imply the serious need for a determined effort on the part of all member countries to develop further their indigenous production of all forms of energy. All reserves of energy will be needed in the future, and it is important to note that coal will be the mainstay of the energy economy in Europe for many years to come. Further, an increased output of coal must depend on long-term investment, on the development of improved mining methods, and on adequate terms of miners' pay and employment. In effect, coal must be given the outlook of a modernized and stable industry, which will attract able young men to join it. No doubt in time the competitive position of the coal industry may be affected, for after 1975 nuclear energy is expected to free the coal burnt in thermal power stations to an increasing extent. Nevertheless, this coal will be needed for other purposes for which nuclear energy cannot replace it. Meanwhile, the ultimate importance of nuclear energy and the difficult and novel problems involved in its development should induce member countries, both jointly and individually, to make a large and technological effort in the nuclear field. Additional effort will be necessary in the harnessing of undeveloped sources of hydro-power and for new sources of oil and natural gas.

The share of oil in supplying the energy needs of Western Europe must also rise rapidly. The concomitant factors governing this rise are the increasing consumption of oil for transport of all kinds, the advantages of oil for certain purposes and its increasing use as a substitute for coal owing both to its lower cost and to the shortage of coal. The world's reserves of oil will be adequate for this requirement, but large investments must be made by the oil companies in Western Europe as well as abroad.

Special importance is attached to the up-grading of primary into secondary forms of energy, such as gas and electricity. These latter are essential to a rise in productivity of many industries and are associated with improvements in the standards of living. These secondary forms of energy are the means of utilizing with the greatest efficiency the limited supplies of primary energy, and contribute to their greater adaptability. The fact that they can be produced with the aid of different forms of primary energy introduces an element of flexibility into the energy economy, which serves to lessen the rigidity inherent in the coal industry.

A potent factor in reducing the menacing gap between indigenous production and the overall requirements of energy resides in the still existing possibilities of saving energy by economies at every stage, from its winning and conversion in the energy industries to its final utilization in industry and in the home. The European Productivity Agency of the Organization for European Economic Co-operation is called upon to render assistance in this field, and member countries are urged to institute organized efforts for the purpose of energy saving.

The report urges Governments to give competition full play, in order that the consumer may be able to have maximum choice between the different forms of energy. This requires Governments to establish energy policies suited to their own circumstances, needs and resources in order to deal effectively with the urgent problems in the demand for and the supply of energy. The establishment of such policies should include some co-ordination between the different forms of energy, and be followed by the recommended co-ordination of the separate Governments' energy policies. This would result in increased co-operation at international level. At the same time, it is recommended that Governments should endeavour to avoid legislative or administrative restrictions likely to retard the development of sources of energy, or to jeopardize their efficient utilization. Further, in the framing of overall social, economic and financial policies, due consideration should be given to the effects of taxation, price maxima and wages structures on the efficient production and use of energy.

Other means of co-operation are recommended in this report. There are important chapters on the financial aspects of the energy problem; thus in energy prices, the impact of such prices on the balance of payments, and the investment needs of the energy industries in the period under review, are considered. In this context, there is recommended the mutual supply of capital needed for the production of energy as well as the pooling of research and development programmes. Again, it is considered to be of mutual benefit for member countries to increase their co-operation in the fields of exchange of energy, of man-power for the production of energy and of information and experience.

---

* Europe's Growing Needs of Energy: How can they be Met? A Report prepared by a Group of Experts. Pp 120. (Paris: Organization for European Economic Co-operation; London: H.M. Stationery Office, 1956.) 400 francs; 8s.; 1.25 dollars.

In the final chapter of the main report, it is pointed out that only a cursory examination of the many important general problems envisaged was practicable. More detailed examination was therefore necessary, and it proposes the setting up of a new committee of individuals selected for their experience in this field, to act as advisers to the Organization. Not only should this new committee examine the conclusions of the present report and follow their implementation, but also it should review periodically both energy statistics covering the pertinent factors, and, with the help of the economic and other technical committees, the forecasts of energy requirements and supplies. The terms of reference should also include the search for problems which need further investigation.

Extensive appendixes are attached to the report. They indicate the sources of the information obtained, which covered an authoritative field concerned with trade union and managerial responsibility. The forecasts on which the main conclusions have been based were derived by four independent methods. Assumptions were made as to the anticipated level of employment, the standard of productivity, the level of working hours and, most important of all, that no abnormal events would intervene, such as a war.

Most valuable to the general interested reader are the reviews of the energy situations in the individual countries concerned, some twelve in number. They give the individual statistics for the various sources of energy as to production, the reserves and future prospects, the most important of the pertinent factors as to imports and exports of energy, and the developments in the nuclear field.

Of the primary sources of energy in the period 1956–75 in Western Europe, the annual production of coal may increase, according to present plans, from 480 million tons, as at 1955, to 520 million tons; but some further capacity must be provided to replace exhausted pits, to the extent of 190 million tons per annum. These additions will call for investments in the neighbourhood of £3,000 million, exclusive of coke ovens, pithead power stations and briquetting plant. Lignite, mostly in Germany, will require £570 million. Water developments to result in an increase of about 150 per cent capacity in 1975, as compared with 1955, may cost some £7,600 million. Indigenous sources of oil and natural gas are less tangible factors to assess, but are expected to require a sum equivalent to that of coal, namely, £3,000 million.

For the provision of secondary energy, coke and coal gas will require a sum slightly in advance of this last figure, and for thermal electricity the overall investments may amount to the considerable figure of £17,700 million. This is exclusive of the provision for transmission and distribution of electrical energy. The total investment to cover all requirements in the period 1955–75 could reach the astronomical figure of £50,000 million, or an annual average of £2,500 million. The investment provided in 1955 was £1,580 million. Thus an increase by some 60 per cent of outlay is included in the present plans for development.

The report is illustrated by a number of graphs, relating to the position and the prospects in the United Kingdom, France, Switzerland and Sweden, which emphasize clearly the importance of coal to Great Britain.

R. J. SARJANT

THE MEASUREMENT OF BODY RADIOACTIVITY

CONFERENCE AT LEEDS

THE problem of measuring the radioactivity of the human body is exciting interest in many countries. A conference, the first of its kind devoted to this problem, was held during April 16 and 17, in the Department of Medical Physics of the University of Leeds. Delegates attended from Denmark, Sweden, Germany, the United States, Canada, Australia and Great Britain, and they included representatives from almost all the groups known to be engaged in this field.

In a short introduction, Prof. F. W. Spiers outlined the aims of the conference. Of first importance was the bringing together of as many as possible of those actively working on the problem of body radioactivity and others interested directly in it. It was intended to consider particularly the external methods of measuring body γ-ray emission and their possible limits of sensitivity. High-pressure ion-chamber techniques are already adequate, he said, to measure amounts of γ-emitters in the body of the order of 2 ng. radium equivalent (1 ng. = 10^{-9} gm.), that is, well below the recommended maximum permissible levels[1]. An improvement in γ-sensitivity of ten times appears to be feasible with scintillation techniques, but perhaps the special importance of the latter is in their possible application to measuring very low levels of β-emitters in the body. The conference would also include consideration of techniques other than external detection giving data on body radioactivity.

Papers were read by representatives of each of the three groups who have used high-pressure ion-chamber methods. Dr. B. Hultqvist (Institute of Radiophysics, Stockholm) discussed results obtained at Stockholm using two arrays each of twelve high-pressure chambers in a laboratory which, being at 55 metres depth below solid rock, is well shielded from cosmic rays. To exclude local radiation, walls, floor and ceiling are lined with tanks containing Thames water (since this has a considerably lower radioactivity than Stockholm water) and the radon content of the air is reduced by forced ventilation. With these precautions to reduce the background, the maximum uncertainty of a single measurement on a human being, taking 3–4 hr., is ± 1 ng. radium equivalent. Published results[2] include investigations of 306 normal individuals divided into three age groups, and it appears that differences are due to potassium content rather than radium, and that for uncontaminated persons the radium content is well below 1 ng. Differences in the radium content of drinking water supplies are insufficient to account for all the differences in radium content. Dr. Hultqvist also described a survey of the radon and thoron content of air in Swedish homes of various building materials[3], and showed that the accumulated radioactivity is greater in the lungs than in any other part of the body, a factor to be borne in mind in whole-body measurements.

Mr. J. Rundo (Atomic Energy Research Establishment, Harwell, formerly at the Finsen Laboratory, Copenhagen) next described the apparatus at Copenhagen[4] which was designed at Harwell following the pattern of that at Leeds. It uses four measuring cylinders together with four 'backing-off' chambers and a vibrating-reed electrometer feeding into an automatic recorder with an averaging device. Its chief application has been in the study of thorium burdens, a complex problem involving such unknown quantities as the fraction of each daughter product that might be present and, in many cases, the duration of the burden. By calibrating the apparatus with bottled samples of thorium dioxide at different known fractions of radioactive equilibrium and also by means of a model in which the thorium is realistically distributed, it is possible to make reasonable interpretations of the body measurements. Some use of the apparatus has also been made in bremsstrahlung measurements on phosphorus-32 administered to patients.

Experience with the Leeds apparatus was described by Dr. P. R. J. Burch (Department of Medical Physics, University of Leeds). Dr. Burch spoke of the basic considerations concerning the sensitivity and calibration of a body γ-ray monitor. In the case of high-pressure integrating ion-chambers, the cosmic-ray component of the background contributes most of the statistical error. A chamber design was described which should enable errors to be reduced by a factor of from two to three by ensuring that most penetrating cosmic-ray particles would produce roughly equal amounts of ionization both in the register and the backing-off chambers. The principle is being incorporated in an apparatus for recording the γ-ray intensities from the atmosphere and ground, together with the cosmic-ray intensity. Application of the idea to a body γ-ray monitor should enable the normal body γ-ray emission to be measured with a probable error of ± 5–10 per cent in an observation period of 2 hr. By using different wall materials, different gases and different gas pressures in chambers above and below the body, a considerable measure of discrimination of radiation quality would be possible. However, for clinical studies an apparatus is needed capable of giving a standard error of about 2 per cent in a short (¼-hr.) measurement, and the apparatus under construction designed to achieve this was described. Five tank units containing a liquid scintillator and each viewed by two photomultipliers will be mounted around a chair on which the patient reclines. The components of this apparatus, the steel-shielded room in which it is to be used and also the original high-pressure ion-chamber apparatus[5] were available for inspection.

In the discussion following the three papers on high-pressure chamber techniques, mention was made of the importance of avoiding errors due to contamination from clothing and from radon or thoron in patients' breath, and even due to the potassium-40 content of reading material used by the patient during measurement.

The first afternoon session (with Dr. K. Z. Morgan, of the Oak Ridge National Laboratory, United States, in the chair) was devoted to scintillation techniques. Dr. E. C. Anderson (University of California, Los Alamos Scientific Laboratory) described work with the Los Alamos scintillator[6]. He pointed out that the principal advantage of the large liquid scintillator lies in its high sensitivity, permitting the use of short observation times. This greatly increases the scope and capacity of the apparatus. Moreover, with liquid scintillators, almost the entire solid angle around the patient may be filled, as compared with the 10^{-2} or 10^{-3} convenient with sodium iodide crystals. Since sensitivity is dependent on the ratio $(\text{sample})^2/\text{background}$, the advantage of high counting-rates is obvious. The present Los Alamos apparatus has a cylindrical space 18 in. in diameter in which the patient lies. The surrounding 500 litres of liquid scintillator is viewed by an array of 108 photomultiplier tubes, each 2 in. in diameter. The whole is screened by 5 in. of lead, with 2 in. of lead at the patient's head. An exposure of 2 min. is adequate to estimate the normal potassium content of the body with a standard error of ± 10–20 per cent. Statistical stability of the background is better than 1 per cent, which corresponds to 5 per cent in the normal body measurements. Measurements of body activity against age and sex give essential agreement with those described earlier by Dr. Hultqvist. An improved correlation has been found if the potassium-40 activity of each patient is plotted not against gross, but against lean, body-weight. The latter is found by a tritium determination of body-water, which is assumed to be 70 per cent of lean body-weight.

It was a disappointment that Mr. Marinelli's group (Argonne National Laboratory), which has made such notable contributions to the subject, could not be represented. Dr. Anderson was able to include in his paper a description of the work being carried out at Argonne with a single large sodium iodide crystal in conjunction with a room lined with 8-in. steel. The extreme sensitivity of the apparatus was indicated by its detection of what may be traces of cæsium-137 from radioactive fallout, the emission of 0·66 MeV. radiation from tested humans corresponding to a level of 0·005 µc. of cæsium-137 if this interpretation is confirmed.

A joint paper on scintillation techniques by Dr. Denis Taylor and Mr. R. B. Owen (Atomic Energy Research Establishment, Harwell) was read by Mr. Owen after a brief reference by Dr. Taylor to preliminary scintillation work done in connexion with the Copenhagen project. It described an apparatus utilizing four sodium iodide crystals (1¾ in. in diameter, 2 in. thick) giving a standard error for normal body radioactivity of 10 per cent for a 10-min. observation. In its application to phosphorus-32, the standard deviation was equivalent to 30×10^{-9} c. of the isotope. It is proposed to use larger crystals (4½ in. in diameter × 2 in.) with a reduced potassium impurity, when the standard deviation on a 10-min. exposure should be only 3 per cent. A further reduction may be possible if still purer crystals combined with top-channel analysis are employed. Mr. Owen considered the sensitivity to be expected with the proposed apparatus in the detection of americium-241 and plutonium-239 in the body. He believes that it may be possible to measure 6 × 10^{-8} c. of americium-241 from the 59-kV. emission and amounts of the order of the maximum permissible level of plutonium-239, utilizing its 17-keV. X-rays.

In the discussion which followed, it was suggested that the location of plutonium in bone may reduce Mr. Owen's estimate, while Dr. Roesch (G.E.C., Richland, Washington) quoted measurements of transmission of plutonium-239 radiation through patients which suggested a factor of 30–40 for absorption from centre to surface of the chest. Although on present evidence it seems that the measurement of a fixed skeletal burden of plutonium would be difficult, the detection of a recently inhaled burden while still in the lungs appears feasible. In closing the scientific session of the first day, Dr. Morgan stressed the need for applying, if possible, the methods of measuring body radioactivity to the determination of the distribution fractions and effective rates of elimination for various organs for cases of single ingestion as well as for continuous exposure.

The second day's scientific programme was devoted to indirect methods of measurement of body burdens. The morning session, under the chairmanship of Dr. Katharine Williams (Atomic Energy Research Establishment, Harwell), was opened by Dr. Wright H. Langham (University of California, Los Alamos Scientific Laboratory) with an account of the application of urine excretion studies to the determination of plutonium in the body. The urinary excretion curve for plutonium is best fitted with a power function; fæcal excretion is similar but with different parameters. Measurements of urine samples taken on different occasions may be matched to the theoretical power-law curve and the effective limits of exposure deduced. Where the ratio of fæcal to urinary excretion is very high, it is suggested that unabsorbed particles from the lung have found their way up the trachea and have thence been swallowed. Dr. Langham suggested a division of hazard according to the solubility of the plutonium particle and proposed a model of lung mechanism on the basis of which, in the case of insoluble particles, the lung burden is ten times the systemic burden, agreeing fairly well with calculations based on the fæcal/urinary ratio. However, the difficulties inherent in excretion analysis emphasized the desirability of whole-body measurement for plutonium if feasible.

In answer to a question, Dr. Langham said that there is remarkable uniformity in the excretion patterns of different individuals, possibly a consequence of plutonium being chemically unlike any element naturally found in the body.

Dr. J. B. Hursh (University of Rochester) then spoke of the radium content of cremation ashes, natural waters and some common foods. His results[7] for whole-body cremation ashes based on radon assay are about 1/100 of Krebs's earlier value[8] of 10^{-8} gm. average radium content, and Dr. Hursh reviewed other American work giving results in agreement with the lower value. He next described measurements on the radium content of natural and filtered waters in various parts of the United States and showed that they do not bear out the theory that drinking water is the main source of radium burden. The radium content of several common foods has been analysed and suggests that they are a possible source of at least a part of the norma burden.

It was apposite that the next paper was read by Dr. H. Muth (Max-Planck Institute for Biophysics Frankfurt-am-Main) on measurements of norma radium burdens, for he and his colleagues have likewise measured the activity of cremation ashes of German subjects, and their results are in agreement with those of Hursh and Gates[7]. They measured the radon content by a dual ion-chamber system and also by α-pulse counting. In addition, measurements were made of the activity of various tissue samples which were consistent with the total-body results Dr. Muth described determinations of radioactivity of drinking water supplies, wells and thermal springs and also gave preliminary figures for the radium content of some foodstuffs. The general agreement with Dr. Hursh's results was very satisfactory.

In the discussion, Dr. K. Z. Morgan stressed the importance of a knowledge of the radium content in the gonads, Dr. Muth having included some relevant data in his paper.

The final afternoon session, under the chairmanship of Dr. M. Faber (Finsen Laboratory, Copenhagen), was opened by Mrs. M. M. Hindmarsh (Nuffield Institute for Medical Research, Oxford) presenting studies by herself and Dr. Janet Vaughan on α-track measurements of radium in bone. She described photomicrographic and autoradiographic studies of sections of bone from a man, much of whose working life had been concerned with the handling of radium. In general, radium in the shafts was associated mainly with the Haversian systems, whereas in the ends it was concentrated in regions of high calcification. The calculation of body burden from α-track counting was described[9]. Emphasis was laid on the non-uniformity of distribution and it was pointed out that the dose in a small cavity (5μ) might be twenty times the average assessed on the basis of uniform distribution.

Prof. F. W. Spiers described a joint investigation with Dr. Burch in which γ-ray measurements on the same case were compared with α-track results reported in the previous paper. It had been possible to measure the γ-ray emission from the cadaver eight hours after death and afterwards to measure a number of representative bones in sealed containers after radioactive equilibrium between radon and radium had been attained. The total radium burden (0·48 μgm.) estimated from the bone measurements indicated that at the time of death the radon excretion in breath was 65 per cent. A body radium burden of 0·39 μgm. deduced from the α-track studies is in reasonable agreement with the γ-ray assay in view of the limited number of sections counted. It has been shown that the total life-dose to osteocytes in a 5-μ canal is of the order of 1,20 rad and not very dependent on the assumptions on period of intake. An estimate was also given of the distribution of dose to the bone marrow.

In a paper on the importance of radon and its decay products for the normal radiation dose in humans, Dr. A. Schraub (Max-Planck Institute fo Biophysics, Frankfurt-am-Main) considered the influence of geological and meteorological factors on the distribution of radon and its products in the soil the atmosphere and water supplies. Figures wer given for air concentrations in various sites and conditions, and the dose to the lungs of city dwellers estimated on the basis of measurements of air content of closed rooms.

The final paper, by Dr. W. P. Grove (Radiochemical Centre, Amersham), described experience with the measurement of radon in breath, a method which is specific to radium. The procedure for obtaining a representative sample of breath was described and details given of a technique for collecting the charged active deposit electrically on a metal foil coated with a phosphor for scintillation counting. Several cases had been sent to Leeds for total γ-measurement, and comparison with the exhaled radon suggested an excretion of about 60 per cent.

Reviewing the whole meeting with special reference to external methods of measuring body radioactivity, it could be concluded generally that scintillation techniques have reduced the limits of detection of 'hard' γ-emitters from figures of the order of 2×10^{-9} c. in a 2-hr. observation with ion chambers to about 10^{-10} c. obtainable in 15 min.; and that β-emitters such as phosphorus-32 can be detected at levels of the order of 3×10^{-8} c. Detection of levels of this latter order appears to be possible for a weak γ-emitter such as americium-241.

It was generally agreed that the success of the conference was in large measure due to its informality and to the many opportunities for discussion it afforded. Delegates were entertained by the Board of Governors of the United Leeds Hospital during the scientific sessions held in the Leeds General Infirmary, and also by the University of Leeds at a dinner at which the vice-chancellor, Sir Charles Morris, presided.

It is hoped in due course to publish in full the proceedings of the conference in a single volume.

ECOLOGY AND NATURE CONSERVATION

A MOST successful meeting was held in Edinburgh during June 20–28 by the International Union for the Conservation of Nature and Natural Resources, hitherto known by the misleadingly restricted title of International Union for the Protection of Nature. There was an excellent attendance both of animal and plant ecologists, and of administrators, engineers, town-and-country planners, foresters and other interested professions. More than thirty countries were represented. Among the visiting scientists were: Prof. Roger Heim (president of the Union), director of the Paris National Museum of Natural History, and Profs. J. G. Baer (Neuchatel), E. Beltran (Mexico), H. Gams (Innsbruck), T. Monod (Dakar), and Dr. Ira Gabrielson (United States) (all members of the executive board), and also Profs. J. Berlioz and F. Bourlière (Paris), Prof. G. P. Dementiev and Dr. L. K. Shaposhnikov (U.S.S.R. Academy of Sciences), Dr. W. Engelhardt (Munich), Dr. E. H. Graham (United States Soil Conservation Service), Dr. A. Marcello (Italy), Prof. G. J. Van Oordt, Mr. M. F. Morzer-Bruyns, and Dr. V. Westhoff (Netherlands), Mr. Fairfield Osborn (president of the U.S. Zoological Society and the Conservation Foundation), Mr. Roger Tory Peterson (United States), Mr. Hugh M. Raup (director of Harvard Forest, U.S.A.), Mr. F. N. Ratcliffe (Australia), Prof. L. G. Romell (Sweden), Prof. R. Sparck (Copenhagen), Prof. W. Szafer (Poland), Prof. V. E. van Straelen (Belgium) and Dr. E. B. Worthington (Africa).

A number of directors and other officers of national parks, nature reserves, forests, and interested societies also attended, including: Mr. J. H. Baker (executive director of the U.S. National Audubon Society), Mr. H. H. Bennett (recently chief of the U.S. Soil Conservation Service), Mr. M. C. Bloemers (director of the Netherlands Government Nature Protection Department), Mr. H. J. Coolidge (director of the Pacific Science Board), Mr. R. de Vilmorin (president of the French Société d'Acclimatation), M. F. Edmond-Blanc (secretary general of the Conseil Internationale de la Chasse), M. J-E. Harroy (Governor of Ruanda Urundi), Mr. R. Knobel (director of national parks, South Africa) and M. F. Vidron (secretary general of the Conseil Supérieure de la Chasse, France).

The United Kingdom was represented, among others, by Profs. W. H. Pearsall, P. W. Richards, M. L. Anderson and R. Matthew, and by Mr. A. B. Duncan, Sir Basil Neven Spence, Mr. E. M. Nicholson, Dr. F. Fraser Darling and a number of members of the staff of the Nature Conservancy, and representatives of the National Coal Board, the National Parks Commission, the North of Scotland Hydro-Electric Board, the Forestry Commission, and a number of other public authorities and government departments, together with Lord Hurcomb (president), and other representatives of the Society for the Promotion of Nature Reserves, Mr. Peter Scott (director) and members of the research staff of the Wildfowl Trust, Capt. Keith Caldwell and Lieut.-Col. C. L. Boyle (Fauna Preservation Society), and others.

The meeting was notable in bringing together for the first time picked representatives of so many different professions, whose activities affect land use and management, and who are increasingly feeling the need for a concerted approach to their problems. For this purpose the agenda of the technical meeting consisted of four topics, three of which related to land use:

(1) Management of nature reserves on the basis of modern scientific knowledge. This subject elicited several important papers. Ecologically, one of the most interesting was Mr. Raup's reconstruction, based on nearly fifty years of organized studies by Harvard University, of the relation of present to past woodlands in eastern North America. Briefly, he held that the conception of a stable climax forest is an illusion (even where there is no human interference), and that natural catastrophes, particularly wind-throw during storms, and also fire, occur within the life-span of most trees on most areas—while climatic and other environmental changes keep the

vegetation from settling down on any one consistent pattern. He compared the process with the similarly drastic effects of frost action on the arctic tundra, and he demonstrated techniques of tracing, through woodland soil profiles, storm havoc going back so far as four hundred years.

Dr. Ira Gabrielson gave an excellent summary of United States techniques in nature reserve management, and Mr. E. M. Nicholson submitted a detailed review of the principles of management of natural areas, based on a comparison between European and North American practice.

Brief mention must also be made of Prof. Romell's valuable analysis of the extensive man-made elements in Scandinavian habitats, and the Wildfowl Trust's review of aspects of the management of wildfowl refuges in Britain.

Mr. Fairfield Osborn presided over these sessions, with Dr. F. Fraser Darling as *rapporteur*. Unfortunately, the number of participants in this section was too large to permit adequate discussion.

(2) The second theme was devoted to an international comparison of the course and repercussions of myxomatosis in rabbits, and a critical review of factors affecting its future development. Mr. F. N. Ratcliffe, who presided, described the ecological consequences of myxomatosis in Australia, and Prof. Bourlière, the *rapporteur*, ably summed up the remarkably consistent experience of different countries, as shown by the papers describing the effects on the French, British and Netherland flora, and on predatory and competing animals, particularly in Britain.

Mr. H. V. Thompson (Ministry of Agriculture, Fisheries and Food) expressed the personal view that in England the rabbit population may, provided there are sustained efforts at control, be held down to roughly a fifth of its level before myxomatosis. The relationship between the more virulent and less virulent strains of the virus, and the considerations affecting possible repeated use of the virus among rabbit populations which have already been attacked by it, were fully reviewed.

(3) The third theme was a return to land-use problems, with special reference to the rehabilitation of areas biologically devastated by human disturbances. Dr. R. Lessing (London) initiated a lively discussion on colliery refuse and mining subsidence. He stated that the present method of surface disposal of colliery refuse means waste, nuisance and damage, and that the National Coal Board will soon be sterilizing nearly 1,000 acres a year, worth between £50,000 and £100,000, by covering it with some 40 million tons of mined refuse containing an estimated fuel value equivalent to that of nearly 10,000,000 tons of coal; much of this could be utilized by the design and installation of suitable plant, which has now been shown to be technically practicable. At the same time, compensation for subsidence resulting from the bringing of this material to the surface is estimated at £3,000,000 a year; this could be prevented or minimized by storage underground of solid material. Naturally these conclusions proved controversial and were in particular criticized by a representative of the National Coal Board. The meeting concluded that, after reviewing a wide range of specialized evidence on the practice, the time has come for all governments concerned to initiate official technical investigations in order: (*a*) to determine whether this type of spoil should not in future be disposed of underground in order to avoid the serious waste of land, fuel and other natural resources which it involves; (*b*), to fix time limits within which either the practice of dumping should cease or the matter should be further reviewed; (*c*) to examine the possibility of dealing by legislation or otherwise with existing spoil heaps of this type.

In contrast, the North of Scotland Hydro-Electric Board was warmly congratulated by delegates for its successful efforts to reconcile hydro-electric development with preservation of amenities, and of the fauna and flora. The Board's work was inspected on the ground during a visit to the Pitlochry and Tummel areas.

The joint consideration by ecologists, engineers and land planners of a number of problems arising from large civil engineering works produced some of the most interesting discussions, and it was generally agreed that much greater efforts should be made in future to ensure that the knowledge and advice of ecologists were sought at an early stage by governments, and by agencies undertaking works capable of altering the landscape.

The chairman for this theme was Prof. W. H. Pearsall, and the *rapporteur* was Dr. W. Engelhardt.

(4) The fourth, and closely related, theme dealt broadly with the relationship of ecology with landscape planning, with Mr. R. J. Bentham, chief of the Landscape Department of the Netherlands State Forest Service, as *rapporteur*.

Dr. E. H. Graham contributed an important paper on Nature protection as part of land development, based on extensive American experience. Some interesting papers were contributed from Germany on ecological landscape management in torrent catchment areas, and on the protection of Nature in relation to structure of landscape.

Mr. A. Glikson, an architect from Israel, contributed a thoughtful review of the relationship between landscape planning and ecology, and discussions also took place on other aspects, such as the making and use of vegetation surveys, and the part played by shelter belts in land use, on which the discussion was opened by Prof. M. L. Anderson (Edinburgh).

So far as it is possible to summarize in a few words the results of so much diverse discussion, it may be said that a start has at last been made towards creating the long-needed link between ecology and the various technologies, arts and industries concerned in or affecting its application to landscape. Aesthetic, scientific and economic considerations all have to be reconciled in any satisfactory treatment, and hitherto they have been largely isolated from one another. We are still a long way from being able to formulate any theory to reconcile these conflicting approaches; but we can at least now see that the methods in general use to-day fall far short of the best modern practice and are in too many cases producing serious or even disastrous long-term consequences. The first remedial steps must be to educate the authorities and individuals concerned not to cling to a few favoured methods (such as burning of heather, surface dumping of mining refuse, or shooting of predators), but to turn their attention to the desired results (for example, improved grazing, getting rid of unwanted materials, or maintaining game populations) and to rely on trained scientists to find the best methods for getting these results. There is a close parallel here to the role of research in the Defence Services, where again it has been necessary to show that victory only comes from readiness to replace preconceived and cherished methods by newer and more appropriate ones. World-wide comparisons are particularly fruitful in the conservation field, and they show clearly that even government agencies and large undertakings are still clinging to methods equivalent to the bow-and-arrow stage in warfare. Both the International Union and national conservation agencies will need to be strengthened to find the right answers and to see that they are put into practice. The high technical quality of the Edinburgh meeting and the impressive representation of the various professions concerned gives encouragement to believe that they will not fail.

The meeting was accompanied by an international film week, at which a wide range of films was shown from countries as far apart as India, Japan, the U.S.S.R., South Africa and Canada, illustrating the increasing potentialities of colour films for scientific as well as education and propaganda purposes. The effects of fire, erosion, pollution and destruction of plant and animal life were vividly illustrated. One general comment was that in too many cases the skill and thoroughness exhibited in obtaining the pictures was not yet matched when it came to cutting and editing the material As a result of these comments, progress in this direction can be confidently expected.

About 180 photographs of mammals, reptiles, birds, insects and plants were exhibited from the British National Collection of Nature Photographs, newly formed by the Nature Conservancy, and the Royal Scottish Museum arranged an interesting exhibition on "Man and the Balance of Nature" which included a good deal of material from the recent International Exhibition organized by the International Union for the Conservation of Nature and Natural Resources in Paris.

The papers and discussions of the technical meeting will be published as soon as possible, but in the meantime the Nature Conservancy would be glad to reply to any inquiries, addressed to it at 19 Belgrave Square, London, S.W.1.

INTERNATIONAL UNION OF CRYSTALLOGRAPHY

MEETINGS IN MADRID

THE meetings of the International Union of Crystallography held in Madrid during April 2–7 were a departure from the previous practice of the Union in several ways. For the first time, the main interest of the symposium was not focused on structure on a molecular scale, but on structure on a scale intermediate between molecular and optical-microscopic. Also for the first time, two of the Commissions of the Union organized an extended series of open meetings. The programme was very crowded, and even with the help of colleagues I am able to give only an incomplete account.

Teaching of Crystallography

The Congress of the Union held in Paris in 1954 saw the beginning of the present general interest in the teaching of crystallography and the establishment of a Commission[1] on such teaching. In preparation for the Madrid meetings, this Commission had circulated a questionnaire, and from the replies and the statements given by several national representatives it was obvious that crystallography, though it grew suddenly out of the morphological stage as long ago as 1912 and has made swift progress since, has not received full academic recognition even yet. Full courses in crystallography at the undergraduate level are extremely rare, and most of the undergraduate teaching given elsewhere is slight and incidental to studies in the older sciences. The best opportunity for serious study of, and training in, crystallography is postgraduate, and the prior training in other subjects is a great advantage. For crystallography embraces a field far wider than is often realized—even by those engaged in other sciences—and far wider than its name suggests. In just over forty years we have gained an insight into the variety of structures, perfect and imperfect, and into the structural reasons for the chemical and physical properties of solids, that far outstrips our knowledge of liquids and gases. This new insight is being rapidly exploited by industry, but scarcely any use has been made of it in modern presentations of the established sciences.

It was generally agreed that, instead of trying to squeeze formal courses on crystallography into the already overcrowded degree courses, it would be both easier and more natural to introduce it incidentally and gradually, thus making the student structure-conscious even from his school days. The preciseness of crystal models and the directness of this approach could transform completely much of the teaching of the basic chemical laws, and at the university degree level could simplify the presentation of material in many subjects. In some subjects, such as physics, the emphasis would be less on the diversity of structures and more on the relations between structure and physical properties (especially anisotropic properties), and on diffraction phenomena in two and three dimensions. Mineralogy has had, of course, the closest academic relation with crystallography, but it is remarkable how many departments still concern themselves mainly with morphological and petrological techniques, paying scant attention to structure and its connexions with geochemistry—and (so it would appear from the discussions in Madrid) even less to the techniques of structure analysis. On this point, contributions at the meeting from the U.S.S.R. were especially interesting. The bias of Russia has been traditionally mineralogical, but for the few who undertake the very extensive courses the training is comprehensive and modern. In Europe generally there is great variety in the approach, and the extent of training is dependent on local educational tradition and personal initiative. In North America there are a very few, and very good, schools of crystallographical research and postgraduate teaching, but very little is done at the undergraduate level. Japan is worthy of mention for the scale and quality of its post-war work in crystallography, but it is not clear how far the subject has penetrated into undergraduate teaching.

The ideas exchanged at Madrid on the order of presentation and on teaching aids were valuable, and showed that, despite the variety of contexts in which the subject is introduced, geometrical concepts are the most important and usually the earliest topics treated, with crystal chemistry a close second. Crystal physics, except perhaps for crystal optics, is usually a poor third.

There is no shortage of good text-books for the specialist student, but there is an urgent need for the provision of new or revised text-books for college, school and, indeed, general use. These should rely much more on the structural approach to chemistry, physics, metallurgy, mineralogy and biology.

Apparatus

The papers on crystallographical apparatus were mainly concerned with advances in techniques in powder diffractometry and with the development of X-ray tubes and associated equipment. The properties of the various quantum-counting devices used in diffractometry have now been investigated in detail over the X-ray range of wave-lengths, and it appears that the thallium-activated sodium-iodide scintillation counter, used with a pulse-height analyser, has considerable advantages over the Geiger or the proportional counter[2]. The analyser, when set to accept the proper range of pulse amplitudes, is very effective in reducing background from diffuse scattering of the continuous spectrum, from specimen fluorescence, and from radiation other than X-rays. The high quantum efficiency of the scintillation counter, and its uniform response over the range of X-ray wave-lengths normally used, gives it a uniformly high figure of merit (based on equal weights for observed counting rate and peak-to-background ratio), and makes it very suitable for fluorescence analysis as well as for powder and single-crystal diffraction work.

The application of focusing monochromators to the improvement of powder diffractometry has also received a good deal of attention. In one of the more promising arrangements the specimen is used in transmission with a reflecting monochromator placed in the divergent diffracted beam; a standard diffractometer can readily be adapted for this. Though the peak intensity (for values of 2θ between 15° and 85°) is lowered by a factor of about two, the non-characteristic background is eliminated, and the lines are considerably sharper than with the standard arrangement set for maximum resolution. Since preferred-orientation effects are reversed in transmission, this arrangement, in conjunction with the standard one, provides a sensitive means for detecting preferred orientation in a given specimen. In another arrangement the monochromator is placed between the source of X-rays and the specimen, which is examined in transmission. This method has advantages for low-angle work.

The development of fine-focus X-ray tubes has given rise to new problems in the design of both tubes and auxiliary apparatus. A focal spot of ideal shape and brilliance is difficult to obtain, and when a line focus is required, various aberrations arise very readily. The design of line-focus tubes was discussed, and characteristic examples of aberrations and their correction were illustrated. It was emphasized that, to use these tubes to the best advantage, the tube and the diffraction camera need to be designed as a single instrument. A Weissenberg camera with film radius 1 cm., and an axial retigraph with specimen-to-film distance 1 cm., were noteworthy examples. Improvements in the design of rotating-anode tubes were also described.

Single-crystal counter diffractometry continues to develop, and some account was given of an arrangement in which the mechanical precision required is less than in earlier equipment, so that its construction is practicable in small workshops.

Analysis of biological specimens can be carried out on the electron microscope by taking photographs with three different beam velocities; these photographs are used to produce a composite coloured image of the specimen. The different colours are characteristic of the atomic numbers of the elements present and indicate their distribution in the specimen.

A simple analogue computer[3], based on two d.c. bridges, was described. In its general form the machine will give the product of three sine or cosine terms, so that it can be used for calculations of structure factor, Patterson function or electron density, although the computer that has actually been constructed was specially designed for the calculation of structure factors.

Structure

Individual papers in the symposium on structures on a scale between the atomic and microscopic dimensions were of great interest. Perhaps because it was a first attempt to organize a symposium in this dimensional range, it was a little difficult to discern a 'structure' in their order of presentation, and one was left with a somewhat scrappy impression of the field. The most impressive were the papers on proteins and sub-proteins, investigated both by electron microscopy and by X-ray diffraction. There was an interesting group of papers on the structure of collagen, including a demonstration of the equivalence of the results obtained by the two methods. Another group of papers was devoted to viruses[4]. Consideration of the structure of molecular viruses led to some interesting applications of point-groups, including a cubic point group, 532, possessing a five-fold axis[5].

The papers on metals showed extreme diversity, from surface films through tin whiskers to more conventional structure work on phases with very large unit cells. Work on field-emission microscopy[6] was noteworthy. The investigation of structure and structural imperfections in metals at 5° K. was interesting both for its results and for the ingenuity of the apparatus, which provided for cold-working the specimens in the spectrometer at the low temperature.

The work on proteins and metals formed two reasonably consistent groups, although the arrangement of the programme somewhat obscured this. There were, in addition, a large number of papers difficult to classify, on topics ranging from commercial greases to orientation of cellulose in filamentous algae. One was led to wonder if a number of smaller meetings, more restricted in scope, with a single subject only claiming attention at any one time, would not be more valuable than a large conference with several simultaneous sessions.

OBITUARIES

Prof. C. van Riet Lowe

THE death of Prof. C. VAN RIET LOWE in Johannesburg, South Africa, on June 17 is a severe loss to rchæology not only in South Africa but also to the cience as a whole.

Prof. van Riet Lowe trained as a civil engineer at he University of Cape Town, but interrupted his tudies to serve with distinction in the First World War, first with the South African Artillery and later with the Royal Horse Artillery, in East Africa, Egypt, Palestine, Italy and France. In 1940 he gain donned uniform to take command of the Witwatersrand University Training Corps Battery.

In 1920 he entered the Civil Service as an engineer n the Public Works Department and reached the op of his profession in 1931, when at the age of hirty-seven he became chief engineer of the Department.

During 1923–28 he was in charge of bridge construction in the Orange Free State. He was quick to eize the opportunities this presented for archæological field-work in his spare time. He discovered a arge number of Stone Age sites, began the long eries of research publications which at the time of is death exceeded 130, and rose rapidly to the forefront of South African archæologists. In 1929 he ollaborated with Prof. A. J. H. Goodwin in publishing "The Stone Age Cultures of South Africa", which still is the most comprehensive account of outh African prehistory.

In 1935 the Government established the Bureau f Archæology, which later became the Archæological urvey of the Union of South Africa, and van Riet Lowe was the obvious choice as its first director. The University of the Witwatersrand provided ccommodation for the new institution and appointed he director to a chair of archæology. At this time, oo, the Commission for the Preservation of Natural nd Historical Monuments, Relics and Antiques was econstituted under a new Act of Parliament, and Prof. van Riet Lowe became a member and secretary f that body. He was thus entrusted with building p these new institutions from their beginnings and cquitted himself of all three tasks with great istinction.

Prof. van Riet Lowe's contributions to archæology annot be reviewed in a brief note. One of his first rojects as director of the Archæological Survey was geological and archæological study of the gravels f the Vaal River, undertaken jointly with the Geological Survey of the Union, which for the first ime gave us a climatic sequence and cultural corelation in the south of the continent. A similar tudy of the Little Caledon River has just been published. He directed the important excavations t Mapungubwe undertaken by the University of Pretoria, and the excavation of the Cave of Hearths n the Makapan's Valley, which proved to contain a omplete Stone Age sequence from the end of the Earlier Stone Age to modern times.

He was assiduous in recording and studying the great wealth of prehistoric art which adorns the South African rock shelters, on which he became the eading authority, and welcomed the collaboration of he Abbé Breuil, who was invited by the late General Smuts to join the staff of the Archæological Survey during the Second World War.

Van Riet Lowe travelled widely in the pursuit of his researches. In 1931, when he represented the South African Association for the Advancement of Science at the centenary meeting of the British Association, he made a study of the important archæological collections in England and France and visited many sites in company with such authorities as Burkitt, Henry Balfour, Breuil, Harper Kelley and Henri Martin. In 1937 he undertook a long journey of archæological exploration through Egypt and the Sudan, East Africa, the Belgian Congo and the Rhodesias, and two years later was invited by the Government of Uganda to describe the prehistory of that important territory in collaboration with Mr. E. J. Wayland. This work was published as Part 2 of a memoir of the Geological Survey of Uganda; Part 1 on the Quaternary geology of the area, by Mr. Wayland, is in preparation. He twice paid official visits to Mozambique to advise the Government of that territory on the organization of archæological research and the preservation of monuments.

His long service in many spheres brought him many honours. He was a past president of the South African Association for the Advancement of Science, the South African Archæological Society and the South African Museums Association. He was awarded the South Africa Medal by the South African Association for the Advancement of Science in recognition of his distinguished research, and the medal of the Historical Monuments Commission for his work in that field. He received the degree of D.Sc. from the University of Cape Town and was a Fellow of the Society of Antiquaries and the Royal Society of South Africa. He represented the Government of South Africa on the International Historical Monuments Commission of the League of Nations and later became a member of the International Commission on Monuments of Unesco. He took an active part in the Pan-African Congresses on Prehistory in Nairobi, Algiers and Livingstone and was invited by the Governments of Iraq and Spain to visit their countries.

Dr. C. E. Eddy

CECIL ERNEST EDDY, whose death at the age of fifty-six following a heart attack has been reported from Perth, Western Australia, was one of Australia's best known and best loved scientists. Born in Albury, in New South Wales he crossed the State border and was educated in Victoria at Colac High School and the University of Melbourne, from which ultimately he received the degree of D.Sc. However, it was to the whole of Australia that Eddy's services were rendered as director of the Commonwealth X-ray and Radium Laboratory since 1935.

Following graduation, he took the M.Sc. degree at Melbourne in 1924 and became research physicist in the Department of Natural Philosophy in 1927. In 1927, also, he was awarded a Rockefeller Fellowship, and studied in England during 1927–28. Cambridge, as was to be expected, left its mark on him, as on many great figures in the world of physics. It is worthy of note that by 1929 Eddy was reporting the use of the Geiger counter for the detection of β-rays transmitted by aluminium. In the next few years, in collaboration with his chief, Prof. T. Laby, he published in the *Proceedings of the Royal Society* papers on the analysis of materials by means of X-ray emission spectra.

In the 1930's and 1940's Eddy was a not infrequent contributor of articles to the *British Journal of Radiology*. From these can be deduced not only his native interest in the fundamentals but also his administrative acts in introducing methods of modern dosimetry into the Australian practice of radiology.

Indeed, as a scientific administrator, Eddy was outstanding. His battles to bring all that was best in the world to his own country will probably only be known and appreciated there. But in recent years he was to become more widely known in international scientific relations. With the introduction after the Second World War of radioactive isotopes, it fell to Eddy to negotiate abroad for materials and equipment with which Australian physical, biological an medical research could keep in step with the mos advanced countries of the world. In the field o personal and public protection against radiations an radioactivity he was an active participant in th deliberations of the International Commission o Radiological Protection, and lately he had repre sented his country on the committee of the Unite Nations Organization called on to evaluate th world problem of radioactivity. Of this notable bod he was elected chairman; his loss at this stage, afte such a successful start of this Committee's delibera tions, will be deeply felt.

In addition to his membership of Australia scientific societies, Eddy was a Fellow both of th Physical Society and the Institute of Physics i Britain.

J. F. LOUTIT

NEWS and VIEWS

Geology in Edinburgh: Prof. Arthur Holmes, F.R.S.

PROF. ARTHUR HOLMES, who shortly retires from the regius chair of geology in the University of Edinburgh, has been distinguished for his contributions in two main fields of his science. In his early days at the Imperial College of Science and Technology, London, his association with Lord Rayleigh led him to pioneer the investigation of the geological implications of radioactivity. Major contributions to the problem of the age of the Earth and to the assessment of the Earth's thermal history have come from his pen; for example, he first directed attention to the importance of potassium as an emitter of radiothermal energy. It is not too much to say that his work revolutionized previous conceptions of geological time and of the history of the Earth. At the same time, he continued the interest in igneous petrology first manifested in his account of his explorations in Mozambique with a series of outstanding studies which have included such diverse subjects as the alkaline igneous rocks of North-west Angola, the Arctic basalts, the Whin Sill and the North of England dykes, the petrography and chemistry of the potash-rich lavas of Uganda, and the origin of kimberlite. He has never been content with mere petrographical description; through all his work there has run the search for a fundamental mechanism capable of producing the diversity of rock types which the Earth's crust exhibits, leading him far in the direction of syntexis and metasomatism under the influence of emanations.

In 1924, Holmes went to Durham as first head of the newly founded Geology Department; there he remained until his translation to Edinburgh in 1943. His great gifts as a teacher and his lucid text-books on petrography and physical geology have made his influence on the science profound and lasting. His later years have been full of honours; he was elected to the Royal Society in 1942; a foreign member of the Royal Swedish Academy of Sciences and of the Royal Netherlands Academy of Science in 1947 and of the Paris Academy of Sciences in 1955. This year he received the Wollaston Medal, senior award of the Geological Society of London, and is to be the recipient of the Penrose Medal of the Geological Society of America.

Prof. F. H. Stewar

DR. F. H. STEWART, senior lecturer in geology i the Durham Colleges, is to succeed Prof. Holmes i Edinburgh. An Aberdonian, Dr. Stewart wa educated at Fettes College, Edinburgh, and in th University of Aberdeen, where in 1937 he gained first-class honours B.Sc. in geology. Having bee awarded the Kilgour Research Studentship, he com menced investigations of igneous petrology unde Prof. T. C. Phemister; these he continued at th Department of Mineralogy and Petrology at Cam bridge under Prof. C. E. Tilley during 1939–41. H was then appointed to the physico-chemical researc establishment of Imperial Chemical Industries a Billingham. Here he became interested in the potash bearing salt deposits, and began his studies on th cores of Eskdale No. 2 borehole, the first boring t find potassium evaporites in Britain. In 1943 h was appointed lecturer in petrology in the Universit of Durham, and here the work begun in Scotlan and at Billingham has been brought to fruition.

Dr. Stewart is chiefly known in the field of igneou petrology for his study of the layered basic comple of Belhelvie, probably the best example in Britain o a type which includes also the great Bushveld bod in South Africa. After completing this work, h began a revision of part of the Tertiary volcano o Skye, which is still in progress. His contributions t the petrological study of the saline deposits hav been many and varied, but they have serve especially to reveal the numerous and comple mineral substitutions which have taken place in th evolution of potassium-rich zones. The publicatio of his work on the borings undertaken for Messr. Fisons around Robin Hood's Bay, Yorkshire, awaited with much interest. In the meantime, D Stewart's petrological investigations have foun recognition in the award of a moiety of the Lye Fund, by the Geological Society of London in 195. and of the Mineralogical Society of America Awar for 1952. In following Arthur Holmes from Durha to the Edinburgh chair, Frederick Stewart take with him a broadly-based reputation in mineralog and petrology; but these subjects do not represe the sum of his interests. His enthusiasm for fiel geology in all its aspects, his skill as a collector o fossil fishes and his knowledge of ornithology reve him as a naturalist in the best sense.

esearch Medicine, University of Pennsylvania: Prof. Colin M. MacLeod

DR. COLIN M. MACLEOD, professor of microbiology nd chairman of the Department of Microbiology at ew York University College of Medicine since 1941, as been appointed John Herr Musser professor of search medicine and chairman of the Department f Research Medicine of the School of Medicine of the niversity of Pennsylvania. He succeeds Dr. William . Stadie, who has been made emeritus professor. . Canadian by birth, Dr. MacLeod is a graduate of cGill University Medical School, and during 1934–1 he was a member of the staff of the Rockefeller nstitute for Medical Research in New York. Dr. acLeod's special fields of interest are infectious iseases, microbial genetics and immunology. He is member of the Armed Forces Epidemiological oard and was president of that Board during 947–55. He is a member of the Executive Committee f the Division of Medical Sciences of the National esearch Council, and last year was a member of ie Special Committee on Medical Research of the ational Science Foundation. Since 1945 he has been ssociate editor of the *Journal of Immunology*. Dr. acLeod is a member of the U.S. National Academy f Sciences, the American Association of Immuno- gists (president 1951–52), the Harvey Society resident 1955–56), and the Society of American acteriologists, among others.

urricane Research in the United States

THE Woods Hole Oceanographic Institution, assachusetts, supported by the United States eather Bureau, the United States Navy and the ffice of Naval Research, is to trace the hurricanes, hich bring disaster to the eastern seaboard of the nited States, to their birthplace over the ocean. hey are formed in summer between about latitudes ° and 8° N., and so far as is known at present they ccur after a period of abnormally light winds across ie northern half of the trade-wind belt. The Woods ole scientists suggest that these conditions lead to nusually high sea-surface temperatures and abnorm- lly high humidity in the lower layer of the atmo- here—probably because fewer sea-salt nuclei are rried up from the surface and less rain is initiated. hen there is sufficient instability to produce winds raise whitecaps, more nuclei will be carried up, nd under extreme conditions the condensation, elease of latent heat and increased convection will row into a hurricane.

To make the basic observations and to test such eas, a 125-ft. ex-coastguard cutter has been con- erted for research in marine meteorology. In dition to the usual meteorological and upper-air bservations, detailed measurements will be made of ie temperature and state of the sea surface. The ork will be done in close collaboration with an air- orne team supplied by the U.S. Weather Bureau. better understanding of the physical processes hich produce the hurricanes will facilitate pre- iction, and there is a hint in the plans that it may e practicable to prevent the formation of a large ganized disturbance by using rain-making tech- iques at scattered points before the conditions ecome critical. The new research ship *Crawford* rries eight scientific workers and a crew of fourteen. he carries supplies for a month, and fuel for 6,000 iles at 12 knots. She sailed from Woods Hole for ie hurricane-generating region on July 3.

Atoms in Industry

P.E.P. (Political and Economic Planning) has recently issued two pamphlets entitled "Atoms in Industry", which provide an excellent appreciation of the British nuclear power plan and of the problems associated with its implementation. The first pamphlet gives estimates drawn from recent publications of the probable cost of the electricity to be generated in the early gas-cooled, graphite-moderated stations; deals with the increased importance relative to coal-fired stations of capital costs and the likely impact of the operation of sources of nuclear power on the national economy; and outlines the organization of the United Kingdom Atomic Energy Authority and its present and possible future relationship to manufacturing industry. The second discusses the factors governing the location of nuclear-power stations and the safety and insurance of these stations; and summarizes the steps which are being taken to establish effective international co-operation. It also incorporates a section dealing with radioactive isotopes, the techniques and economics of their application in industry, and the arrangements which the Atomic Energy Authority has made for their exploitation. It is stated in the conclusion that the account has been written strictly in the context of the present state of commercial developments, so that no attempt has been made to outline and compare the more advanced forms of power reactor which may emerge as alternatives to the gas-cooled, graphite-moderated type within the next decade, or to consider the prospects of nuclear propulsion.

The pamphlets will be found useful both by those directly concerned and those to whom developments in the peaceful utilization of nuclear energy are only of general interest. They would have been even more valuable to both classes of reader, however, had attention been given to the extent to which these developments may be hampered by the present shortage in Britain of scientists, technologists and technicians, as was made very clear in an article in *Nature* of December 24, 1955.

Technical Education and Industry

THE Federation of British Industries has issued a memorandum welcoming the White Paper on Technical Education but is reserving overall appraisal until the universities have published their plans for technological education for the quinquennium 1957–62, pointing out that account must also be taken of the 'bulge' in population which now has its peak among those entering the secondary schools. In the view of the Federation, the plans are not specific enough. No attempt has been made to specify the time within which the proposed increases in the numbers of technicians and technologists is to be achieved, nor is it indicated how the Government proposes to secure the essential co-operation from the public, parents, teachers and industry. While suggesting curtailment of the development of new colleges of advanced technology in the London area, the Federation appears to accept the Government's target figure and merely queries the distribution. It emphasizes the value of co-operation between industry and technical colleges at the level of the governing bodies, but stresses also the value of advisory committees of industrial specialists and teachers. The White Paper is regarded as too complacent in regard to the recruitment and training of teachers ; but while calling for concrete Government plans in this field, the Federation's memorandum gives little indication of concrete support from industry in the release of staff for part-time teaching. The Federation regards the day-release system as a valuable method of providing further training for potential technicians and technologists, and urges its member firms to increase the volume of day-release for this purpose. It agrees that many women could be trained in technological subjects, and holds that industry provides ready openings for women who are technically qualified on appointment. The adoption of 'sandwich' courses by more firms is urged, and such courses are discussed in some detail, particularly in regard to the importance of background information, co-operation between technical colleges and firms, amenities, finance, and the relevance of the proposals of the National Council for Technological Awards.

International Council of Museums : Conference in Switzerland

THE fourth general conference of the International Council of Museums was held in Switzerland during July 2–9 under the presidency of Dr. George A. Salles, director of the French museums. Some 250 delegates from more than thirty countries attended, including at least four from Great Britain. The conference was held in Basle, Zurich and Geneva, and French and English were used as the working languages. Working groups dealing with specified subjects replaced the usual lectures and discussions. Dealing mainly with display and museum technique, this arrangement was eminently satisfactory and stimulating to those who took part. This was especially the case where broad principles of museology were discussed rather than when a particular exhibit or room was the subject for the working group. A series of five public lectures was delivered under the central theme of "The Museum in our Time". These were given by Dr. George Salles, Sir Gavin de Beer, Dr. Bengt Thordeman, Dr. Karl Bassler and Mr. Francis Taylor. The programme of lectures and working groups was liberally interspersed with visits to museums and to art galleries and receptions with very generous hospitality. The International Campaign for Museums, to be held in the week commencing October 8 next, was formally proclaimed by M. André Leveille, director of the Palais de la Découverte, Paris, and it was decided to hold the next conference in 1959 in the Scandinavian countries with headquarters in Stockholm.

Products of Starch Hydrolysis

Messrs. Vittorio, Krotkov, Nelson and Bidwell have examined the products of starch hydrolysis and their metabolism, using tobacco leaves in which the starch content is very high after photosynthesis (*Canad. J. Bot.*, 34, No. 2, 209 ; 1956). Carbon-14 labelled tobacco leaf starch, digested with *N* sulphuric acid in a boiling water bath, was not completely hydrolysed to glucose even after 24 hr. After three hours hydrolysis, paper partition chromatography with butanol–ethanol–water solvent revealed that besides glucose there were four carbon-14 labelled products with R_F values lower than glucose. When these bands were fed individually to tobacco leaves in light, they were incorporated into sucrose, glucose, fructose and starch, and were better starch formers than glucose, glucose-1-phosphate or maltose.

Tropical Tuna Resources of the Eastern Pacific

THE tropical tunas which inhabit the high seas of the shores of the Americas from California to Peru and northern Chile support the most valuable fishery of the eastern Pacific Ocean. This consists o populations of two species, the yellow-fin tuna *Thunnus* (*Neothunnus*) *macropterus*, and the skipjack (barrelete), *Katsuwonus pelamis*. In 1953, 14 million pounds of yellow-fin and 134 million pound of skipjack were produced from the eastern Pacific The preponderant share of the catch is taken by fishing vessels based on the west coast of the United States—very modern, long-range craft forming one of the most specialized fishing fleets in the world. A small but appreciable share of the catch is taken by vessels based in Peru. Most of the landings in countries other than the United States are transhipped frozen to the United States for processing as canned tuna. A scientific investigation of the tuna resources of this important fishery has been undertaken by the Inter-American Tropical Tuna Commission. A description of its work was given by it director, Milner B. Schaefer, at the United Nations conference in Rome during April 18–May 10, 1955 dealing with the Conservation of the Living Resources of the Sea.

Effects of Radiation on Dielectric Materials

A CONFERENCE on "The Effects of Radiation on Dielectric Materials" was held at the United States Naval Research Laboratory, Washington, D.C., during December 14–15, 1954, under the joint auspices o the Naval Research Laboratory and the Office o Scientific Research of the Air Research and Development Command, and the report of the proceedings has recently been published (No. PB111863 ; pp. 169 Washington, D.C. : Office of Technical Services Department of Commerce, 1956 ; 4.25 dollars). The object of the conference was to provide an exchange of information on the research programmes and progress of the various laboratories engaged in the study of the effects of radiation, and also to examine and discuss the general aspects of the wide variety of disciplines involved in this field of investigation Representatives of many United States government laboratories and of university and industrial laboratories participated in the conference, and survey talks on various aspects of radiation effects were delivered by Drs. M. Burton (Notre Dame University) R. Smoluchowski (Carnegie Institute of Technology) K. H. Sun (Westinghouse Electric Corporation) and D. Billington (Oak Ridge National Laboratory) The article by Dr. Sun, entitled "Effects of Atomic Radiation on High Polymers", is particularly valuable because of its extensive bibliography, compiled by F. A. Pecjak and the author, which consists of 217 references. The proceedings consisted of four sessions and twenty-one papers were presented. They include in addition to the survey talks, a description of research and radiation effects in insulating materials carried out at the Brookhaven National Laboratory "Radiation Effects on Glass", by N. J. Kreid (Bausch and Lomb Optical Co.) ; and several discussions of the effects of atomic radiation on polymers including polyethylene and 'Teflon', at low temperatures, and of general radiation on crystals, including diamond.

University of Leeds : Gifts

THE following gifts have been received by the University of Leeds : £2,000 from an anonymous member of the Clothworkers' Company to the Department of Biomolecular Structure, to be devoted to the furtherance of cancer research carried on under the direction of Prof. W. T. Astbury; £2,000 from the Central Electricity Authority to the Department of Agriculture, to continue during 1956–57 research on the reclamation of ash lands; £6,000 a year for two years from the Nuffield Foundation to the Department of Medicine, in support of the gerontological research unit.

Institution of Electrical Engineers: Officers

THE following will take office on the Council of the Institution of Electrical Engineers on September 30 next: *President,* Sir Gordon Radley; *Vice-Presidents,* T. E. Goldup, S. E. Goodall, Dr. Willis Jackson, G. S. C. Lucas and Sir Hamish D. MacLaren; *Honorary Treasurer,* Rt. Hon. Viscount Falmouth; *New Members of Council,* J. A. Broughall, B. Donkin, A. H. Mumford, D. P. Sayers, H. Watson-Jones and H. West.

The Night Sky in August

NEW moon occurs on Aug. 6d. 11h. 25m., U.T., and full moon on Aug. 21d. 12h. 38m. The following conjunctions with the Moon take place: Aug. 3d. 13h., Venus 3° S.; Aug. 7d. 22h., Mercury 6° N.: Aug. 8d. 03h., Jupiter 6° N.; Aug. 13d. 21h., Saturn 3° N.; Aug. 23d. 21h., Mars 12° S. In addition to these conjunctions with the Moon, Mercury is in conjunction with Regulus on Aug. 5d. 04h., Mercury 0·9° N., and is also in conjunction with Jupiter on Aug. 9d. 18h., Mercury being then only 0·2° S. of Jupiter. Mercury is too close to the Sun for observation during August. Venus rises at 1h. 35m. at the beginning of the month and at 1h. 15m. at the middle and end of the month; its stellar magnitude varies between −4·2 and −4·4 and the visible portion of its illuminated disk increases from 0·297 to 0·492, its distance from the Earth increasing from 44 to 65 million miles. Mars rises at 21h. 45m., 20h. 50m. and 19h. 50m. on August 1, 15 and 31, respectively, and during the month its brightness increases in magnitude from −1·8 to −2·5, the visible portion of its illuminated disk increasing from 0·930 to 0·991 and its distance from the Earth decreasing from 43 to 35½ million miles. Jupiter is too close to the Sun during August for favourable observation. Saturn can be observed for a short time after sunset, its times of setting being 23h. 25m., 22h. 30m. and 21h. 30m. at the beginning, middle and end of the month, respectively; its stellar magnitude remains about 0·7, while its distance from the Earth varies from 896 to 942 million miles. It has a slow eastward movement in Libra, and at the end of the month it is about 5° south-east of γ Libræ. The Perseid meteors attain a maximum about August 10–13, the radiant being at R.A. 3h. 8m., Dec. 58° N.

Announcements

THE Scottish Agricultural Industries, Ltd., post-graduate studentship at the University of Aberdeen has been awarded to R. Bain, who will work on the sorption of polyelectrolytes on mercury and on clay mineral surfaces.

THE Alvarenga Prize for 1956 of the College of Physicians of Philadelphia has been awarded to Dr. George N. Papanicoloau, director of the Papanicoloau Research Laboratory of Cornell University Medical College, for his outstanding work in the early detection of cancer.

DR. ALBERT H. MOSEMAN, formerly director of crops research in the United States Department of Agriculture Research Service, has been appointed associate director for agriculture of the Rockefeller Foundation. Dr. Moseman's activities will be associated with Foundation grants to institutions in the United States for fundamental research in agriculture, and agricultural programmes in foreign countries. He will work in association with Dr. J. George Harrar, director for agriculture.

THE University of Oxford has received from the Medical Research Council a grant of £3,655 for the continuation of research into the effects of the injection of radioactive substances being carried out in the Nuffield Department of Medicine by Dr. J. M. Vaughan, principal of Somerville College, and £2,000 for the equipment of a hutted laboratory for use by Dr. Vaughan.

THE Chemical Research Laboratory, Teddington, will hold its open days this year on October 2 (afternoon only) and October 3–4. Applications for tickets should be made to the Director before August 31. Those already on the mailing list need not re-apply.

THE second of the congresses on theoretical and applied mechanics, sponsored by the Council of Scientific and Industrial Research, India, will be held during October 15–16 in the National Physical Laboratory, New Delhi, under the presidency of Sir K. S. Krishnan. Research papers may be contributed on any of the following topics: elasticity, plasticity and rheology; fluid mechanics (aerodynamics and hydrodynamics); mechanics of solids (ballistics, vibrations, friction and lubrication); statistical mechanics, thermodynamics and heat transfer; mathematics of physics and mechanics, and methods of computation. Such papers, with three copies of abstracts, must be sent before August 15. All correspondence should be addressed to the secretary-treasurer of the congress, Dr. B. R. Seth, Indian Institute of Technology, Kharagpur.

THE Society for Water Treatment and Examination will hold its autumn meeting in the Wills Hall, University of Bristol, during September 19–21. In view of the great interest shown as a result of the publication of the third edition (1956) of "The Bacteriological Examination of Water Supplies" (Report No. 71), the Society will hold another meeting in London on November 20 (5.30–8.30 p.m.) in the Library of the Royal Society of Health, to which the Society of Applied Bacteriology, the Microbiological Section of the Society of Chemical Industry and the Institution of Water Engineers have been invited. Further information on both these meetings can be obtained from the honorary secretary of the Society, A. W. H. McCanlis, 41 Carshalton Road, Sutton, Surrey.

THE Department of Medical Chemistry of the Australian National University (with Prof. Adrien Albert in charge) will be transferred from London to the newly built John Curtin School of Medical Research in Canberra on August 10.

ERRATUM. In a communication entitled "Dependence of Snowfall on Temperature", by L. W. Gold and G. P. Williams, in *Nature* of June 16, p. 1137, it was erroneously implied that Prof. M. Bossolasco correlated frequency of occurrence of snowfall with mean daily temperature; in fact, his correlation was between frequency of occurrence of snowfall and the temperature at the time of fall.

PHYSICS IN MODERN CHINA

By Dr. E. H. S. BURHOP
University College, London

In the intensive efforts now being made to transform China from a technically backward to an advanced industrial nation, great stress is being placed on the training of scientific and technical personnel. During the course of a recent visit, I therefore took the opportunity to visit universities and scientific institutes and to discuss with Chinese scientists the methods of training employed and the problems being faced. The visit was too short to allow more than a superficial view of the present condition of Chinese science and education; but many of their proposals and practices in this field are so novel that a short account may be of interest.

The impressions reported here were gained in visits to the University of Peking, to Fu Tan University in Shanghai, and to the large technical Tsinhua University in Peking, which seems to be modelled on the Massachusetts Institute of Technology. The same general pattern exists in other Chinese universities, all of which are under the jurisdiction of the Ministry of Higher Education.

The general pattern of student life in the three centres showed many similar features which are also common to other Chinese universities. Entry to a university is determined as a result of a nation-wide competitive examination. There are no fees, and about 60 per cent of the students receive stipends. Payment of a stipend appears to be determined by the financial resources of the student and his parents. The stipend is only small—an average of 12 yuan (about £2) a month—but was said to be sufficient for board and lodging in the hostels in which the students live. A certain number of adult students, who have entered the universities by other routes, receive special stipends of 30 yuan a month, while research students receive between 20 and 30 yuan a month.

Salaries of university staffs vary from 60–90 yuan a month for assistant lecturers, 90–150 for lecturers and 150–200 yuan a month for associate professors and professors. At the Oil Technology Institute of Tsinhua University the numbers of staff in these three categories were 212, 70 and 38, and we were told this was a typical distribution among the different grades.

According to our informants, the basic cost of food for a man, his wife and two children is about 50 yuan a month, while rent of an apartment, together with water and electricity, may require an additional 10 yuan a month. University salaries appear modest if one relates them to the current exchange-rate (6·8 yuan to the pound); but in terms of purchasing power it seemed, from personal observation, that the yuan was much undervalued in relation to the pound. University salaries are being steadily increased—by about 30 per cent during the present five-year plan.

I was particularly interested in the methods of training of physicists, of whom the University of Peking is at present training about two hundred every year, after a four-year course. The whole training of physicists throughout the country is, however, being reorganized, and a five-year course is being introduced, based on a system that has been in use in the Soviet Union for some time, but adapted to Chinese traditions. Within the next few years, the annual entry of physics students to the University of Peking will increase to four hundred, and they will each do a five-year course. At the conclusion of the twelve-year plan, the universities of China will be training seven thousand physicists a year, all of whom are to have completed this five-year course.

With such an ambitious training programme, one might think that the standard of the courses would suffer; but there seemed no evidence of this at the universities visited. The standard now reached in the final year of the four-year course appears to be similar to that of special-degree students in their final year in Great Britain. When the fifth year is introduced, the standard attained will be considerably in advance of

Table 1. Hours per Week devoted to Different Subjects during the Five-year Physics Course

* The eighth semester is of twelve weeks duration only. For six weeks at the end of this semester students do workshop practice and other technical work in factories or institutes.

† During the tenth semester the whole time is spent on practical work for the thesis topic.

‡ Courses on the following special topics are offered at the University of Peking: theoretical physics, electronics, optics and spectroscopy, solid state physics, history of physics.

that reached by British first-degree honours students. In their final year, the students are required to carry out advanced practical work of a semi-research nature, and to write a dissertation. Some of this practical work being carried out in Peking included a number of studies on the Hall effect, magnetic domains, the measurement of the refractive index of gases using an interferometer method, the study of beta-ray spectra using a cloud chamber with magnetic field, and several X-ray crystallographic studies. One of the final-year theoretical physics students said he had just written his dissertation on the influence of detailed well-shape in the 'cloudy crystal' nuclear model.

The curriculum of the proposed five-year course is set out in Table 1. Each year is divided into two semesters of eighteen weeks and seventeen weeks duration, respectively, and the table shows the time devoted to the study of various subjects.

An impressive feature of the instructional system is the care taken of the student as an individual. During the first two or three years of his course, a member of staff acts as tutor to a student, guides him in his course and has the task of teaching him how to study. The supervisor must also ensure that no student spends more than fifty-four hours a week in all studies, including home study. In the fourth and fifth years, the students are organized into groups, under a student group-leader.

From the third year onwards, 'term papers' are set which involve the preparation of answers based on the reading of original papers, and the student is expected to spend about twenty-four hours in each semester working on them. In this way, experience is gained in the use of reference libraries, and the student, by the time his fifth year is reached, should be in a position to work on the problem set for his thesis.

Great care is devoted to the examination of students. All university examinations, including the final, are oral. Each year, three weeks in the first semester, and four weeks in the second, are devoted to oral examining of students. Just prior to the examination, the student draws a number of questions he will be expected to answer from a hat. He then has half-an-hour in which to collect his thoughts and consult references before presenting himself for the actual examination, which is carried out by the teacher who took the course and which may last 20–25 min. This system, which closely follows the procedure long in use in Soviet universities, appears to be working quite satisfactorily. More than 80 per cent of all students examined receive the classification 'excellent' or 'very good'. At the end of his course the student is required to defend his thesis at an oral examination.

This examining imposes a considerable burden on the teaching staff; indeed, owing to the shortage of teachers, those able to teach have had to do so for much longer hours than is desirable. The supply of good university teachers is one of the most difficult problems that is being faced. Now that the first generation of students is graduating, however, some of whom will be offered university teaching posts, it is expected that the strain of excessive teaching will be greatly reduced. Indeed, university teachers have been promised that in future it will be regarded as normal for 25 per cent of their working time to be spent on teaching, the remainder being devoted to research.

Some research in solid-state physics and in crystallography was being carried out at the universities visited; but in this connexion, our visit to the Nuclear Physics Section of the Physics Institute of the Academia Sinica was of greater interest. Although it has been operating for only a few years, it has a staff of more than a hundred scientists and technicians, and work was proceeding with the development of most of the modern techniques used in nuclear physics. There was, for example, a cloud chamber, of diameter approximately 25 cm. with a magnetic field of 10,000 gauss, and a multiplate chamber 50 cm. square which had been operated for two years at mountain altitudes. About 50,000 pictures had been taken with it, and some examples of associated production of hyperons and K-mesons, as well as other interesting events obtained. The quality of the work was impressive.

A pressurized Van de Graaff machine, together with acceleration tube to yield particles of energy 2 MeV., has been constructed, together with a high-tension generator employing a Cockcroft–Walton circuit. For work on beta-ray spectroscopy, a two-lens spectrometer has been constructed. A large group was working on problems of the production and use of scintillation counters, while another group was using nuclear emulsions which they themselves had made. Although not as good as the Ilford Company's electron-sensitive emulsions, plates had already been produced which were able to detect particles of twice minimum ionization.

Many of the present workers at the Institute have been trained in Europe or the United States and are well informed about new developments. But more physicists are greatly needed at the Institute and throughout the country. It says something for the insistence on quality of training that, faced with this position, resort has not been made to dilution of courses; and in the research work in nuclear physics, too, great stress is being placed on building a sure and solid foundation so that eventually one may expect work of the highest quality to issue from the Institute.

The scientific problems of China are immense. But they are being approached with such energy and intelligence that there seems little doubt that the China of the future will have much to contribute to world science.

STUDY OF FERTILITY

THE seventh annual conference of the Society for the Study of Fertility was held during June 14–15 at the meeting house of the Zoological Society of London and at the National Institute for Medical Research. Eighteen papers were read, and nine of these dealt chiefly with clinical aspects of human infertility. The remaining nine papers were of more general scientific interest and were communicated by the following investigators.

Dr. J. W. Goldzieher (San Antonio, Texas) described recent work on stallion semen at the South-west Foundation for Research and Education, in which it was found that the semen from some infertile stallions contained apparently normal spermatozoa. Further investigation showed that the motility and fertility of spermatozoa depended as much upon properties of the seminal plasma as upon the vitality of the spermatozoa themselves, and that the quality of the plasma varied greatly between different animals. This was demonstrated by separating the cells from the plasma by centrifugation and then suspending the spermatozoa from one stallion in the plasma from other stallions. Seminal plasma from some animals supported motility better than that from others, and this property was inversely related to the concentration of sulphydryl compounds. The incidence of pregnancy also was inversely related to the concentration of these substances in the semen.

Dr. J. Hammond (Cambridge) reported investigations on the degeneration of fœtuses during the later stages of pregnancy in the rabbit. The occurrence of fœtal atrophy and the proportion of fœtuses lost were evidently related to a maternal character that could be selected for by appropriate breeding experiments. The inheritance of the character took place in the manner of a genetic recessive and found more obvious expression in animals in which larger numbers of eggs were shed. There was evidence for the operation of the same mechanism in sheep when the number of eggs shed was increased by the administration of hormones. Dr. Hammond believes that fœtal atrophy is not a reflexion of limited space within the uterus but can be ascribed to the relative deficiency in the uterus of some substance required for normal fœtal development. The nature of the substance is as yet unknown.

Dr. A. Walton (Cambridge) described an apparatus developed in collaboration with Mr. H. M. Dott wherein a semen sample is held within a 'Cellophane' tube around which an artificial medium can be circulated. The properties of the medium can be varied at will so that the influence upon the spermatozoa of temperature, hydrogen-ion concentration, gas tension and diffusible substances can be studied without the need for dilution of the spermatozoon suspension directly with the artificial medium. When spermatozoa derived from the epididymis were placed in the apparatus, it was possible to show that the initiation of motility was due to the presence of both oxygen and fructose in the surrounding medium. The effect of the accessory secretions could be ascribed to their content of these substances. Nitrogen inhibited the motility and this inhibition could later be reversed by supplying oxygen.

Dr. I. G. White (Sydney) gave an account of investigations on the effect on spermatozoon motility of composition of the medium, concentration of spermatozoa, and temperature. The buffering of diluting media was particularly important under anaerobic conditions owing to the production of lactic acid. The output of lactic acid varied with the amount of phosphate present, because high concentrations of phosphate decreased the ability of the spermatozoon to oxidize lactic acid. Potassium tended to improve motility, and traces of copper and iron were probably not detrimental. Most chelating agents tested were toxic; cobalt decreased the toxicity of some. The 'dilution effect' was referable to the loss of substances from the spermatozoon, and these may include biotin and cytochrome *c*. The presence of lipo-protein in egg-yolk mitigates the loss. 'Cold-shock' was associated with a drop in the adenosine triphosphate content of the spermatozoon. Some protection was afforded by egg-yolk owing probably to the presence of lecithin and similar compounds. Antibiotics were in general well tolerated by spermatozoa. When spermatozoa were rewarmed after deep-freezing, some metabolism of the added glycerol occurred under anaerobic conditions. Ram semen contains 1 or 2 per cent of glycero-phosphatyl choline.

Miss Clare Harvey (Exeter) said that detailed and systematic examinations of early and late fractions of human semen showed that the early fraction, though often very small, contains the majority of the spermatozoa. She believes that in the pre-ejaculatory phase of excitement a dense mass of fresh spermatozoa passes into the vas deferens and ampulla, where it is met by back-flowing prostatic secretion. The seminal vesicles then discharge, washing the rest of the spermatozoa through the ejaculatory duct. The function of prostatic citric acid in man may be to inhibit coagulation and permit the ready escape of spermatozoa in the female tract, and the function of coagulation in the late fraction may be to prevent dilution of the early fraction.

Mr. G. A. Harrison (Liverpool) reported that mice kept in a hot environment (dry bulb 90° F., wet bulb 84° F.) bred normally; but the females failed to suckle unless they had been brought up under the same conditions. There was thus evidence of adaptation to the high temperature. Adapted animals also survived longer when exposed to temperatures (dry bulb 104° F., wet bulb 84° F.) that generally proved fatal in about 12 hr. Survivors from such an experiment also showed no loss of fertility. Rats exposed to a dry-bulb temperature of 100° F. suffered little or no damage to the testis. When water at 107° F. was applied to the scrotum the testis temperature became constant at 103° F. An environmental temperature of 107° F., however, did not raise the testis temperature above 96° F., although the abdominal temperature was 102° F. The scrotum is therefore an important and efficient heat-disposing surface. This property was removed by covering the scrotum with paint, whereupon an environmental temperature of 100° F. led to testicular damage.

Mr. J. H. Grant (Liverpool) said that he had studied the effects on the remaining testis of unilateral castration in rats. Following the operation, there was a compensatory increase in the growth-rate of the testis, and the final volume reached was greatly in excess of normal. The total number of tubule cells, however, was not increased, nor was the amount of interstitial tissue. The ratio of the diameter of the lumen to the diameter of the whole tubule was also unchanged. The larger size reached by the testis is therefore imputed chiefly to hypertrophy of the tubule cells, although the Leydig cells, after an early decrease, did show some increase in number. Testosterone administration was found to inhibit the testis hypertrophy if applied in the first five weeks after the operation.

Prof. R. G. Harrison (Liverpool) described experiments in which solutions of chorionic gonadotrophin were injected into mature rats. In a control series, rats received injections of sterile distilled water. No effect was seen in the tubular epithelium, in the number of Leydig cells or in the amount of interstitial tissue; but there was an increase in the quantity of tissue fluid. 'Phytoid' vacuoles appeared in the spermatogonia, connoting an increase in cell fluid, and there was enlargement of spermatocyte nuclei. In addition, spermatogonia appeared to be reproducing spermatogonia in large numbers, for several layers of these cells were observed. These changes were seen in both experimental and control groups of rats and are interpreted as evidence of a stress reaction evoked by the injections.

Dr. M. W. H. Bishop (London) gave a short account, illustrated by colour transparencies, describing the application of fluorescent dyes, notably acridine orange, to the study of morphology in living spermatozoa. When the preparations are subjected to ultra-violet irradiation the spermatozoa exhibit a brilliant fluorescence, the acrosome appearing red or orange and the rest of the cell green. The large variations in the form of the acrosome in several species of mammals were thus clearly demonstrated. With the dye primuline a striking colour contrast is obtained between living and dead spermatozoa.

Demonstrations provided by the Division of Experimental Biology at the National Institute for Medical Research illustrated aspects of work on mammalian gametes and fertilization, reproduction in mice after ablation of the thyroid by iodine-131, gonadal grafts in the rat, production of aspermatogenesis in the guinea pig with testis antigen, and the effects on fœtal development of exposure of the mother to severe hypothermia. C. R. AUSTIN

EFFECT OF VARIOUS STIMULI ON TISSUES OF DIFFERENT AGES

A MEETING of the British Society for Research on Ageing was held at the Ciba Foundation, London, on June 8, and a series of papers dealing with the effects of various stimuli on tissues of various ages was read

The initial three papers were introduced by Prof. K. J. Franklin, under whose direction the work had been carried out. In the first paper, Dr. Sheila B. Carter, of the University of Bristol, dealt with the reaction of the gingival epithelium to friction in rats at different ages. She pointed out that, although some human experiments have been carried out in this field, work on animals may be more satisfactory since they may be kept on a standard diet under standard conditions and the amount of friction applied can be controlled. Dr. Carter used the merion rat (*Meriones libycus*) and three experimental groups: 5–4 months old; 9–12 months; and 14–16½ months. In all groups the gum of the diastema between incisors and molars of the right side of the upper jaw was rubbed with a brush consisting of a single nylon tuft about 4 mm. long, for one minute twice daily for 4 weeks, the other side of the jaw being left as a control. The thickness of the cornified layer was afterwards measured in histological sections of the gum. The minimum width of the epithelium and the depth of the epithelial papillæ were also measured. The brushing caused a marked though variable increase (5–280 per cent) in the thickness of the cornified layer. At the same time, the minimum width of the epithelium tended to increase though not significantly; but there was a significant increase in the depth of the epithelial papillæ. It was of interest that there was no correlation between age and any histological change.

It is hoped to extend this work to a study, in the Physiology Department of St. Bartholomew's Hospital Medical College, London, of the clinical effects of mechanical friction on the human gum, and in this connexion Dr. F. J. Aumonier gave an account of his preliminary studies of the human gum. He demonstrated a striking variability in the pattern of the epithelium in human jaws which varied enormously from one side to the other in the mouth, at various levels near the teeth and in the projections of gum between the teeth. Before these clinical studies can be commenced, therefore, a very full study will have to be carried out on the variations in average thickness of gum, minimum and total thickness of the cornified epithelium, resistance to infection, etc., of the human gum in different parts of the mouth.

Dr. Patricia Lindop, of the Nuffield Gerontological Unit at the Department of Physiology, St. Bartholomew's Hospital Medical College, described three pilot experiments used in the study of the roles of whole organs in the process of ageing. The first of these dealt with the rabbit kidney, which was studied in relation to the weight of tissue and blood content at various ages. The latter was determined by using a perfusion method—washing out red cells which had been labelled *in vitro* with radioactive phosphorus. The renal blood content was determined within an accuracy of 2 per cent, and was found to be remarkably constant for animals of the same proportionate weight of renal tissue. In the rabbit Dr. Lindop also demonstrated that there is a distinct correlation between the weight of renal tissue and the whole body weight—that is, the smaller the animal the larger is the proportion of renal tissue. The normal renal blood content shows a parallel decrease ranging from 50 per cent in the neonatal period to 41 per cent between weaning and puberty, and thereafter 31 per cent in adult life with no definite decrease even at three years.

The second experiment carried out by Dr. Lindop was a study of the uptake of radioiodine in 246 rats of different ages (1 day–47 weeks old). No significant difference in rate of uptake nor in the total amount of iodine taken up by the gland was recorded, although if older animals had been studied a change might have been found.

In the third series, eighty-five elderly patients between sixty-five and ninety-five years of age were studied in relation to their renal function following a period of hypotensive anæsthesia for prostatectomy. The aim of this study was to determine whether hypotension with vasodilatation, as occurs with vasomotor paralysis, is less harmful to the senile patient with reduced cardiac, cerebral and renal reserves than hypotension with vasoconstriction occurring during hæmorrhage at operation. It was found that a fall in blood pressure to a level of 80 mm. (of mercury) systolic was optimum. There was no impairment of renal function unless the pressure was dropped below 60 mm., when there was a transient oliguria and a rise in blood urea post-operatively.

The final paper was read by Dr. Honor B. Fell, who pointed out that early work had shown that vitamin A deficiency had caused mucous membranes to undergo a squamous metaplasia and to keratinize. Previous work by Dr. Fell and the late Sir Edward Mellanby had shown that, whereas epidermis from the trunk and limbs of 6–7-day chick embryos differentiated into squamous keratinizing epithelium in a normal medium, it formed a mucus-secreting, often ciliated, membrane when grown in medium to which excess vitamin A had been added. Dr. Fell then went on to describe experiments designed to discover whether explants of older, more highly developed, skin would undergo similar transformation in response to excess vitamin A. The scaly skin of the shank and feet of 13- to 18-day chick embryos was used.

When grown in normal medium, the 13-day skin keratinized and maintained its normal structure; but in the presence of excess vitamin A, it underwent mucous metaplasia as readily as the 7-day epidermis. The 18-day skin had a fairly thick stratum corneum when first explanted; in normal medium the keratin increased in thickness, but in the high vitamin A medium it became detached by swelling and subsequent disintegration of the upper layers of epidermal cells. The deepest, least-differentiated cells survived, and scattered excretory cells and sometimes areas of true metaplasia appeared in this region; metaplasia was less frequent and usually less extensive than in explants of 13-day skin. When transferred from high vitamin A to normal medium, both the 13- and 18-day skin eventually reverted to the squamous keratinizing type. Dr. Fell suggested that, in the organ cultures, the skin was subjected to conditions which probably could not be reproduced in the intact animal; thus experiments *in vitro* with excess vitamin A involved developmental potentialities which perhaps could not have been demonstrated *in vivo*. G. H. BOURNE

PHYSICAL STRUCTURE AND ENGINEERING PROPERTIES OF CONCRETE

T. C. POWERS, who is in charge of fundamental research on the properties of concrete at the laboratories of the American Portland Cement Association, is well known for his work in collaboration with T. L. Brownyard on the distribution of water in set cement. Taking advantage of Mr. Powers's attendance at the Stockholm Conference on Winter Concreting, the Cement and Concrete Association asked him to give a lecture to an invited audience in London on March 1 at the Institution of Civil Engineers. More than seven hundred persons attended, covering a wide range of interests in civil engineering and concrete technology. It is a tribute to Mr. Powers's skill and enthusiasm that the highly specialized subject-matter of his talk was nevertheless received with absorption by his large audience, who were obviously stimulated by the many original observations.

Mr. Powers began by narrowing the field of discussion to the paste of cement and water which binds together the sand and larger aggregate. In his view, the major properties of concrete are largely determined by the paste alone, and the over-riding factor controlling the quality of the paste is the ratio of water to cement in the original mix. As hydration of the cement proceeds, some of the water becomes chemically combined, some is adsorbed in the gel resulting from the hydration, and some remains as free water in the capillaries present in the set mass. The properties of the gel, as quoted by Mr. Powers, are: density, 2·15 gm./c.c.; porosity, 26 per cent by volume; and coefficient of permeability to water, 2×10^{-15} cm./sec. The last is a remarkable figure for a substance of 26 per cent porosity, being less than is obtained with natural rocks of only 2–3 per cent porosity.

Mr. Powers then went on to elaborate a theory which caused a considerable controversy. It is well known, he said, that Portland cement is composed principally of tricalcium silicate, dicalcium silicate and various aluminates. Cements high in tricalcium silicate hydrate more rapidly and gain strength more quickly than others. This is usually explained by the fact that the aluminates react quickly with water, followed by the tricalcium silicate, while the dicalcium silicate hydrates react only slowly. Nevertheless, the evidence shows that in practical cement there is no preferential hydration of the different minerals. The evidence is threefold: constant specific surface of the gel from 1 day to 14 years; constant heat of reaction per unit of combined water from 1 day to 14 years; constant ratio of tricalcium to dicalcium silicate, as determined by the X-ray method, from the original cement up to 28 days. Mr. Powers did not offer an alternative theory to account for the differing reactivity of cements of different mineralogical composition.

The strength of the cement paste, on Mr. Powers's theory, is determined by how much of the capillary space is filled with gel. This gel/space ratio can be calculated from the original volumes of cement and water and the degree of hydration of the cement. A good relation was shown, graphically connecting the compressive strength of neat paste and the gel/space ratio. Mr. Powers then went on to use his theory to explain the variable coefficient of thermal expansion of concrete and to consider the bulk permeability and the frost resistance of concrete; especially in dealing with the latter property, it is necessary to allow for the accidental or deliberate entrainment of air during the mixing operation.

The discussion that followed the lecture mostly centred around the question of the differential hydration of cement minerals, and it is clear that this question will exercise the minds of cement technologists for some time to come. In replying to the vote of thanks, Mr. Powers made it clear that his work is not complete and that he had offered it for discussion in the hope that any errors or weaknesses might be repaired. R. W. NURSE

MOISTURE BALANCE OF THE ATMOSPHERE

FOR his presidential address to the Royal Meteorological Society, given on April 25, Dr. R. C. Sutcliffe chose for his subject "The Moisture Balance of the Atmosphere". With so much expression of opinion, both informed and uninformed, regarding the possible effects of nuclear explosions on weather and the possibility of artificially - inducing precipitation from clouds, the subject was clearly a topical one; however, Dr. Sutcliffe, who is deputy-director of the Meteorological Office, had very little to say about the narrow 'rain-making' aspect and concentrated on presenting a broad picture of the various inter-related processes going on in the atmosphere, without an understanding of which attempts to tamper with the weather may lead to confusion and, possibly, disappointment.

After lamenting the tendency for new specialist branches of meteorology and applied meteorology to channel-off research energy from the main stream, which should be concerned with atmospheric processes as a whole and which has been very much neglected, Dr. Sutcliffe made the point that the circulation of water and water vapour in the atmosphere is but one aspect of the 'general circulation' of the air which carries it. The transport of water vapour is governed by the 'macro-dynamics'—that is to say, by the equations of fluid dynamics applicable to large-scale movements of air—though processes such as condensation and evaporation affect the application of mechanical principles by reason of alterations produced in the air-density. Precipitation, produced by the coalescence of cloud particles, also reacts back on the motion since it affects future evaporation and condensation. If there were no coalescence of cloud particles, there would be clouds everywhere and the behaviour of the atmosphere might be expected to be different in many ways.

Dr. Sutcliffe classified the macro-dynamical processes, that is, processes on the scale of weather systems, as orographic, convective and cyclonic. Cyclonic developments occur mainly in middle latitudes, and he was curious to know why they have the size they are observed to have. It was unfortunate that he could not spare time to discuss theories which purport to explain this fact. In low latitudes a slow circulation of air in the planes of the meridians (the 'Hadley' circulation) evidently plays a large part in the transport of water vapour, as it does in the transport of heat and momentum; however, we also observe relatively small but intense disturbances called tropical cyclones. Dr. Sutcliffe wondered if a type of general circulation is possible in which the tropical cyclones play a part in low latitudes similar to that played by the extra-tropical cyclones (depressions) in middle latitudes. He claimed that, with the use of some imagination, one could see indications on climatic mean charts supporting this view.

A fact of some significance concerning the relation between rainfall and other processes going on in the atmosphere is the relatively small 'capital' of water vapour in the atmosphere as compared with the 'turnover'. Dr. Sutcliffe pointed out that there is, on the average, in the whole atmosphere, a total water content equivalent to only about ten days supply of rain. It follows that the total rate of rainfall must be rather closely controlled by the total rate of evaporation. Evaporation requires not only a supply of water but also a large supply of energy, and for control of weather over longer periods we have to look to those large reservoirs of both water and thermal energy, the oceans. The amount of energy required for evaporation is actually comparable with the infra-red radiation from the Earth's surface, and this led Dr. Sutcliffe to a discussion of the rather complicated energy-budget of the atmosphere. In drawing up a balance-sheet we have to use information derived in a variety of ways, some direct and some indirect, and little of it completely reliable. We are concerned not only with evaporation and precipitation and the convective transport of heat by air motions but also with radiative transfer in both the visible and infra-red regions. Various workers have attempted to draw up such a budget; but in many cases some entry has been made which is based more or less arbitrarily and uncritically on the work of others, and sometimes it is difficult to discover by whom and on what evidence a particular estimate was originally made. Dr. Sutcliffe paid special attention to some very recent calculations by Budyko of the energy balance of the atmosphere as a whole. Finally, he produced an estimate of evaporation and precipitation over land and over sea as a function of latitude. There appears to be only a very rough agreement between the estimates produced by different people at different times.

Appropriately, in view of the close inter-relation between different processes going on in the atmosphere, Dr. Sutcliffe ended by considering the relation between the local energy balance and weather systems. Energy supply to the atmosphere is deficient in anticyclones because less latent heat of condensation is released. It seems reasonable to suppose that they act as energy 'sinks', towards which energy is transported by air motion, and a more detailed analysis might indicate that their existence actually controls the development of new motions. It is not evident that the large anticyclones need always remain, even on average, in the same places, and Dr. Sutcliffe considered it possible that the atmosphere has more than one pattern of 'general circulation'. The idea is intriguing, and it is to be hoped that it will be followed up in the series of discussions on 'general circulation' problems, which, Dr. Sutcliffe announced, is being planned by the Royal Meteorological Society. One such discussion has already been held after the presentation to the Society of a brilliant theoretical paper by Dr. N. Phillips, of Princeton (see *Nature*, July 21, p. 129). Dr. Phillips has shown that very many observed features of the behaviour of the atmosphere are reproduced in the numerical integration of the equations governing a very simple model of the atmosphere. The prospects of transforming meteorology into an exact science are very much brighter now than they have ever been in the past.

E. T. EADY

UNIVERSITIES OF GREAT BRITAIN

1955 CONFERENCE

AT the 1955 Conference of the Universities of Great Britain and Northern Ireland, held during December 16–17, a number of topics were discussed, one of which, the age-group 'bulge' and its possible effect on university policy, has been reported in these columns (*Nature*, January 21, p. 115). The full report of the Conference proceedings, which has now been published*, summarizes the speeches and discussion at this session, and also those of the two preceding sessions on, respectively, the transition from the sixth form at school to the university and the financing of research in universities by outside bodies.

The first session was opened by speeches from Mr. H. D. P. Lee, headmaster of Winchester College, Miss K. Anderson, headmistress of the North London Collegiate School, and Prof. N. F. Mott, of Cambridge. Mr. Lee, starting from the findings of the report on university entrance requirements, claimed that we must not specialize at the expense of general education and that the latter includes, first, a certain minimum of academic achievement such as a certain standard in elementary mathematical operations, a certain ability to understand and write good English and some knowledge of a foreign language, as well as, secondly, at the level of the sixth form, an awareness of the place of specialized study in the field of human knowledge as a whole. He maintained that general education could not be provided at the university itself; it must be given in the schools. Miss Anderson outlined the problems of girls' schools more particularly, and referred to the growing tendency for consultation between the schools and the universities. She suggested that the schools could do more to develop individual responsibility for work. Prof. Mott stressed the importance of framing university entrance requirements and entrance scholarships to encourage the schools to provide time in the sixth forms, along with specialization, to look at other fields of endeavour and see their relation to the main cause of study, and also the value of making it easy to change from the arts to the science side, or vice versa, later than the usual age of fourteen. In the discussion, Prof. J. L. Montrose, while welcoming much of Mr. Lee's address, dissented emphatically from the view that general education could only be given at school, suggesting that it comes late in a university career, even in postgraduate study, and in this he was supported by Dr. F. M. Brewer. Mr. S. R. Woods referred to the need for some method of assessing general education, and Dr. G. N. Burkhardt suggested that specialist study in the sixth form would be reduced if the syllabuses on which Advanced Level and Scholarship papers of the General Certificate of Education are set were reduced to two-thirds of their present size. This idea of pruning was supported by Mr. Lee and Miss Anderson; but Miss Anderson did not believe that general education could be examined.

* Report of the Proceedings of the 1955 Conference of the Universities of Great Britain and Northern Ireland. Pp. 112. (London: Association of the Universities of the British Commonwealth, 1956.) 3s. 6d.

Dr. V. E. Cosslett's paper on the financing of research in universities by outside bodies was read, in his absence through illness, by the chairman, Prof. J. L. Montrose. Basing his remarks on a recent investigation of the Association of University Teachers, Dr. Cosslett said that about 20 per cent of the research resources of university departments of science and technology are engaged on work of direct interest to industry and that about 5 per cent of university income is derived from industrial support for research. Grants from charitable foundations and learned societies provide a further 2 per cent, and research grants from government sources amount to about 7 per cent of university income. Dr. Cosslett raised the questions whether limits should be set to the amount of outside grants received by a university and to the proportion of sponsored research within this amount, and, if so, what principles should guide the universities in discriminating between grants. He suggested a limit of 50 per cent for outside grants and that not more than 50 per cent, preferably not more than 30–35 per cent, of research projects in a department should be sponsored projects.

Prof. H. W. Melville, who followed, dealt more particularly with the functions of the Department of Scientific and Industrial Research and the connexion between university scientists and government defence establishments; but he also commented on the relations with private industry, which is likely to become the largest contributor to the support of university research, and stressed the value of seconding industrial personnel to work in a university. Sir Harold Himsworth, who dealt largely with medical research, put the government contribution to university research at about £3 million, of which £1·17 million is from the Medical Research Council. He thought the device of establishing research units in association with universities has proved an elastic and effective way of dealing with special problems of common interest, but that there is a natural tendency for successful units to be taken over by university departments. Government support of research by non-academic bodies is, however, increasing and is likely to increase further. Sir William Slater was in general agreement with Sir Harold's remarks, as was Prof. A. R. J. P. Ubbelohde, who discounted some of Dr. Cosslett's statistics. Prof. N. F. Mott also did not share Dr. Cosslett's concern about support from industry, and Prof. J. A. Pope challenged the adequacy of the grants for postgraduate work by the Department of Scientific and Industrial Research.

NATIONAL FOUNDATION FOR SCIENTIFIC RESEARCH, BRUSSELS

REPORT FOR 1954–55

BESIDES the lists of recipients of grants for 1955–56 and the subjects of research, the eighteenth annual report of the National Foundation for Scientific Research, Brussels, covering the year 1954–55*, includes an inventory of microfilms and a list of publications by recipients of grants during the year under review. The Special Commission for Clinical Research received subsidies of 345,000 francs for the work at the University of Brussels on the effect of suprarenal-cortico hormones on the renal reabsorption of proteins, on the effect of suprarenal hormones on the metabolism of fructose in normal subjects, diabetics and patients suffering from hepatic deficiency, and on the inhibiting effect of plasmatic hypertony on the liberation of hormones of the suprarenal cortex provoked by a standard dose of adrenocorticotropic hormone; other work reported relates to the depressive action of cortisone on thyroid activity and to human suprarenalectomy. A grant of 350,000 francs for the State University of Ghent was for work on the influence of cortisone on the respiration of cardiac and diaphragmatic tissues, the stimulation of the suprarenal cortex by adrenocorticotropic hormone, the effects of the latter and cortisone on lipoproteins and the hydrolysis of corticoid urinary reducers. The State University of Liège received a subsidy of 520,000 francs for a comparative pharmacodynamic study of the effects on the organism of the injection of sodium salicylate and other compounds, and the Catholic University of Louvain 456,000 francs for its work on the hormonal inter-relations during gestation.

Grants to research workers for 1955–56 totalled 3,515,000 francs, while for the years 1956 and 1957 a total of 3,000,000 francs was allocated to the National Centre of Aeronautical Studies and Research. The first electronic calculating machine designed and constructed in Belgium was completed in Antwerp in February 1955. A special credit of 200,000 francs was made to enable M. Velghe to complete his astronomical work at the Boyden station of Harvard University at Bloemfontein in South Africa. Prof. M. de Hemptinne and M. Migeotte received a grant of 135,000 francs for their infra-red spectroscopical work, and Prof. J. Morelle, Ch. De Muylder and P. De Temmerman received 150,000 francs for their research on experimental coarctation and its retention and on vascular peripheral resistance.

Radioisotopes distributed in Belgium under the authority of the Foundation have been used in the following proportions: medicine, 31; industry, 25; agriculture, 6; physics, chemistry, biochemistry and applied sciences, 28; public services, 5. At the University of Brussels, the exchange of calcium between the bony tissues and the general organism has been studied in the dog with calcium-45; and the isotope phosphorus-32 has been used to study certain aspects of the dispersion of organic phosphorus compounds in the organism and their fixation on cholinesterase, the anti-cholinesterase activity in certain organo-phosphorus insecticides, including the synthesis of di*iso*propyl chlorophosphate and di*iso*propyl fluorophosphate, and the assimilation of carbon dioxide by micro-organisms by means of carbon-14 dioxide. At the University of Ghent the isotope zinc-65 has been used for establishing the distribution constants of zinc bromide in liquid–liquid extraction with diethyl ether and di*iso*propyl ether, carbon-14 has been used to study the influence of dinitro*cyclo*pentylphenol on the metabolism of alcohol in mice, and radioactive iodine has been used for studying the metabolism of iodine in infants suffering from lipoid nephrosis. At the University of Liège, carbon-14 has been utilized for preparing methyl iodide and L-methionine in studying the biological origin of the methyl group of adrenaline and of creatine; iodine-131 has been used for studying a number of toxic goitres, phosphorus-32 for studying the role of inhibitors of cholinesterase on the penetration of the phosphate ion in respiratory organs of the mussel, and carbon-14 for examining the metabolism of œstrone in the rabbit.

* Fonds National de la Recherche Scientifique. Vingt-huitième Rapport Annuel, 1954–55. Pp. 269. (Bruxelles: Fonds National de la Recherche Scientifique, 1956.)

At the University of Louvain rubidium-86 has been used in studies of the beta–gamma angular correlation of this element, carbon-14 in studies of the decomposition of organic matter in the soil, and at the Royal Military School various studies, by means of chlorine-36 and iodine-131, have been made of heterogeneous reactions in the gaseous phase. At the State Agronomic Institute at Gembloux phosphorus-32 has been used in research on its eventual toxic effect on the development of the mycelium of mushrooms and in the chemical separation of phosphorus compounds such as phospholipoids, nucleoproteins, mineral compounds soluble in water and mineral compounds soluble in acids. In clinical work, gold-198 was utilized in three cases at the Centre for Tumours and Physical Medicine, iodine-131 in the treatment of thyrotoxicosis, while in industry iridium-192, cobalt-60 and cæsium-137 have been applied in the radiography of steel and in the detection of welding faults, and thallium-204 has been used in experiments on the elimination of static charges.

THE AFRICAN WILD DOG

THE African wild dog, or hunting dog, *Lycaon pictus*, is a distinct species and is neither related to any domestic breed nor does it appear to be the forerunner of any known type of domestic dog: there are certain structural differences, such as the absence of dew-claws. According to R. M. Bere, the dogs stand about twenty-six inches at the shoulder and measure about four feet from nose to tip of bushy tail (*Oryx*, 3, No. 4; May 1956). The colour is variable, but is similar to that of a normal 'Alsatian' (German shepherd dog), the animal being covered to a greater or lesser degree with black, yellow or white blotches. A notable feature is the large upstanding, rounded ears. There are recorded cases of wild dogs having been successfully tamed; but an objectionable smell renders them somewhat unpleasant as household pets.

Wild dogs hunt in packs, killing wantonly far more than they need for food, and by methods of the utmost cruelty: *Lycaon* does not kill quickly as the lion does, but often starts to devour his antelope victim before life is extinct. They do more damage than almost any other of the Carnivorae; when they enter a particular stretch of country the disturbance they cause is so great that, for the time being, all the buck are driven out. The absence of antelope from an area is often the first sign of the wild dogs' presence. A particularly unpleasant characteristic is that they will, without hesitation, turn upon any member of the pack that falls by the way through wound or sickness and show no reluctance to consume their own kind.

When the Uganda National Parks were established it was considered necessary, as had been the case elsewhere, to shoot wild dogs in order to give the antelope opportunity to develop their optimum numbers. Fortunately, only a few wild dogs have had to be destroyed, and their number in the parks does not seem to be particularly large. Their habits do not allow them to stay for long in any one place, for they would starve if they did so: the wild dog packs create their havoc and move on.

The shooting of wild dogs has been questioned recently on the ground that, if persisted in, it would result in a disturbance of the balance of Nature. It was argued that should the antelope increase beyond a reasonable limit, the inevitable result would be starvation due to over-stocking and over-grazing. On balance it appears clear that, provided the packs do not increase beyond a reasonable size, they should not be interfered with. With wild animals generally, the rate of breeding and the percentage of those born to reach maturity is, in the absence of predators, largely controlled by the food supply. Generally speaking, the infant mortality among the Carnivorae seems relatively high, so that unless the food supply becomes abnormally easy, numbers just about maintain themselves.

THE SWEDISH FOREST SERVICE

THE forests of Sweden have played almost as important a part in Britain as in Sweden itself during the last half of the nineteenth century and the first half of the present, and it is not inappropriate, therefore, that the Swedish Forest Service should have published in English a handsome booklet on the development of the forests in relation to the Service*. It was the change in materials used for construction in Britain, especially for ships and buildings, which gave rise to a large demand for coniferous timbers, and Sweden seized the opportunity to exploit its large areas of coniferous virgin forests; until then the chief commercial home demand was for charcoal for the mineral industry. Swedish exports to Britain largely increased after the latter took off the import duty on softwoods in 1866. In fact, with its increasing industrial activity and increasing demands for pit wood for the coal mines, building timbers and paper pulp, Britain was lulled into a false sense of security; plans for starting afforestation in Britain, the subject of royal commissions, committees, etc., came to nothing, and by the end of the nineteenth century Sweden had built up a very prosperous export trade.

The early history of Swedish forests, though on a much larger scale, was similar to that of Britain to a great extent. In early times the king owned large areas, which were used for hunting purposes, and claimed all waste land. Then came a period in the

---

* The Swedish Forest Service. Pp. 44. (Stockholm: Swedish Forest Service, 1956.)

Middle Ages when the Church and the nobles owned much of the forests. At length, with the Reformation, Gustavus V confiscated all the Church property, and gradually it became the rule that all forests not in private ownership and used for the estates belonged to the State. When the foreign demand arose during the past century, the State again gave away large areas of forests to private people and timber merchants, and heavy unrestricted exploitation took place. A Forestry Institute had been founded in October 1828 by Israel Adolf von Strom, regarded as the 'father' of Swedish forestry, with the object of arousing interest in forestry throughout Sweden. The Institute became known later as the Swedish State College of Forestry, which held its centenary in 1928.

Sweden is divided for forestry purposes into three parts—northern, central and southern. The greater part of the State forests are in the north, where the soils are much poorer and, for climatic reasons as well, the growth is much slower. The Forest Service dates back to the seventeenth century, the duties then being to supervise royal hunting and to keep to the regulations as regards felling and selling forest produce by the people. In 1859 a Board of Forestry was established and six forestry schools were founded. Private forests were still outside any legislation. In 1883 the agricultural sections of State lands were placed under the Board of Forestry, and the name of the Board was changed to Board of Crown Lands and Forests. Under the Board came forests, the Forest Research Institute founded in 1902, and forest education, both higher and lower.

The most rapid progress was made in forest administration from the beginning of the century, one of the chief steps being the reorganization of the accounting system. Separate accounts officers were established in different parts of the country, and this allowed the forest officer, now relieved of much 'paper' work, to devote more time to his forests in the open, instead of chiefly in the office. The Forest Service had been a trading department, and this was changed by the formation of the Royal Swedish State Forestry Industries, Ltd., which is owned by the Forest Service; the supervision of private forests and public non-State forests was placed under a Royal Board of Private Forestry. The staff of the Forest Service is very much on the lines of that in Britain, as also is the forestry education. One difference is that a much greater latitude is given to the district forest officer, who is made responsible, within the administrative policy laid down, for all the work within his charge and has not constantly to refer to superior authority. E. P. STEBBING

THE ROSS GLACIER

By RICHARD BROWN

IN view of the forthcoming work in the areas around the antarctic during the International Geophysical Year of 1957–58, it may be appropriate to review some observations on the Ross Glacier in South Georgia, Falkland Islands Dependencies, which date back to the first International Polar Year.

The island of South Georgia, some 120 by 25 miles (the long axis lying north-west–south-east), lies some 1,000 miles east of Cape Horn, between latitudes 54° and 55° S. It is entirely mountainous, the axial chain rising to almost 10,000 ft.

The Ross Glacier (lat. 54° 33′ S., long. 36° 05′ W.) is the chief feature of Royal Bay, a large inlet on the north-east coast of the island. It presents a wide front of ice cliff approximately 120 ft. high, calving into the water at the head of the bay, and rises to a low pass (the Ross Pass) which leads downwards by equally gentle slopes on the far side as the Brogger Glacier, to meet the sea on the south-west coast, where it calves into the waters of Undine South Harbour. The distance from coast to coast is almost 15 miles.

The German Transit of Venus Expedition had its base hut and observatory on the north side of Royal Bay during the years 1882–83. The party was a very hard-working one, for, in addition to the astronomical observations, work was also carried out in the fields of geology, zoology and botany. A survey of the area was made, and plots of the position of the ice front were made on four occasions: August 1882, December 1882, May 1883 and August 1883. There was recession between these dates, particularly the last two, amounting to a total of almost half a mile[1].

The next visitor to Royal Bay was Otto Nordenskjold in 1902.

Before work in the Cumberland Bay area farther to the north, the surveyor of the Expedition, S. A. Duse, plotted the new position of the snout in April 1902. It was found that the ice-front stood in a position in advance of that of August 1882. The advance had been in excess of the total retreat noted by the German party. Nordenskjöld summarized his own and the German expedition's findings in his book "Antarctica"[2].

In December 1951 the area was visited by the South Georgia Survey, led by Duncan Carse. The true left bank of the glacier was used as a sledge route to the Ross Pass and the interior. The area was accurately mapped; but no glaciological work was undertaken[3]. In January 1955 the position of the snout was plotted by members of the British South Georgia Expedition, as part of the glaciological programme. This new position showed a large embayment near the south edge, and a considerable retreat of the north part of the snout. So far as comparison of the plans (on varying scales) permits, it would appear that the cliffs occupied a somewhat intermediate position between those of May and August 1883, and a considerable retreat from the 1902 position. On the south side of the glacier, recent moraines exist up to 600 ft. from the snout, and it may be that there was further advance after the 1902 maximum, for the 1882–83 and 1902 positions show little variation of the glacier's position on the shoreline, the main variation being in the position of the ice-cliffs in the water.

The glacier is derived from two main accumulation areas: that to the north from the peak ('Sunset Peak'; not an officially recognized name) at the south end of the Allardyce Range and the Ross Pass snowfields, and that to the south from the Salvesen Range, including a separate lobe which produces a large area of complex crevassing on the south side of the main stream of the glacier near the snout.

These two areas are of different altitude; that of the Allardyce is of a lower altitude than that of the Salvesen side by some 1,500 ft. on average.

In late January 1955 the summit of the Ross Pass (1,800 ft.) was surfaced with large irregular patches of firn, with intervening areas of bare hummocky ice. Ablation was proceeding (and continued elsewhere in the island at similar altitudes until March) and it seems likely that in some seasons at least the firn line rises above the level of the pass. This means that in some years the net accumulation of the 'Allardyce part' of the glacier will be very small, confined to the slopes of 'Sunset Peak' above approx. 2,500 ft. The Salvesen accumulation areas, being generally much higher, will not come below the firn line, and any amelioration of climate will be less immediate in its effect on the volume of ice[4]. These areas are further fed from the surrounding cirque of peaks of more than 7,000 ft., from which large amounts of ice fall as avalanches.

It is interesting to note, in connexion with the 1902 position, that the greatest advance was in that part of the ice front associated with the Salvesen accumulation areas. The phenomenon of sudden considerable advance of a glacier is further exemplified by the recent advance of the Harker Glacier in Moraine Fjord, near the administration centre at King Edward Point in Cumberland Bay. There are two glaciers calving into the fjord; the Harker is the one at the head. Photographs taken during the Shackleton Expedition of 1914 compared with those taken up to 1952 show little difference in the position of the snout[5]. At some time after early 1952 there has been an advance of considerable dimensions and the snout has moved forward over flat ground at the head of the fjord for some 300 yards, as well as occupying a more advanced position in the fjord. The nearby Hamberg Glacier has remained quiescent. The position of both these snouts was plotted in December 1954, and their proximity to the settlement makes them very suitable for observations in the future.

South Georgia lies in the unstable area of the Scotia Arc. Whether these glacial surges are derived from ice avalanches of great magnitude caused by earth tremors is not certain, although a few earthquakes have been recorded in the island[6]. Further investigation of this factor might bring to light interesting data; but it would seem, at the present, that these surges occur only when the glacier is fed from some hanging ice-fall system, as is the case in both the Harker and the 'Salvesen accumulation area' part of the Ross Glacier. Prof. A. Desio has recently described the much larger (though apparently similar in character) advance of the 'Kutiàh Glacier' in the Karakorum Himalaya[7].

Thanks are due to the Governor of the Falkland Islands and to the Falkland Islands Dependencies Survey authorities for the opportunity to carry out this and other glaciological work in South Georgia.

GROWTH AND SEXUAL MATURITY IN AQUATIC MAMMALS

By Dr. R. M. LAWS

National Institute of Oceanography, Wormley, Surrey

In mammals growth is determinate, and there is an average adult size for individual species. The rate of growth is a specific phenomenon presumably fixed by heredity, and different species grow at different rates in the same circumstances and pass at different times through similar phases of development[1].

Owing to the practical difficulties there are few records of weights of aquatic mammals, and length is generally used as a measure of size. It is also a more accurate measure, being less subject to fluctuations than is weight. The average length of the female at puberty and physical maturity is known with some accuracy for the eleven cetaceans and twelve pinnipeds listed in Table 1, being based in most cases on a large number of specimens; but the length at puberty in the male is known with less accuracy. If we convert the length of the female at puberty to a percentage of the size attained when growth ceases it is seen to be remarkably constant, averaging in cetaceans 85·1 per cent (range 80·0–88·5, $\sigma = 3{\cdot}14$, $V = 3{\cdot}69$) and 86·6 per cent in pinnipeds (range 80·8–92·3, $\sigma = 4{\cdot}10$, $V = 4{\cdot}73$). This agreement is the more remarkable when it is observed that for several of the species considered the average lengths at these epochs in the life-cycle are known only approximately. The general shape of seals and whales shows marked resemblances, being fusiform with short appendages, and the length/weight relationship is probably similar in the two groups. This would help to explain the close similarity in the percentage length at puberty in these two unrelated groups; but clearly there is a fundamental and precise connexion between growth and sexual maturity.

We have little accurate information on the rates of growth of the various species of cetaceans, chiefly because no accurate method of determining age has yet been applied. Ageing by dentine layers in the teeth shows promise[11,12], and the use of incremental layers in the ear plug of the Mysticeti is being investigated[25].

In the teeth of Pinnipedia annual dentine layers[13] or external ridges[28] have been used with some success for determining the age of specimens, and mass-growth curves can be drawn up for several species (data from refs. 13, 14, 15, 18, 19, 21, 22, 26, 27). It can be shown that for this group the percentage increment in length during the first year may be used for comparative purposes as a measure of the rate of growth. When this increment is plotted against the average age at sexual maturity (Fig. 1) they are seen to be inversely proportional. In other words, the slower-growing species take longer to attain the level of about 86 per cent of the final length and so mature later than the precocious species. Since precocity in seals affects the embryonic growth-rate, the length at birth is also a reflexion of the rate of growth and bears a similar relationship to the age at puberty. A similar rule holds for the males, though maturity tends to be attained at a later age, and owing to the great variation in growth-rates (the polygynous species have a double sigmoid curve[13,22]) the percentage length at sexual maturity is not so constant. Likewise, in the species of whales for which we have

precise information, the male attains sexual maturity at a later age than the female. The sparse evidence available suggests that in general the faster-growing species of whales are those which mature early.

Whales and seals, being aquatic mammals, are able to bear young which are very much larger, both absolutely and relatively, than the young of the large terrestrial mammals. In the bear, for example, the weight of the new-born young in relation to the mother is 1 : 600, in the lion 1 : 160 [1], whereas in the elephant seal it is of the order of 1 : 30 and in the fin whale about 1 : 17. In the elephant this ratio is about 1 : 20 but the gestation period is greatly prolonged. During pregnancy, energy is required for fœtal growth and maternal growth, and reserves must be accumulated for the lactation period. To take an extreme example, the elephant seal pup weighs about 100 lb. at birth and gains about 350 lb. in the following three weeks, while the female probably loses about 700 lb.[13]. In the female it is therefore an advantage (speaking teleologically) to have completed or almost completed growth before bearing young, as otherwise the maternal and fœtal needs would compete for nutritional requirements.

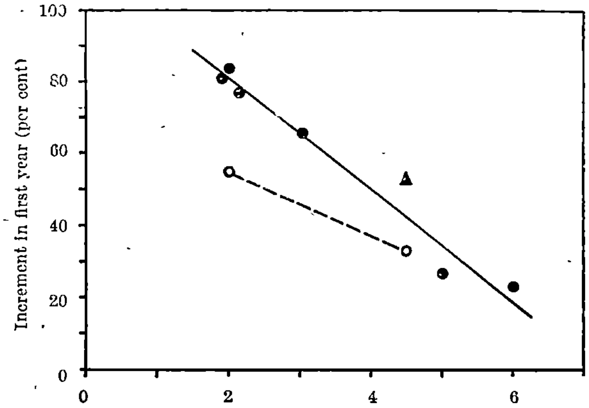

Fig. 1. Percentage increment in length during first year of life, related to age at puberty of the females of nine pinniped species: ●—●—, *Phocidae*; ▲—▲—, *Odobenus obesus* (walrus); ○—○—, *Otariidae*

If this relation between the rate of growth and the age of puberty proves to be a general rule, then it should be possible to predict the age at sexual maturity from the growth-rate, or vice versa. In the harbour seal (*P. vitulina*), for example, the length increment in the first year is about 30 per cent. This suggests that sexual maturity is attained at about 5–6 years of age instead of three years as usually given. It is more in line with the age at maturity of other members of the genus (*P. groenlandica* and *P. hispida*) and is also in closer agreement with recent population census figures for *P. vitulina*.

It would be interesting to examine the admittedly sparse data on growth-rates and relative lengths at puberty in other groups of mammals. It is possible that each group may have a specific relative size at maturity (determined perhaps by interactions between growth and gonadotrophic hormones of the anterior pituitary) of the same order as that shown to hold for whales and seals.

The nutritional level is probably the most important single variable affecting the shape of the growth curves, improved nutrition resulting in more rapid growth, especially in the younger stages. Improved nutritive conditions appear to lead to the precocious attainment of sexual maturity[29,30]. This could be a direct effect, since fertility is in general higher when food is readily available, or it might well be an indirect result of a higher level of nutrition stimulating bodily growth so that the size threshold for reproduction is reached at an earlier age.

I am indebted to Dr. F. H. Fay, Mr. A. W. Mansfield, Mr. I. A. McLaren and Dr. D. E. Sergeant for permission to use their unpublished data on pinniped growth-rates.

POLYPLOIDY IN BLUEBELLS (*ENDYMION NON-SCRIPTUS* AND *E. HISPANICUS*)

By J. YANNEY WILSON
Genetics Laboratory, Botany School, Cambridge

WITH the exception of occasional variations in heteroploid varieties of *Endymion non-scriptus* (*Scilla non-scripta*) mentioned by Darlington[1], all previous cytological studies[2-4] on this and the closely related species *E. hispanicus* (*S. hispanica*) have revealed only the diploid plant, and no record seems to have been made in the literature about polyploidy in this genus as found in the allied one, *Hyacinthus*[5].

During cyto-genetical studies on the English bluebell, *E. non-scriptus*, in three Cambridgeshire woods a number of odd 'giant' forms was noticed. When these were examined cytologically in both root-tip mitosis and pollen mother-cell meiosis, some of them were found to be still merely diploid, while others were triploid ($3n = 24$) (Fig. 1*A*). None of them has been found to be tetraploid.

In the Spanish bluebell, *E. hispanicus*, some huge forms were found in gardens, and these on similar examination proved also to be triploid ($3n = 24$) (Fig. 1*B*).

The two species have essentially the same complement of chromosomes ($2n = 16$), and attempts have been made by Sato[2] and Margherita and Maugini[4] to compare them. The former author reported that the only difference was that the satellite attached to chromosome *D* in *E. non-scriptus* was lacking in the corresponding chromosome in *E. hispanicus*; the latter authors, apart from what must be a confusion between chromosomes *B* and *C*, noticed that only one of the *D* chromosomes in *E. hispanicus* carried a satellite. My own observations show that the satellite could show all degrees of contraction and may even be torn off, so that a distinction between the chromosomes of the two species is not always possible with reference to this structure.

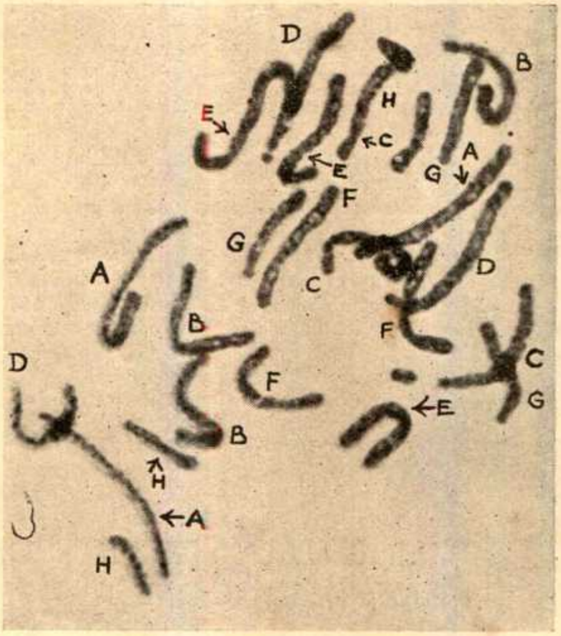

Fig. 2. Chromosomes of triploid ($3n = 24$) with characters intermediate between *E. non-scriptus* and *E. hispanicus*. Metaphase chromosomes of root-tip mitosis (× 1,500). The arrows indicate roughly the position of the centromeres, which are not shown owing to difficulty in focusing

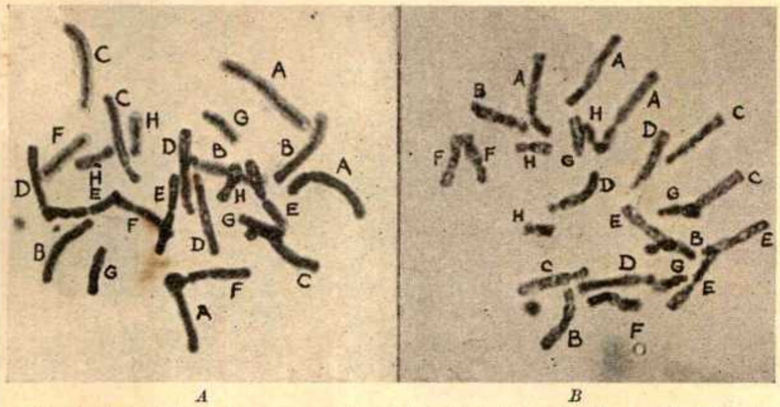
This great similarity in chromosome complement would be expected to facilitate hybridization between the two species; but strangely enough what has recently been given as 'hybrids' by de Mol van Ould Loosdrecht[6] and Turrill[7] are extraordinarily large forms. The former described a 'giant scilla' which he claimed to be a cross-bred form, while the latter has given a drawing of what he considers a hybrid that arises in gardens when the two species are together; he does not describe it, but from his drawing this 'hybrid', like that of the former author, is apparently also a 'giant', being about twice the size of the normal parental forms. These rather robust forms, apart from their huge size, really show characters that appear intermediate between the two species. Cytological examination has shown them also to be triploid ($3n = 24$) (Figs. 2 and 3*A* and *B*).



A *B*

Fig. 1. *A*, metaphase chromosomes of root-tip mitosis (treated with oxyquinoline) of triploid ($3n = 24$) *Endymion non-scriptus* (× c. 1090); *B*, metaphase chromosomes of root-tip mitosis (treated with oxyquinoline) of triploid ($3n = 24$) *E. hispanicus* (× c. 1090)

But, owing to the difficulty stated above, the possible hybrid origin of this triploid form could not be readily determined from chromosome morphology. Other cytological examinations like pairing at meiosis (Fig. 3*A*) do not

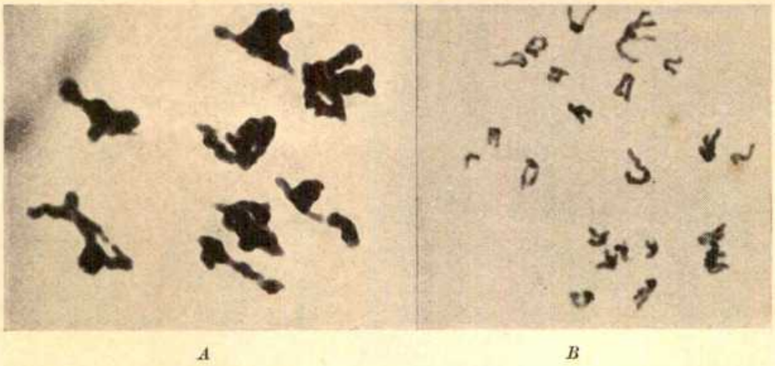


Fig. 3. *A*, same as Fig. 2. Metaphase chromosomes of pollen mother-cell meiosis showing eight trivalents (× *c.* 900); *B*, meiotic anaphase showing twenty-four chromosomes (× *c.* 540). N.B. In Figs. 1 and 2 the chromosomes are numbered according to Darlington[1]

indicate a hybrid origin, although full pairing in hybrids is unknown[5].

In many gardens there is a great variation in forms of bluebells with all gradations of characters which make them appear like 'hybrid swarms'; but unlike this triploid form, they are diploid ($2n=16$) and are in no way larger than normal. So far back as 1872, Baker[8] had described a number of such forms which Turrill[7] considers as hybrids apparently only from the morphological point of view; but without making crosses between the two species, one would require adequate cytological and other examinations to verify the hybrid origin of any of them.

It may be mentioned here that one of these diploid intermediate forms, often found in no small quantity in gardens, agrees rather well with what Baker described and assigned to *Scilla patula*; except for size this also compares favourably with this triploid form in question. Thus in view of the apparent absence of any cytological and other evidence to justify the hybridity of this, it may well be that Turrill's 'giant' hybrid is a non-hybrid triploid of this variety of bluebell.

I am indebted to Dr. H. L. K. Whitehouse for placing his garden of *E. hispanicus* at my disposal for this work.

EXPERIMENTAL INFECTION OF TURKEY POULTS WITH *EIMERIA ADENOEIDES* (MOORE AND BROWN, 1951) ISOLATED FROM A NATURAL CASE IN GREAT BRITAIN

By M. J. CLARKSON
Department of Veterinary Preventive Medicine, University of Liverpool

SEVEN species of *Eimeria* have been identified in turkeys in the United States[1]. The oocysts of three species (*E. meleagridis*, *E. gallopavonis* and *E. adenoeides*) are so similar that they cannot be distinguished from one another in the fæces of infected birds[2]. All three are localized in the terminal small intestine, cæcum and rectum, and mixed infections cannot therefore be separated into species by their distribution in the host. *E. adenoeides* is believed to be the most pathogenic, its distinguishing feature being that it undergoes development in the deep glands of the mucosa and not only in the villi.

Coccidiosis is common in turkey poults in Great Britain[3] and is believed to be due to *E. adenoeides*[4]; but this species has not to our knowledge been identified with certainty or studied as a pure infection in Great Britain. This communication reports the preliminary findings with a pure strain of *E. adenoeides* derived from a single oocyst.

Oocysts were obtained from clinical cases of coccidiosis in poults where oocyst measurements and microscopic lesions suggested *E. adenoeides* infection.

From a sample of intestinal contents from one such poult, three single oocysts, previously sporulated in 2·5 per cent potassium bichromate, were transferred by the use of a simple micromanipulator[5] to pieces of 'Cellophane' about 1 cm. square. After examination

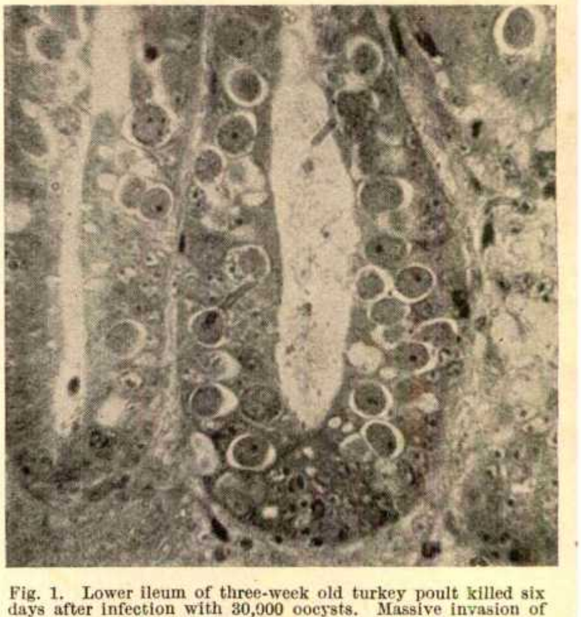

Fig. 1. Lower ileum of three-week old turkey poult killed six days after infection with 30,000 oocysts. Massive invasion of epithelial cells of deep glands by sexual stages of *E. adenoeides*. (Heidenhain's iron hæmatoxylin, × 470)

Table 1

	Site of infection	Measurements (μ)	Sporulation time (hr.)	Prepatent period (hr.)	Refractile body	Pathogenicity
E. adenoeides Moore and Brown, 1951	Lower ileum, cæca and rectum Deep glands as well as villi	Length 18·95–31·26 Width 12·60–20·94 Average 25·60 × 16·59 Ratio length : width 1·54 : 1	24	112 (approx.)	Present	+ +
Strain *A*	Lower ileum, cæca and rectum Deep glands as well as villi (Fig. 1)	(150 oocysts) Average length 25·68 Standard deviation 1·81 Average width 16·25 Standard deviation 1·21 Ratio length : width 1·58 : 1	24	120 (approx.)	Present	+

under the microscope, each was transferred to a gelatine capsule, and inserted into the crop of a fourteen-day old turkey poult which had failed to show oocysts in its fæces by a sugar flotation technique when examined daily since hatching. This procedure was repeated with three single oocysts from a natural case of coccidiosis in another flock. To prevent extraneous infection, the most stringent precautions were taken, such as heat sterilization of apparatus, utensils and cages, the use of a small isolation room which was disinfected with gaseous ammonia, and the changing of clothing and boots on entering this room. Six control birds of the same hatch, in the same room and given the same food and water, failed to show oocysts in the fæces, which suggests that the precautions taken were adequate.

Two birds, one from each group of three, became infected, oocysts being first detected in the fæces on the sixth day. Fæces were collected separately for the next 72 hr., and the oocysts sporulated. The material from one contained a total of some 150,000 oocysts (strain *A*), of which 95 per cent sporulated after 24 hr. in 2·5 per cent bichromate at 26° C. This material has been used for further work; material from the other infected bird will be studied later to see whether it is the same species as strain *A*.

Each of five coccidia-free poults, given 10,000–30,000 oocysts of strain *A*, showed oocysts in the fæces five days later. Further experiments with the large stock of sporulated oocysts derived from the original single oocyst showed that this species possessed the characteristics indicated in Table 1.

These characteristics agree closely with those given by Moore and Brown[2], and identify the coccidium as *E. adenoeides*. It will be seen that the only differences were a slightly longer prepatent period and a lower pathogenicity. Moore and Brown refer to 100 per cent mortality in birds up to five weeks of age, whereas using only a small number of birds we have had no mortality, though the poults refused all food and passed blood and cæcal plugs in their droppings. Further confirmatory tests as to specificity will be made later by immunity studies.

The relative ease of obtaining single oocysts with a simple micromanipulator which can be constructed in a few minutes, the success that followed the administration of single oocysts to poults, and the identification of the species as *E. adenoeides* suggest that the use of this technique may enable the species of *Eimeria* that occur in turkeys in Great Britain to be identified, and their relative importance in causing outbreaks of coccidiosis in poults to be determined. A study of the life-cycle of *E. adenoeides* is now in progress.

This work is being conducted with the help of a grant from the Agricultural Research Council.

FLOW OF GASES THROUGH PACKED BED OF SILICA POWDER AT LOW PRESSURES

By A. G. MONROE and D. I. GAFFEE

British Oxygen Co., Ltd., Deer Park Road, London, S.W.19

THE relationship between the permeability of a packed bed and the pressure of the flowing gas is linear at low flow-rates of gas. It has been observed that in the case of flow through capillaries at low pressures, say, smaller than 1 mm. mercury, the gas flow-rate assumes a minimum value and then rises to a limiting value at zero pressure (Knudsen, Gaede and Smoluchowski), which was found to be higher than the value expected from the slope of the line.

In the low-pressure region, where the mean free path is larger than the average diameter of the capillary, both the molecular and surface diffusion flows are responsible for the existence of the minimum in the flow-rate. The absence of such a minimum in the case of flow through powders was said to be characteristic[1], the reason being that all types of flow, molecular and surface diffusion, can occur simultaneously in pores of various diameter and thus obscure the individual types of flow[2].

The change of slope has been found to occur at pressures where the length of the mean free path approached the diameter of the voids[3].

In our work, permeation through a bed of fine silica powder at the lower range of pressures, particularly 0–10 microns mercury, was studied, at low flow-rates and ambient temperature. When considering the resistance to flow offered by a powder it is convenient to use the term specific conductance K which, in effect, is the conductance of 1 c.c. of the powder

$$K = \frac{CL}{At} \quad (\text{cm.}^2/\text{sec.})$$

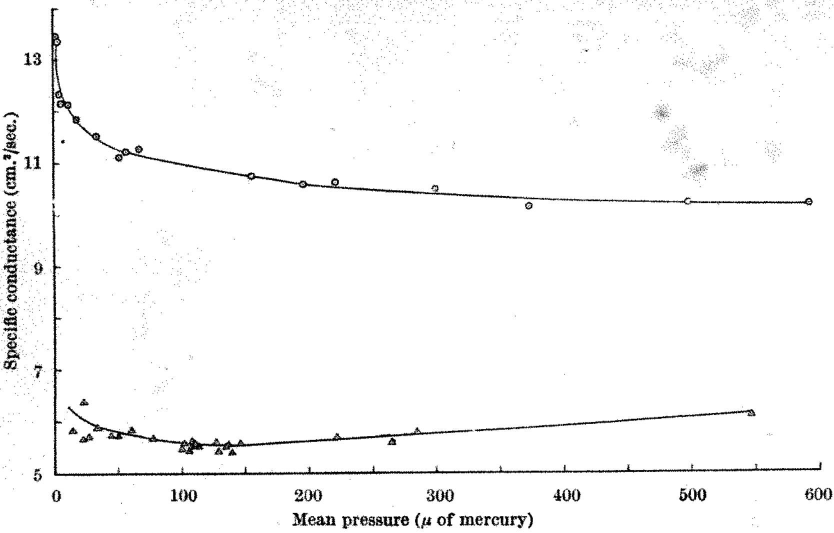

Fig. 1. ○—○—, Air (carbon dioxide-free); △—△—, 'Freon' (commercial purity)

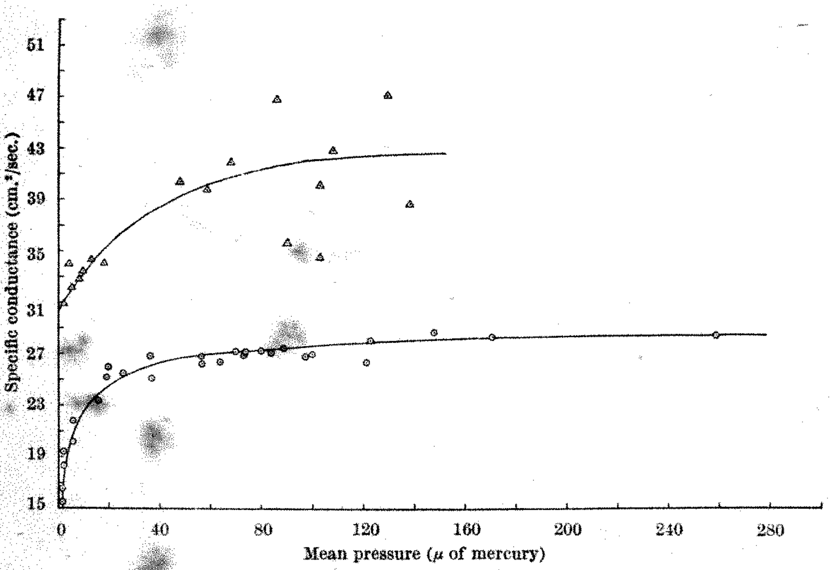

Fig. 2. △—△—, Hydrogen (oxygen-free); ○—○—, helium (spectroscopic purity)

where C is flow-rate/pressure drop; L is bed-length; A is bed cross-section area; t is time.

The specific conductance investigated in this work varied from 5 to 50 cm.²/sec. Four gases were investigated, namely, hydrogen, helium, air and difluorodichloromethane ('Freon') vapour, in order to cover a wide range of densities. The purity of hydrogen was 99·95 per cent; helium was spectroscopically pure, the total amount of impurities being not more than 8 p.p.m.; air was free of carbon dioxide and dry, the amount of water being less than 1 p.p.m., and 'Freon' was of commercial purity 99·99 per cent CF_2Cl_2.

The silica powder used in our experiments had a grain size of the order of 4×10^{-6} cm. and specific surface area of 100 sq. m. per gm., thus falling in the category of adsorbents. Pressure-drop was measured with a precise differential manometer described elsewhere[4] and gas-flow by a flow meter developed specially for the very low flow-rates.

The results presented in Figs. 1 and 2 show that the relationship between the specific conductance and gas pressure maintains its linearity to a certain low value of pressure, below which further trends are not uniform by any means. The two heavier gases, 'Freon' and air, show increase in specific conductance at zero pressure, while the lighter ones, helium and hydrogen, show the opposite. It is thus apparent that there is present a new mechanism of flow which, so far as the experimental evidence has shown, is related only to molecular weight of the gas and not to its mean free path.

It is expected that surface adsorption plays a part in the transport of molecules across the silica bed. The mobility of molecules adsorbed on a solid surface is now generally recognized[5] as against rigid concentration of sorbate on fixed sites which amounts to chemisorption. Surface diffusion is responsible for the free thermal motion of molecules adsorbed on the solid surface.

This should be distinguished from 'interstitial diffusion' encountered when a gas is sorbed by a medium, the pore diameters of which are comparable with the sizes of the molecules, for example, dehydrated zeolites[6]. It is thus not possible to speak with certainty of 'adsorption' or of 'internal surface' when the state of the molecules is more akin to solid solution than to pure adsorption. The kinetics of interstitial adsorption are governed primarily by the variations of molecular size, and in some cases it is possible to arrange molecular sieves which would allow for permeation of molecules below certain sizes.

In contrast to both Knudsen and interstitial diffusion, surface diffusion tends to be more marked in the case of larger and heavier molecules. Gas flow through micropores takes place by molecular streaming through the gas space. When using a very fine powder and condensable gases or vapours, surface flow is also expected to take place. As a result of it, the rate of flow is enhanced, that is, surface flow takes place in parallel with the flow in the gaseous phase.

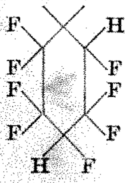
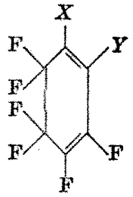
Hexafluorobenzene

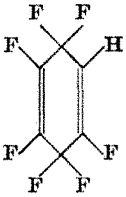
THE application of gas–liquid partition chromatography to organic fluorine chemistry[1,2] has enabled us to extend our studies on dehydrofluorination to a nonafluoro*cyclo*hexane (I) (b.p. 92°) which has been obtained[3,4] by passage of benzene vapour over cobaltic fluoride at about 150°. With concentrated aqueous potassium hydroxide, this polyfluoride (I) gave a complex mixture (b.p. 60–90°) which was shown by analytical gas-chromatography to contain nine individual components. These were separated by use of the preparative-scale gas chromatographic column, and the structures of some of them have been determined by spectroscopic examination, oxidative degradation, addition reactions, etc.



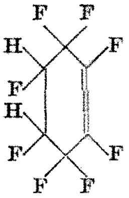
(I)



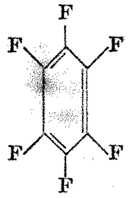
(II) X=H, Y=F
(III) X=F, Y=H



(IV)



(V)



(VI)

Two heptafluoro*cyclo*hexa-1 : 3-dienes (II) (III), a heptafluoro*cyclo*hexa-1 : 4-diene (IV), and an octafluoro*cyclo*hexene (V) were thereby identified. Also, as one of the major products, the important fluorocarbon hexafluorobenzene (VI) was isolated and characterized. The great value of the gas-chromatographic technique in effecting the separations, on a relatively small scale, of complex mixtures such as this is readily apparent. Hexafluorobenzene was prepared in amounts sufficient to carry out a preliminary study, and we have shown that chlorine will add to the ring system to give hexachlorohexafluoro*cyclo*hexane, and that attack by nucleophilic reagents is relatively easy. Thus, with methanolic sodium methoxide, pentafluoroanisole and a tetrafluorodimethoxybenzene were given. These reactions are being actively pursued at present, for a wide field of investigation has been opened up.

The nonafluoro*cyclo*hexane precursor is shown by the products II–VI to be a 1H : 2H : 4H-compound (I). The isolation of hexafluorobenzene upon dehydrofluorination suggests that the hydrogens on carbons 1 and 2 are both axial. Since *trans*-elimination of hydrogen fluoride between these two >CHF groups cannot then occur, the more difficult 'outwards' elimination, with fluorine being lost from the —CF_2— groups, can operate. Similar conclusions apply to the 1H : 2H-decafluoro*cyclo*hexanes, where the *cis*-compound gives exclusively 1H-nonafluoro*cyclo*hexene on dehydrofluorination[5], but the *trans* gives, besides this, some octafluoro*cyclo*hexa-1 : 3-diene[4].

Hexafluorobenzene has been reported before. McBee, Lindgren and Ligett[6] made it from hexachlorobenzene; their product was probably slightly impure and no reactions were given. Désirant[7] claimed to have obtained it by pyrolysis of tribromofluoromethane; but no experimental details were reported.

Experimental. 1H : 2H : 4H-*Nonafluoro*cyclo*hexane*. Benzene was passed in the vapour phase over cobaltic fluoride in a stirred reaction vessel at 150°. The reactor and the conditions described earlier[3] have been improved[4] to give increased yields of polyfluorides with no benzene remaining. Further fractionation, controlled by gas-phase chromatography, of the material having b.p. > 87° gave 1H : 2H : 4H-*nonafluoro*cyclo*hexane*, b.p. 92·0–92·5°, m.p. 44–46°, n^{45} 1·3016 (found: C, 29·2; H, 1·2. $C_6H_3F_9$ requires C, 29·3; H, 1·2 per cent). Yields were 10–15 per cent of the original polyfluoride mixture.

Hexafluorobenzene. The trihydro-compound (50 gm.), potassium hydroxide (85 gm.) and water (250 c.c.) were refluxed together until analytical gas-chromatographic examination showed a large peak due to the desired compound (17 hr.). The organic layer was separated, dried (magnesium sulphate), distilled, and subjected to gas-chromatographic separation. The hexafluorobenzene (5·0 gm.) had b.p. 80°, n_D^{18} 1·3746 (found: C, 38·6; F, 62·0. Calc. for C_6F_6: C, 38·7; F, 61·3 per cent). McBee *et al.*[6] gave b.p. 81–82°, n_D^{20} 1·3760, and Désirant[7] b.p. 80·5°, n_D^{20} 1·3777. Infra-red spectroscopic measurements (on the pure liquid) showed three bands at 1,702, 1,761 and 1,802 cm.$^{-1}$. A band was found in the ultra-violet at λ 2300 A., ε approx. 770 with an inflexion at λ 2500–2550 A. (c, 0·11 gm./l. in ethyl alcohol).

Reactions of hexafluorobenzene. (*a*) *Chlorine addition.* Chlorine (1·2 gm.) and the compound (1·0 gm.) were sealed together in a hard glass tube which was irradiated with ultra-violet light for 48 hr. The product was washed (aqueous sodium metabisulphite), dried (P_2O_5) and distilled to give *hexachlorohexafluoro*cyclo*hexane* (1·24 gm.), b.p. 137°/30 mm., m.p. 101–102° (found: F, 28·8. $C_6Cl_6F_6$ requires F, 28·6 per cent). This compound showed no absorption in the infra-red due to unsaturation over the range 1,890–1,580 cm.$^{-1}$.

(*b*) *Action of sodium methoxide.* Hexafluorobenzene (4·8 gm.) was refluxed with methanolic sodium methoxide (40 c.c.; 1 N) for 1 hr. The mixture was poured into water and the product extracted with ether. The extracts were washed, dried (magnesium sulphate), and evaporated and the residue distilled to give two fractions: (i) b.p. 145–160° (2·9 gm.) and (ii) b.p. 160–180° (0·7 gm.). Fraction (i) was re-distilled to give *pentafluoroanisole*, b.p. 155–157°, n_D^{18} 1·417 (found: C, 42·5; H, 1·8. $C_7H_3F_5O$ requires C, 42·4; H, 1·5 per cent). Fraction (ii) on being kept deposited crystals which were recrystallized from aqueous ethanol to give a *tetrafluorodimethoxybenzene* (0·15 gm.), m.p. 51·5–52·5° (found: C, 46·0;

H, 3·1. $C_8H_6O_2F_4$ requires C, 45·7; H, 2·9 per cent).

Organophilic Montmorillonite Gels

INFRA-RED absorbance measurements on hydrocarbon gels of dimethyl dioctadecyl ammonium montmorillonite[1] indicate that polymeric-type hydrogen bonding is significant in systems containing this clay mineral derivative. For example, Fig. 1 shows free hydroxyl and bonded hydroxyl absorbances in the 3-micron region for a 20 per cent dispersion of dimethyl dioctadecyl ammonium montmorillonite in a mixture containing 75 per cent cumene and 25 per cent cetane.

We suggest as one possible gelation mechanism that water, present in small amounts in the organophilic clay, forms bridges which hold montmorillonite platelets together, causing a network that leads to gel formation. This explanation appears to account for the unusual properties of these systems. Thus, they are affected by dehydration and, after standing in a desiccator, they are converted by working from gels to viscous liquids. If they are then put into another container over water, they recover their gel status as water vapour is absorbed. These gels lose consistency, as working causes montmorillonite platelets to approach parallel positions. This is apparently because bridging through the solvated layer of organic material is more difficult in the tactoid arrangement which results from working.

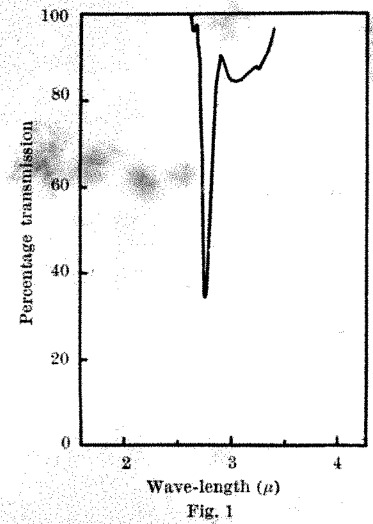

Fig. 1

But the turbulence which accompanies treatment in a sonic generator, colloid mill, paint mill or homogenizer causes platelet edges to force through the solvated layer of other platelets and make bonding contact with the underlying silicate portion of these, thus stiffening the network and explaining the increase in consistency which accompanies such treatment. At high temperatures (>150° C.), a rather firm network can form, apparently because thermal turbulence and loss of solvation in the organic layer permit a closer approach of the inorganic core of particles. This explains the unusual effect observed, that a system in the viscous liquid state changes to a gel when heated. Less water is required for network formation at these higher temperatures, and possibly no water at all, since the approach of the inorganic parts of different platelets may be so close that attractive forces between aluminium ions at the edges of the octahedral layers and negative spots on the faces of other platelets may be large enough to account for network formation.

An Ambiguity in the Variable-Solvent Solubility Test: Homogeneity of β_1-Lactoglobulin

IN the variable-solvent solubility test (see, for example, Falconer and Taylor[1], Derrien[2], Smithies[3]) a constant amount of protein is brought to a series of different concentrations of a salt, the volume, *p*H and temperature being constant. The equilibrium concentration of protein remaining in solution is then plotted against the concentration of salt. A single protein is expected to give a curve like that in Fig. 1. Here *AB* represents the exponential solubility relationship of the protein[4]. Under conditions represented by the horizontal part *PQ* of the curve (the position of which depends on the amount of protein and

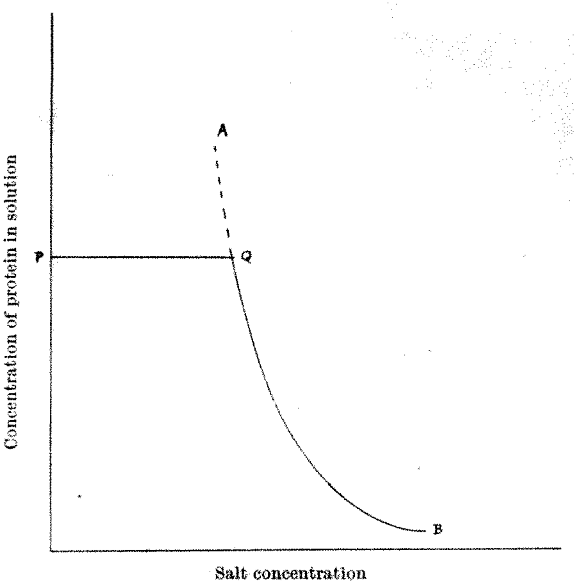

Fig. 1

the volume chosen) all the protein remains in solution; solid phase first appears at Q where PQ cuts AB, and from this point the curve follows AB as the concentration of salt is increased.

The occurrence of more than one discontinuity is normally interpreted as showing the presence of more than one protein in solution. The case of two proteins, which do not interact in solution or in the solid phase, is illustrated in Fig. 2. Each protein has its own solubility curve A_1B_1 and A_2B_2. A_sB_s, the sum of A_1B_1 and A_2B_2, is the combined solubility curve when both solid phases are present. If, for example, the proportions of proteins 1 and 2 in a mixture are as 1 : 2 (P_1, P_2 total concentration P_s), then each protein is independently salted out along $P_1Q_1B_1$ and $P_2Q_2B_2$. The combined curve is the sum of these, namely, $P_sQ_sR_sB_s$, Q_s corresponding to Q_1 and R_s to Q_2. If the amount of protein P_s is changed to P'_s or P''_s, leaving the proportions of 1 and 2 unchanged, curves $P'_sQ'_sR'_sB_s$, $P''_sQ''_sR''_sB_s$ are obtained. Two important characteristics of these curves should be noticed: (i) if Q_1 and Q_2 should happen to have the same abscissa value, then Q_s and R_s coincide; but it is very unlikely that this will happen for all values of P_s; (ii) the position of R_s on A_sB_s changes as P_s is changed.

The occurrence of more than one discontinuity in the salting-out curve may, however, result from a quite different situation, namely, when a single protein in solution is in equilibrium with different solid phases, according to the concentration of salt.

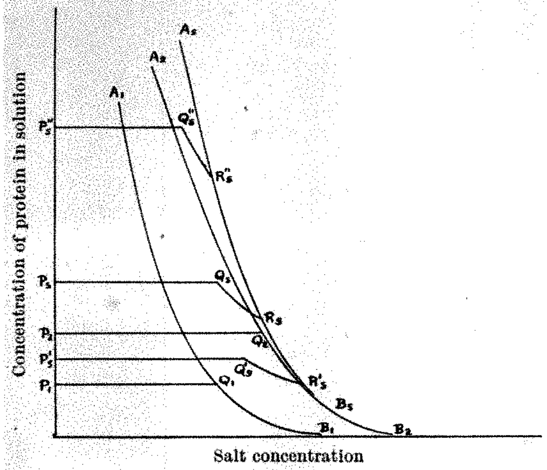

Fig. 2

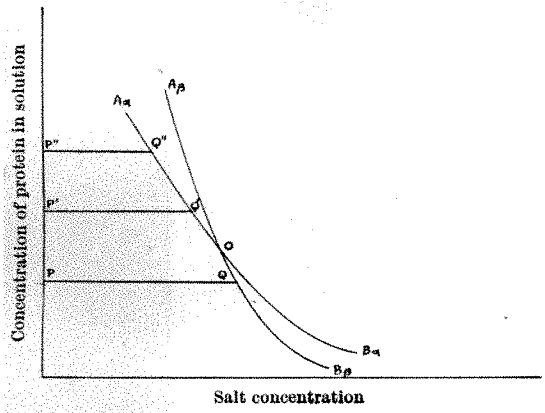

Fig. 3

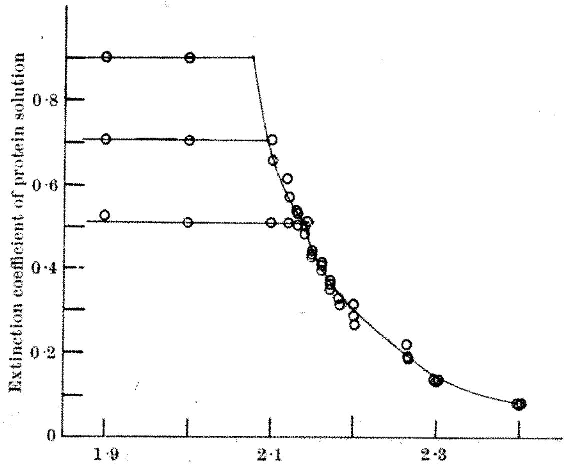

Fig. 4. β_1-lactoglobulin, pH 5·0, 25° C., 0·2 M sodium chloride, 0·2 M acetate–acetic acid buffer

Fig. 3 illustrates this case for two solid phases α and β which have solubility curves $A_\alpha B_\alpha$ and $A_\beta B_\beta$. To the right of the transition point O, β is the stable solid phase; to the left of O, α is stable. If the amount of protein is chosen so that PQ cuts $A_\alpha OB_\beta$ below O, there is only a single discontinuity q; but at higher values of P, curves $P'Q'OB_\beta$, $P''Q''OB_\beta$ are obtained, each having two discontinuities at Q' or Q'' and at O.

It would be wrong to interpret the curves of Fig. 3 as proving the presence of two protein components in solution. Fortunately, distinction between the two cases is easy. For, if the amount of protein used is changed, the position of O is unaffected, whereas that of R_s moves. It is therefore desirable that experiments of this sort should be done with at least two different amounts of protein.

Fig. 4 shows preliminary results obtained with β_1-lactoglobulin[5], which indicate that solutions of this protein contain only a single chemical component in equilibrium with two different solid phases, according to the salt concentration; similar results have been obtained with β_2-lactoglobulin.

This work was aided by a grant from the Agricultural Research Council.

A Critical Technique for Enzyme Cytochemistry

THE accurate localization of an enzyme at the cellular level by a cytochemical technique requires a full investigation of artefacts due to diffusion of enzyme, reagents and reaction products. The classical superimposed-section technique does not have a sufficient resolving power to evaluate diffusion artefacts over the small distances inside a cell. A technique has been developed which enables the enzyme in small areas inside a cell in a tissue section to be

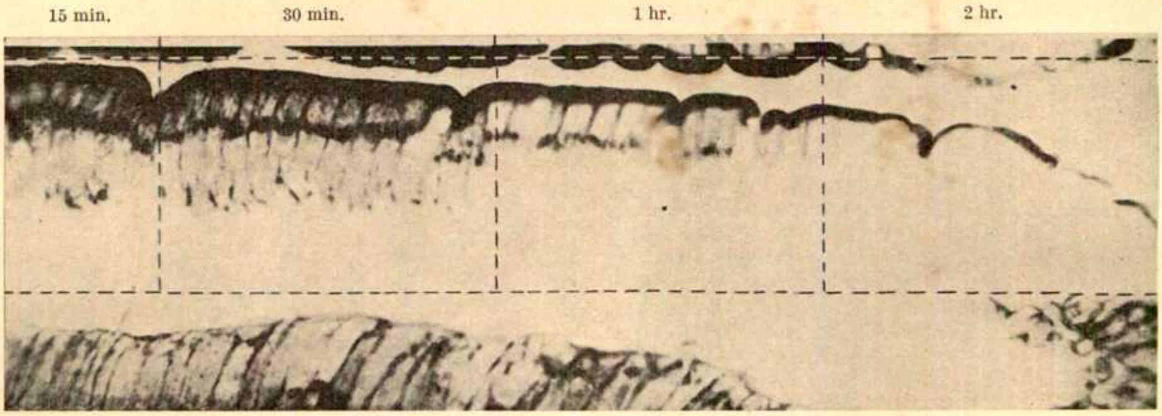

Fig. 1

inactivated. In this way diffusion during a cytochemical reaction can be investigated. The method makes use of the enzyme-inactivating action of the long wave-length ultra-violet light obtained from a glass-jacketed 250-watt B.T.H. mercury lamp. This is focused on the section mounted in water between two coverslips by an 8-mm. apochromatic objective. A mask in front of the lamp acts as the light source, and in this way slits or patterns of small holes can be focused on the section.

In this way areas of a few square microns, for example, a nucleus, can be inactivated. A suitable mask is made of heavy tin foil pricked by a fine glass needle, and mounted on a heat-resisting glass filter. Between the mask and the lamp are several heat filters and a removable intensity filter. Between the mask and the objective acting as a condenser is a cover slip at 45° to the optical axis which reflects in an auxiliary lamp used for taking a photograph of the section and the 'inactivated' spots. Such photographs are taken at intervals during the inactivation to check on movement of the spots. The coverslips holding the section must be firmly mounted and only a small area left unsupported around the section, otherwise the image of the mask may move during the period of irradiation, which for alkaline phosphatase may be 1–2 hr. Several sections besides the inactivated one are mounted on the coverslip and serve as controls. Studies on alkaline phosphatase have been carried out in collaboration with Prof. J. F. Danielli and Dr. J. H. Fodden, and will be published elsewhere. The technique has been to flatten frozen and dried tissue sections on to a coverslip using 95 per cent alcohol. The slip is dried in a desiccator, the wax removed by xylene, the section fixed in absolute alcohol for 15 min. and again dried in a desiccator. The section is then placed directly in water for the inactivating process, thus avoiding concentrations of alcohol likely to dissolve alkaline phosphatase.

The procedures described above should be applicable to many critical enzyme studies at a cytochemical level.

The apparatus is simple to set up, but needs critical adjustment. The coverslips should be the correct thickness for the condensing objective and the mask should be at a distance from the condenser corresponding to the correct tube-length for the lens. The numerical aperture of the illumination beam is kept at, or below, 0·6 to reduce scattered light in the specimen.

Fig. 1 shows a 4-μ section of frozen and dried rat duodenum, with a portion of one villus irradiated with a wide slit as indicated by the dotted line and for the times shown. After irradiation the section was incubated for 5 min. in the Gomori technique for alkaline phosphatase. The details appearing in black in the figure are caused by deposition of calcium phosphate: no counterstain was used.

I acknowledge the helpful interest of Prof. J. F. Danielli in this development.

Crystalline Xylanase

XYLAN is hydrolysed in animals, plants, and by a large number of micro-organisms. Sørensen[1] recently gave evidence that certain bacteria act on xylan to produce xylose-containing oligosaccharides and D-xylose. Whistler *et al.*[2] reported that an enzyme preparation from the medium of *Aspergillus foedidus* hydrolysed corn-cob xylan primarily to xylobiose with no production of D-xylose. An extract of the mould mycelium was separated into two fractions:

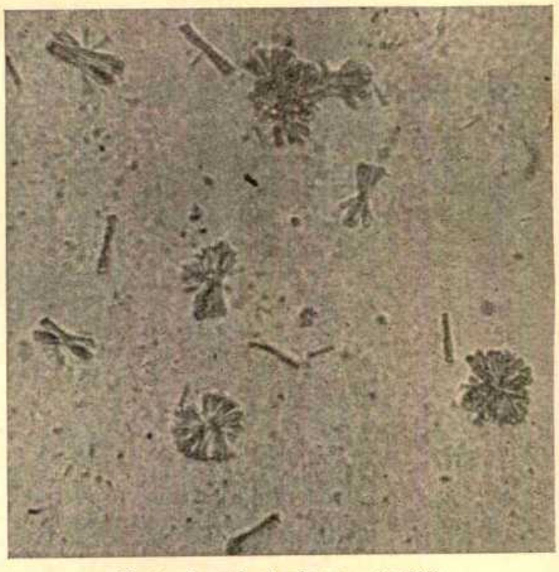

Fig. 1. Crystals of xylanase. (× 600)

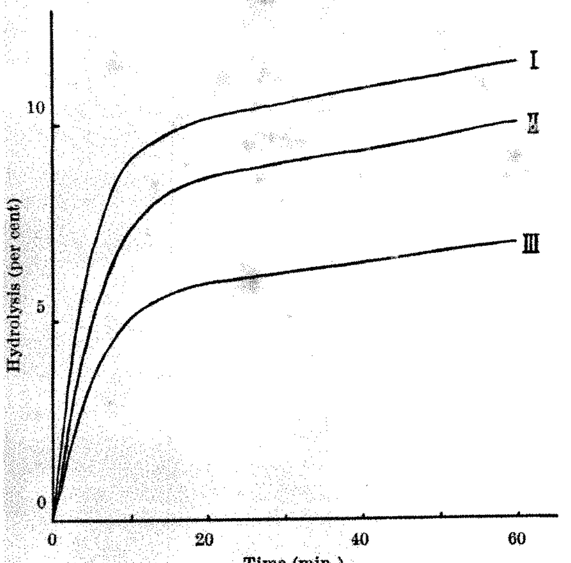

Fig. 2. Hydrolysis of xylan by crystalline xylanase: I, calcium and magnesium ions added; II, calcium ions only added; III, calcium and magnesium ions not added

one which hydrolysed xylan and the oligosaccharides to D-xylose without producing significant amounts of oligosaccharides, and one which hydrolysed xylan to a mixture of D-xylose and oligosaccharides.

From a medium of a *Bacillus* sp. we have crystallized an enzyme which hydrolysed xylan to xylobiose, xylotriose and higher xylose-containing oligosaccharides but produced no noticeable D-xylose.

The bacilli were grown in a medium containing xylan, meat extract, peptone and salts for seven days. 5,000 c.c. of the culture medium was collected and concentrated to 1,000 c.c. and 10 c.c. of 20 per cent basic lead acetate added. After centrifuging, ammonium sulphate was added to the supernatant solution to bring its concentration to 70 per cent saturation. The precipitate was dissolved in 250 c.c. of $M/15$ phosphate buffer (pH 6·0), and dialysed against distilled water. 25 c.c. of 1 per cent rivanol solution was added to the dialysed supernatant solution and the precipitate produced was discarded. The enzyme was precipitated from the supernatant solution by the addition of 500 c.c. of acetone and dried *in vacuo*. 520 mgm. of white powder was obtained. 300 mgm. of this powder was dissolved in 10 c.c. of distilled water and 3 c.c. of acetone was added. After removing the precipitate produced, another 2 c.c. of acetone was added and the solution held at 5° C. Crystals shown in Fig. 1 appeared within one day. The yield was about 30 mgm.

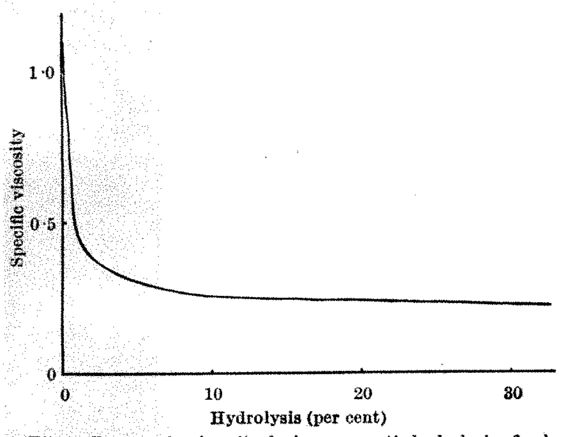

Fig. 3. Decrease in viscosity during enzymatic hydrolysis of xylan

The enzyme was activated by the presence of Ca^{++} and Mg^{++}. If the action of this enzyme on xylan was determined reductometrically and the degree of hydrolysis was plotted against time, the curves in Fig. 2 were obtained. The reaction evidently resolves itself into two phases with widely different velocities: an initial, rapid phase in which about 9 per cent of the xylosidic linkages of the substrate are ruptured and a second, considerably slower, phase showing no definite limit within a reasonable time. The initial phase is accompanied by an extremely rapid decrease in viscosity as shown in Fig. 3.

Paper-chromatographic analysis of the hydrolysates of xylan by this crystalline xylanase showed that xylobiose, xylotriose and higher xylose-containing oligosaccharides were the principal products. Xylose was not produced.

We wish to express our thanks to Prof. K. Yamafuji, of Kyushu University, for guidance.

Radon Content of the Atmosphere

RECENTLY we reported raised levels of atmospheric radon during smoky or fog conditions[1]. It was also pointed out that radon was released into the atmosphere during the normal burning of coal. We have now carried out estimations of the radium contents of a series of representative samples of coals as used in Great Britain. The results of this analysis are shown in Table 1. The methods of estimation were the same as described previously.

Table 1

Source of coal sample	Purpose for which coal is used	Radium content (gm. × 10^{-13}/gm. coal)
South Wales	Power stations	2·56
South Wales	Closed stoves	0·50
Durham	Blast furnace coke	3·16
Durham	Gas-making	2·02
Yorkshire	Domestic	1·65
Yorkshire	Gas-making	3·25
Northumberland	Power stations	2·20
Warwickshire	Domestic	0·70
Nottinghamshire	Domestic	2·10
East Fife	Power stations	0·55

The radium contents of the coals are in a narrow range of values and are similar to those described in the preliminary work. The absence of levels of a higher order suggests that the contribution of radon from this source does not represent a significant addition to the total atmospheric level.

Adsorption of radon on certain fractions of the atmospheric dust nuclei might be suggested as a possible mechanism for its retention in the surface atmosphere. Our experience with samples of atmospheric dust, however, has shown that the associated radioactivity corresponds, in terms of half-life, to the daughter products of radon and not to the active gas itself. The explanation of the raised levels of activity is most likely to be made in terms of the special meteorological conditions associated with fog or smoke-laden atmospheres.

We are indebted to the National Coal Board for the coal samples and to Mr. A. M. Wandless for much useful information on the samples.

Occurrence of Cæsium in Fossils

The possibility of potassium-argon dating of fossils led to the spectrographic examination of a brachiopod (*Lingula*), a lamellibranch (*Gryphaea*) and a trilobite (*Calymene*) for potassium. The alkali metal spectra of *Calymene* showed such marked cæsium enrichment, relative to rubidium and potassium, that a rapid survey was made of the phylum Arthropoda. Two arachnids, four insects, four crustaceans and twenty-eight trilobites were analysed by a semi-quantitative method. To compare different species and genera of trilobites from a single horizon, collections were made from the Upper Silurian Wenlock Limestone at Dudley, Staffordshire. In order to check whether the sediment associated with the trilobites might have an unusual cæsium content many matrices adjacent to the fossils were analysed, collections of sediment also being made for this purpose at Dudley.

From inspection of the potassium and rubidium lines, the K/Rb ratio is not significantly different in the trilobites and enclosing sediments and is about the same as in sediments and igneous rocks. The Rb/Cs ratio was estimated with fair accuracy. This ratio gives a clearer indication of relative cæsium enrichment than the absolute amounts present, for which the reproducibility was poor ($\lambda' = 2$, Ahrens[1]). The Rb/Cs ratio is markedly lower in the trilobites (arithmetical mean = 3·9 ; geometrical mean = 2·4) than in the enclosing sediment (arithmetical mean = 19 ; geometrical mean = 15). Modes determined from histograms are approximately 2·5 for trilobites and 15 for matrix. No significant difference was noted in the ratios of different parts of the same trilobite. Particularly low ratios were recorded for *Deiphon* (Rb/Cs 0·36) and *Paradoxides* (Rb/Cs = 0·26), both spinose forms. The maximum (absolute) amount of cæsium recorded was in *Deiphon*, which contained ~ 250 p.p.m. This striking enrichment is shown in Fig. 1*A*. The matrix associated with *Deiphon* is shown in Fig. 1*B*.

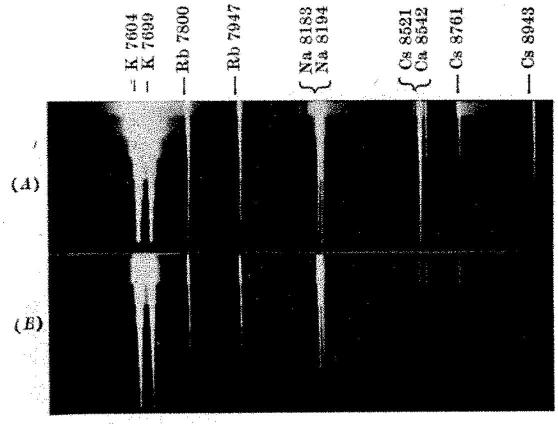

Fig. 1. Alkali metal spectra of (*A*) *Deiphon* ; (*B*) matrix surrounding *Deiphon*

Canney[2] found an Rb/Cs ratio of 15 (arithmetical mean) for 323 sedimentary rocks. Thus the Rb/Cs ratio of the matrix surrounding the trilobites does not differ appreciably from the average for sediments. Cæsium may have been concentrated by the trilobites during growth, or it may have become selectively absorbed after death, in which case the matrix might be expected to be distinctly impoverished in cæsium. The results obtained tend to support the former view, or, if the cæsium enrichment of the trilobites was post-burial, the enclosing sediment was not affected.

While it has frequently been observed that certain metallic elements, for example, copper, are enriched in organisms, it is interesting to note, in the present case, strong enrichment of one alkali element relative to the others with similar chemical properties. The cæsium enrichment is perhaps connected with its large size (Cs^+ : 1·67 A.) and consequent low degree of hydration.

A spectrographic examination was also made of five genera of the phylum Brachiopoda. Of these, *Lingula* (the only chitinous form analysed) showed some cæsium enrichment.

Palæomagnetism of Chemical Sediments

Since previous observations of remanent magnetism of sedimentary rocks have been mainly confined to detrital deposits, we would like to report on new significant results obtained with chemical deposits. In the case of detrital sediments, the question has arisen sporadically as to whether the inclination of the remanent vector is changed by the realignment of the magnetic particles upon meeting the bottom surface in the settling process and also by movements later in the compaction process. This question does not hold in the case of chemical deposits. Perhaps of more importance, these particular rocks exhibit a desirable stability of magnetization.

Some of the rocks sampled consisted of large ellipsoidal, calcareous concretions occurring in the Barnett shale of Mississippian age. These concretions appeared to be syngenetic (or nearly so). Nine locations were sampled at outcrops of the Barnett on the north-west, north, north-east and south-west sides of the Llano uplift in central Texas. The maximum distance between locations is 73 miles.

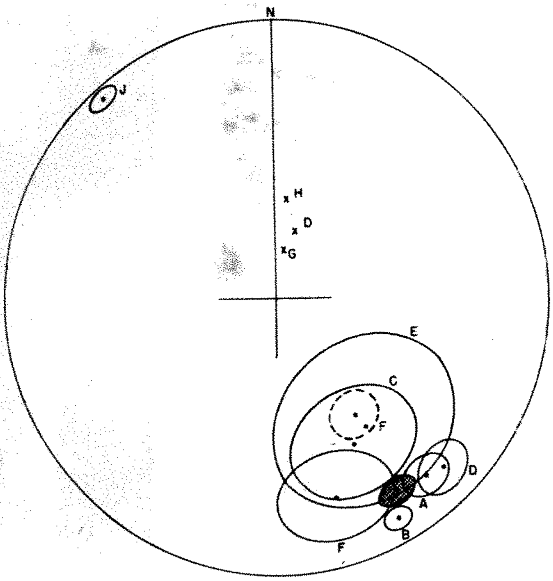

Fig. 1

Fig. 1 shows a lower hemisphere plot on a Schmidt projection of the magnetic polarization directions for the various locations labelled with capital letters; the Fisher circles of confidence at the 5 per cent significance-level are indicated with the corresponding letters. At locations *A*, *D* and *F* two concretions each were sampled; at *B*, three concretions and a limestone bed; at *C*, two limestone beds; at *E*, one concretion; and at *J*, one limestone bed. The crosses indicate averages as follows: one measurement from a weathered shale at *D*; two measurements from a concretion (not typical) at *G*; and three measurements from a limestone bed at *H*. These points are not considered in the analysis since they obviously indicate instability of magnetization of the rocks. The dashed circle is obtained from twenty-two measurements from ten shale samples at *F*. These data are also not considered since the magnetizations were weak and the vectors scattered; also, the shale is of detrital origin. The cross-hatched circle of confidence is found from a total of more than sixty measurements for all the samples indicated by solid circles in the south-east quadrant. Thus, from this average direction of magnetization and the usual dipole relationship, the position of the south (not seeking) magnetic pole is found to be at 39° N. latitude and 124° E. longitude. From eight measurements of the reversely magnetized limestone at *J*, the north pole is located at 42° N. latitude and 142° E. longitude. These positions are in good agreement with Carboniferous pole locations by others: Belshe[1], 36° N. latitude and 137° E. longitude, found from Carboniferous sediments in England; and Runcorn[1], 49° N. latitude and 120° E. longitude, found from Pennsylvanian sediments in Arizona.

As to the stability of magnetization of the Barnett in geological time, we present the following favourable evidence: (1) The direction of magnetization is drastically different from that of the present Earth's field. (2) With a few exceptions, the data from widely separated locations in the uplift area agree. (3) The pole positions agree with those found by others from more widely separated locations. (4) When sense is disregarded, the direction of reverse magnetization at *J* agrees with the direction obtained from the other samples (we are not committed to a 'normal' direction). (5) There is an indication of stability, though not conclusive, obtained from two samples of sharply tilted strata[2] near faulting thought to have occurred in Pennsylvanian time. (6) With a few exceptions, there is good agreement between the results obtained from a variety of lithology: limestones, shales, limy shales and concretions. Regarding point (4) above, a study of thin sections of the Barnett samples, including those reversely magnetized, indicates that the most likely ferromagnetic mineral present is hæmatite, which is formed as a result of oxidation of syngenetic pyrites. No differences were noted which might give credence to a magnetization of the rock in the reverse direction to the Earth's field in one case and not in the other.

Both the field evidence and the petrographical observations support the conclusion that the calcareous concretions are syngenetic. They are certainly formed as a result of chemical processes and they contain very little detrital matter. Therefore the amount of detrital ferromagnetic minerals that could be present must be very small indeed and could scarcely account for the magnetic intensities observed. This seems to be excellent evidence that the ferromagnetic minerals are formed through chemical processes and probably acquire their remanent magnetism during these processes. This we feel to be a significant conclusion.

Other Carboniferous rocks have been sampled, and we hope to give a more detailed report in a later publication.

Angle of Spread of Free Jets

THE value of the angle of spread of free turbulent jets has been of great interest to theoretical workers, and its practical application has become important to engineers in the field of combustion engineering. When such a jet of fluid is injected into quiescent surroundings the original kinetic energy of the jet is gradually dispersed in the turbulent mixing region of the jet. The pressure in the jet is very nearly the same as in the surroundings; but a surface of discontinuity separates the stream and the neighbouring fluid. The boundary is well defined apart from slight local instability. Surrounding fluid is entrained at the boundary so that the velocity of the jet decreases while the mass of fluid increases, the momentum remaining constant. In this way the jet spreads in the form of a cone having a well-defined angle. Measured values of the jet half-angle have been variously reported from 7° to 20°. Using Prandtl's hypothesis, Tollmien calculated the jet half-angle to be 12°. Recently, a new measurement of this angle was made at Sheffield, and the influence of jet fluid density investigated.

During the development of a technique for introducing a buoyancy effect into furnace models, as previously reported[2], a jet of magnetite slurry was injected into a large, slowly moving mass of water in a 'Perspex' box. The slurry, being intensely black,

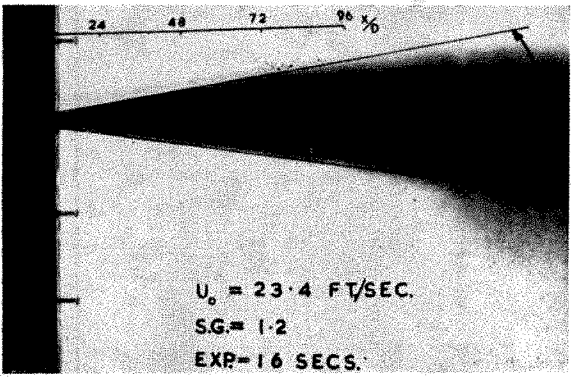

Fig. 1. Angle of spread of free jet; density ratio 1·2

provided excellent photographs of turbulent jets, such as the one shown in Fig. 1, from which the jet half-angle was deduced to be 8·5°. This agrees with the value reported by Binnie[3] for a water jet, but is less than the results quoted for gaseous systems. This result was constant for several values of the nozzle velocity and the exposure time of the photographs. Although the jet was fired horizontally, the density difference between nozzle fluid and surrounding fluid did not affect the early trajectory, where the angle was measured, as the half-angles measured above and below the horizontal were found to be equal.

In the theoretical analysis of the path taken by jets of initial density different from their surroundings, it is important to know if the jet angle, and hence the spread functions of velocity and concentration, vary with the density ratio. Measurements of the jet angle were made with nozzle fluid of specific gravity ranging from 1·0 to 2·0, and no variation in the jet angle was found (Fig. 2). This contradicts the results of Keagy and Weller[4], who measured the jet angle for vertical streams of carbon dioxide, nitrogen and helium expanding in air and found a considerable variation.

By writing down the conservation laws, it is possible to derive the following approximate expressions for axial values of velocity and concentration in a free jet at large values of x.

$$U_m = K_1 U_0 \frac{D}{x} \sqrt{\frac{\rho_0}{\rho_s}}$$

$$C_m = K_2 C_0 \frac{D}{x} \sqrt{\frac{\rho_s}{\rho_0}}$$

where U_m, C_m are, respectively, axial values of velocity and concentration of tracer inserted in the nozzle fluid; U_0, C_0 are the initial values of velocity and nozzle fluid tracer concentration respectively; K_1, K_2 are derived from the particular radial functions of velocity and concentration used, respectively; D is the nozzle diameter; x is the distance along the axis in the direction of projection; ρ_0, ρ_s are the densities of nozzle fluid and surrounding fluid, respectively.

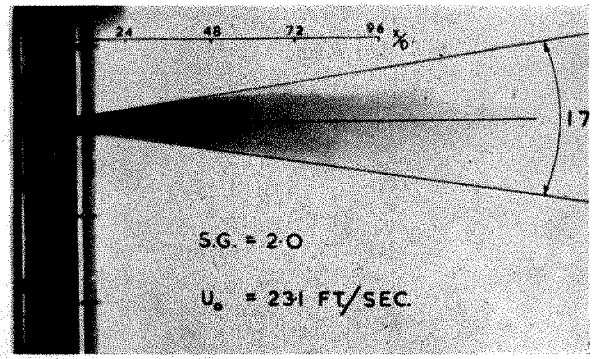

Fig. 2. Free jet; density ratio 2·0

If the angle of spread is affected by density differences then K_1, K_2 will be a function of ρ_0/ρ_s. On the other hand, if the jet angle is unaffected by density, as suggested by the magnetite slurry experiments, then K_1, K_2 will be constant and identical to the values determined for constant density systems.

Comparative Rates of the Slow Combustion of Coke in Oxygen and Nitrogen Dioxide

MAINLY to assist in understanding the reactions of carbons with oxygen, there have been a number of studies of the kinetics of the reactions of solid fuels with nitrous oxide[1-3]; but we are unaware of any comparable work with nitrogen dioxide. This compound, which has been shown to influence the decomposition and smoke-producing tendencies of coals[4,5], is of special interest as an oxidant in view of the comparatively easy thermal dissociation probably producing oxygen atoms in the primary stage:

$$NO_2 \rightarrow NO + O$$

It is also well known as a sensitizer of several gas-phase combustion reactions[6], and it is conceivable that, when introduced into the carbon/oxygen system, it could act as a catalyst and/or react separately with carbon.

Preliminary studies in these laboratories have shown that the additions of up to 1 per cent by volume of nitrogen dioxide to an air stream fed to a column composed of a high-temperature metallurgical coke maintained at 480 ± 2° C. produced a marked increase in the rate of gasification of the sample (Fig. 1). At 1 per cent nitrogen dioxide addition, the rate is about 56 per cent greater than in air only, although the 'available' oxygen in this amount of nitrogen dioxide is only 0·024 of that contained in the air stream. Further experiments indicated that the

Table 1. RELATIVE RATES OF REACTION OF COKE WITH SEVERAL GAS MIXTURES (480° ± 2° C.)

Reaction of coke with	Relative rate
Air	1·00
Air + 1 per cent NO_2	1·58
99 per cent N_2 + 1 per cent NO_2	0·57

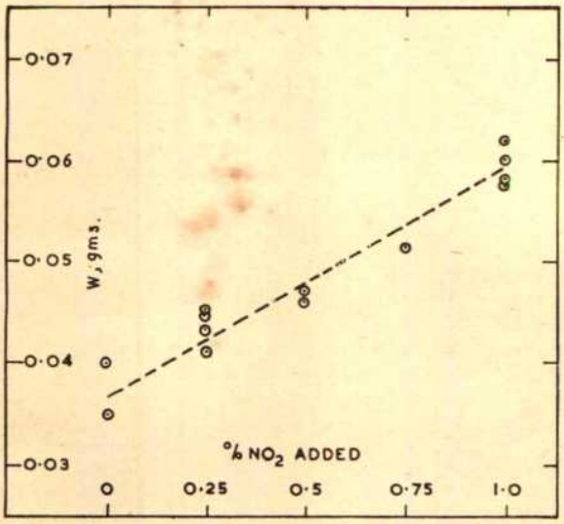

Fig. 1. Influence of NO_2 additions on the weight loss (*W*) of coke samples exposed to an air stream for 30 min. Initial weight of coke, 2·45 gm.; air velocity, 600 c.c./min.; coke size, 10–14 B.S.S.; coke temperature, 480 ± 2° C.

increased rates of reaction shown in Fig. 1 are due to a separate reaction between nitrogen dioxide and the coke, that is, the addition of nitrogen dioxide does not appear to influence the rate of the carbon/oxygen reaction; this was shown by a comparison of the reactivity of the three mixtures, air, air + nitrogen dioxide and nitrogen + nitrogen dioxide, towards the coke, the relative rates of reaction in each case being given in Table 1.

Consideration of the rate measurements of Bodenstein and Ramstetter[7] for the homogeneous thermal decomposition of nitrogen dioxide in the temperature-range 320–380° C. leads to the conclusion that in the present experiments at 480° C. with a catalytic surface (coke) present, freshly formed oxygen is the effective gasifying agent. Since this oxygen reacts so rapidly compared with the normal gas, it is probable that it is in the atomic form.

Instability of Uniform Concentration Conditions in Suspensions under Shear

In an earlier paper by one of us[1] it was shown theoretically that in a suspension under shear the action associated with an isolated suspended particle will be a minimum when the particle follows the streamline characterized by minimum velocity gradient. The principle of least action requires that a particle initially situated at a point in a velocity field at which the gradient is not a minimum should move with a component of motion normal to the direction of flow towards regions of lower velocity gradient. In a subsequent paper[2] direct evidence of this component was adduced from a study of the motion of streams of suspended particles.

The existence of this component points to the conclusion that, during the shearing of a suspension, the motions of the suspended particles lead to a progressive increase in their concentration in those regions where the rate of shear is least and a diminution of concentration where the highest rates of shear prevail. Preliminary experiments designed to investigate variations of concentration during shear have now been carried out, and evidence of the effect predicted is given below.

The apparatus used in these experiments consisted of a co-axial glass cylinder arrangement in which the inner cylinder was fixed and the outer was rotated by means of a variable-speed motor. The inner cylinder, which was a glass rod of 0·6 cm. diameter, was arranged with its lower end beneath the surface of a shallow pool of mercury contained in the outer cylinder. The latter cylinder was a glass tube of internal diameter 4·9 cm., and throughout the experiments its rate of rotation was 2·1 rev./sec. The values of these quantities are, however, in no case critical.

The suspension employed consisted of sieved polystyrene beads of mean diameter 181μ and of range ± 30μ, suspended in an aqueous sucrose solution of the same density. The concentration of the suspension was 0·025 gm./cm.³ and that of the solution 0·155 gm./cm.³ of distilled water. The depth of the suspension used was 21·0 cm. and its temperature during the experiment was 13° C.

Fig. 1 shows the appearance of the suspension two and a half hours after switching on the apparatus. It is clear from this that the effect of shearing the suspension is to develop concentration gradients across the annular space such that the concentration falls to a very low value near the outer wall of the apparatus. This condition remains stable indefinitely.

The concentration variations which gradually develop during the shearing of a suspension in a non-uniform velocity field, it is suggested, are fundamental to the phenomena associated with anomalous viscosity. It would appear that the condition of uniform

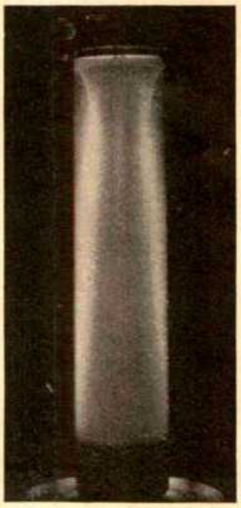

Fig. 1. Concentration variations in a suspension under shear

concentration of such disperse systems under shear is unstable.

Electron Bombardment of Counting Diamonds

The response of six diamonds as conduction counters for α- or β-radiation was determined, using as a criterion the maximum pulse-height versus applied-field curve obtained under conditions of minimum polarization. Without removal from their holders, the diamonds were then exposed to electron bombardment from the 15 MeV. linear accelerator at St. Bartholomew's Hospital Medical College, the counting response being redetermined after each successive bombardment. The electron beam from the accelerator passed through a water collimator. The diamond holders were cooled by water, and the overall temperature of the diamonds was kept below 70° C. during the bombardment. Radioactivity induced in thin strips of copper was used for the routine electron flux dosimetry, the absolute flux estimates being obtained by comparison with calorimetry measurements.

In each of the six counting diamonds bombarded the counting pulse heights progressively decreased with increasing bombardment flux. After a total flux of about 4×10^{16} electrons per cm.^{2} delivered at a rate of 3×10^{13} electrons per cm.^{2} per sec., the counting response was barely detectable, and the diamonds were perceptibly bluish-green in colour. In some specimens the insulation resistance also decreased after bombardment. Two non-counting diamonds were also bombarded and became bluish-green after about the same total electron flux.

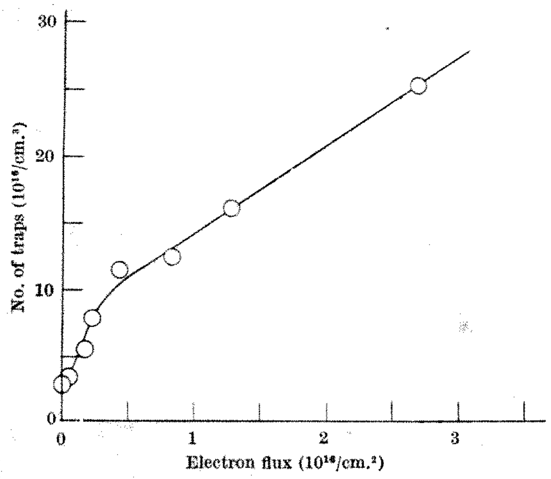

Fig. 1. Formation of additional traps in diamond by electron bombardment

The reduction in counting response is attributed to the trapping effects of additional vacant sites and interstitial carbon atoms introduced into the lattice by electron bombardment. Making certain assumptions, estimates of the number of traps introduced can be obtained from the counting response curves. Fig. 1 shows the typical increase in trap concentration with total bombardment flux. In each instance it was found that the initial rate of trap production was significantly higher than the subsequent rate. There is at present no direct experimental evidence of the causes of this effect; but some form of radiation annealing and the formation of clusters of defects, perhaps preferentially in the vicinity of barrier layers, may be suggested as possible factors. A small amount of thermal annealing at room temperature could also be detected after the lower total bombardment fluxes.

The effect on the counting response of high-energy electron bombardment is generally similar to that of neutron bombardment as reported by Benny and Champion[1]. However, the primary damage produced by electrons should be single or small groups of vacancies and interstitial atoms, whereas neutron bombardment can also give rise to larger disordered regions.

A fuller account of these experiments will be given elsewhere.

We are indebted to Dr. F. C. Champion for helpful advice and to Prof. J. Rotblat for facilities provided at St. Bartholomew's Hospital Medical College.

A New Complex Phase in a High-Temperature Alloy

The grain boundary phase (Fig. 1) in Allegheny–Ludlum Steel Corporation's A-286 alloy has been separated electrolytically and examined by X-ray diffraction. (The nominal composition of this alloy is 0·05 per cent carbon, 15 per cent chromium, 26 per

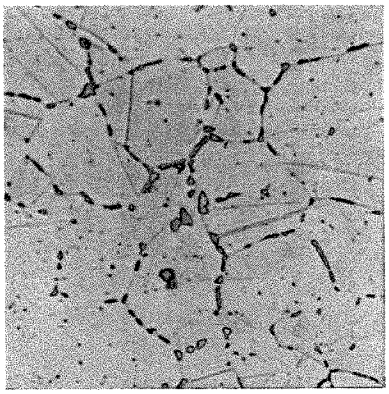

Fig. 1. Etchant: 92 per cent hydrochloric acid, 5 per cent sulphuric acid—3 per cent nitric acid. (× 500)

cent nickel, 1·15 per cent molybdenum, 0·50 per cent silicon, 53·5 per cent iron, 2·0 per cent titanium, 0·17 per cent aluminium, and 0·2 per cent vanadium.) This new constituent has been arbitrarily designated *G* phase.

Residues from several alloys having various heat treatments below the solution temperature (1,000° C.) contained *G* phase, which gave identical inter-planar spacings and intensities.

Semi-quantitative chemical analyses indicate the predominant element to be nickel with appreciable amounts of titanium and silicon and some of iron. This phase is more acid-resistant than TiC, presumably owing to the silicon content.

Microscopic studies show a direct relation between the silicon content of the alloy and the abundance of *G* phase, which together with the chemical results indicate that silicon plays a fundamental part in its existence.

Table 1. DIFFRACTOMETER DATA ON *G*-PHASE POWDER USING COPPER $K\alpha$ RADIATION

107	1·082	22	—
108	1·077	23	—

The accompanying table lists the interplanar spacings measured from a diffractometer recording and integrated intensities above background (240 c.p.s.) determined by the time to register 2^{16} counts. The $(h^2+k^2+l^2)$ values are those of a face-centred cubic lattice with parameter $a_0 = 11·20$ A. The photographic powder patterns with copper $K\alpha$ radiation are unusually clear and contain as many as fifty-five lines, all of which can be indexed on the face-centred cubic lattice. There are evidently no systematic absences other than those imposed by face-centred symmetry; hence, the possible space groups are F_{23}, Fm_3, F_{432}, $F_{\bar{4}3}m$, and Fm_3m. This space group limitation rules out the η-carbide structure (Fd_3m), but not that of the $M_{23}C_6$ carbide (Fm_3m); however, the lattice parameters and X-ray intensities of the latter, which are also listed in the table, do not compare favourably with those of *G* phase. This phase, then, appears to have a new structure.

Primary Action of X-rays on Lysozyme

THERE is a number of unsolved problems concerning the effect of irradiations on smaller structures of living systems, such as proteins and protein complexes. Many researches have recently been carried out by irradiating enzymatic and non-enzymatic proteins; but most of the results obtained are not quite clear and are of only relative interest, especially if we consider the following points: (1) the effect of irradiations has been studied on diluted and concentrated protein solutions; (2) when proteins have been irradiated in the dried state, the preparations employed contained some impurities which have a protective action.

Rajewsky[1-3] has worked on these problems for some years; and, at present, we are carrying out in his Institute some investigations with the aim of finding out how X-rays act primarily on protein and amino-acid molecules.

The results given in this preliminary communication are concerned only in what follows on the direct action of X-rays on lysozyme. The reason why we have chosen lysozyme is that this protein is very easily purified and crystallized, it is one of the smaller protein molecules and it possesses well-known biological activity. To prevent complications by the action of free radicals of the solvent, all irradiations have been carried out on dry material.

Lysozyme, crystallized according to Alderton and Fevold[4], has been irradiated with soft X-rays in 'Dermopan' apparatus (beryllium window; 45 kV.; 25 m.amp.; at distance of 2 mm. from the window, 1 million r. per minute) and different times of exposure were made to give doses between 2 million r. and 5 million r.

After irradiation the protein was hydrolysed with 5 *N* hydrochloric acid at 100° C. for 18 hr.; the hydrochloric acid was removed in vacuum and the composition was examined with the aid of high-voltage paper electrophoresis. The technique was essentially that of Wieland[5].

A typical pherogram obtained from control (not irradiated) and irradiated lysozyme is shown in Fig. 1.

Here there is good evidence of the modifications induced on lysozyme after irradiation: it is clear that significant changes occur in composition of the acid fraction of irradiated lysozyme; but the most interesting result is the occurrence of several fractions on the basic side of the pherogram, which are moving faster than the fastest basic amino-acid (lysine). In Fig. 1 it is also possible to observe a decrease of lysine in the irradiated lysozyme.

To learn something about the neutral amino-acids of the irradiated lysozyme, in some experiments, after

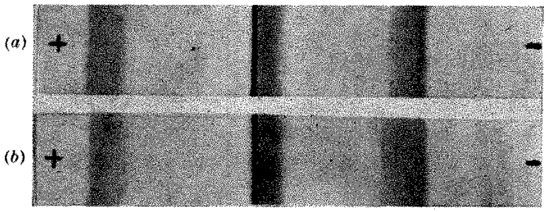

Fig. 1. Electrophoretic behaviour of control (*a*) and 5 × 10^6 r. irradiated (*b*) lysozyme hydrolysate. Equal amounts of nitrogen content for both samples. *p*H 6·0 buffer; pyridine 10 per cent, glacial acetic acid 1 per cent in water. 1,500 V.; potential gradient 40 V./cm. Running time 60 min. The fractions have been revealed with ninhydrin

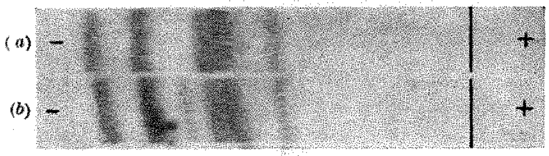

Fig. 2. Electrophoretic separation of neutral amino-acids from control (*a*) and 5×10^6 r. irradiated (*b*) lysozyme hydrolysate. Equal amounts of nitrogen content for both samples. 1,500–2,000 V.; potential gradient 40–55 V./cm. Running time 80–60 min. The fractions have been revealed with ninhydrin. *p*H 1·9 buffer; glacial acetic acid 15 per cent, formic acid 5 per cent in water

separation of the basic and the acid fractions, we eluted the neutral fraction from the paper. The amino-acids of this fraction have been separated again by high-voltage paper electrophoresis; Fig. 2 shows the results obtained in one of these pherograms.

It is of interest to note the occurrence of at least one single new compound between the neutral amino-acids of irradiated lysozyme.

From the results reported above it is evident that after irradiation of a protein like lysozyme the amino-acids are changed in some very complex way, for example, α-ketoacids and lactones of α-amino-acids have also been found in the hydrolysate of irradiated lysozyme.

Detailed results on the chemical composition of irradiated lysozyme, its physicochemical properties and its enzymatic activity will be published elsewhere.

Prevention of Psychological Effects of *d*-Lysergic Acid Diethylamide (LSD 25) by its 2-Brom Derivative (BOL 148)

IN view of the blocking effect often exerted by the close chemical analogue of a pharmacologically specific agent, we tried to determine whether the psychological symptoms induced by D-lysergic acid diethylamide (LSD 25) could be influenced by one of its psychologically inactive derivatives. The 2-brom derivative of LSD 25 (BOL 148) exerts no psychological effects[1].

Six volunteers who showed definite mental symptoms when given 50 or 75 μgm. LSD 25 in the preceding control experiment were pretreated with 2–3 mgm. BOL 148 by mouth daily for one or two days. On the day of the experiment they received one further mgm. BOL 148 1–3 hr. before LSD 25 (50–75 μgm.) was administered. Psychological symptoms were completely absent in those three cases who received two days pretreatment with BOL 148, and reduced to abortive and short-lasting changes in the other three cases who were treated only on the day preceding the experiment. The latter showed some subjective difficulty in concentration only, which could not be established objectively. In all cases, euphoria, depersonalization and all marked sensory symptoms observed in the control experiment did not appear.

In contrast, 0·5 mgm. or 1·0 mgm. BOL 148 injected intravenously in another four volunteers at the height of LSD 25 symptoms did not produce any noticeable or persistent changes in the symptoms of the LSD intoxication.

The fact that a substance closely related to LSD 25 can block the mental disturbances induced by it may throw some light on the mode of action of the drug.

We are indebted to Dr. H. Holgate, of Messrs. Sandoz Products, Ltd., for a generous supply of drugs LSD 25 and BOL 148.

A Method for following Lipolysis induced by Heparin

THE heparin clearing effect on postprandial lipæmic turbidity of blood serum has been demonstrated by Hahn[1]. Recently, it has been shown that heparin clearing is accompanied by the formation of a new electrophoretic component[2] and by an increase in free fatty acid[3]. That this process is of an enzymatic nature is now beyond doubt[4]. Since higher fatty acids are known to cause a depression of the second part of the polarographic protein double wave of albumin[5,6], the effect of heparin clearing on the polarographic behaviour of human blood serum was investigated because it has been shown that the polarographic effect of higher fatty acids on human blood serum can be accounted for only by the interaction of serum albumin with the fatty acids[6]. It was found that the intravenous administration of 0·5 ml. of 5 per cent heparin to six postprandial lipæmic humans as well as to six fasting subjects causes a marked depression of the second part of the polarographic protein double wave. Tables 1, 2 and 3 give the heights of the second wave in one individual which is representative of the entire group. In all cases the results were qualitatively identical.

Table 1

	Height of second wave in mm. (from cobalt wave)
Fasting	48
3 hr. after fatty meal	50
5 min. after 0·5 ml. of heparin *in vitro*	29
Fasting	58
5 min. after 0·5 ml. of heparin *in vitro*	44

Heparin added *in vitro* to blood serum does not show such an effect. The onset of the heparin effect is extremely rapid and its polarographic result can still be demonstrated in blood samples drawn 15 min. after heparin injection (Table 2).

Table 2

	Height of second wave in mm. (from cobalt wave)
Fasting	54
3 hr. after fatty meal	55
5 min. after 0·5 ml. of heparin *in vitro*	44
10 min. after 0·5 ml. of heparin *in vitro*	41
15 min. after 0·5 ml. of heparin *in vitro*	41

The technique of this procedure is extremely simple, consisting in taking a polarographic recording of a blood serum dilution 1 : 400 in Brdička's cobaltic solution (0·001 *M* $[Co(NH_3)_6]Cl_3$, 0·1 *M* NH_4Cl, 0·1 *M* NH_3). The effect of intravenous protamine

Table 3

	Height of second wave in mm. (from cobalt wave)
Fasting	60
3 hr. after fatty meal	66
5 min. after 0·5 ml. of heparin *in vitro*	42
5 min. after 5 ml. of 1 per cent protamine *in vitro* (that is, 10 min. after heparin)	55
Fasting	54
5 min. after 5 ml. of protamine	56

following heparin administration is also quite striking (Table 3).

Protamine given by itself does not show any effect. The *in vitro* effect of heparinized individuals on lactescent blood serum can also be demonstrated by this method. Since the existing methods of studying heparin-induced lipolysis are rather tedious and cumbersome, the method reported here may prove of some value. A considerable advantage for the physiological application of this method is the minute amount of blood serum required for polarographic measurements.

The mechanism of the phenomena described and the results of their application in the study of the physiology and pathophysiology of lipid transport will be reported in detail elsewhere.

Osmotic Pressure in the Intestine of the Cow

Many investigations of the osmotic pressure in the intestine have been carried out. In those performed on laboratory animals it always turned out that, in the small as well as in the large intestine, there is isotony with the blood.

In our investigation the osmotic pressures of the press-juice of the faeces and of the intestinal content of the cow have been determined. The faecal juice was obtained by pressing the faeces in a membrane press. The freezing-point depression method was used for measuring the osmotic pressure.

With fifty cows the mean value of the freezing-point depression in the press-juice of the faeces appeared to be 0·350 deg. C., the extremes being 0·240 and 0·430 deg. C. The freezing-point depression of the cow's blood is 0·560–0·590 deg. C. The press-juice of the cow's fæces is therefore rather strongly hypotonic with regard to the blood. From the data in the literature, however, isotony with regard to the blood had been expected.

Table 1

	Freezing point depression (°C.)
Experiment 5	
b, rennet-stomach (abomasum)	0·549
a, duodenum	0·684
c, middle small intestine	0·714
j, caecum	0·620
h, beginning of large intestine	0·530
f, middle of large intestine 1	0·489
g, middle of large intestine 2	0·449
d, end of large intestine	0·398
Experiment 6	
f, rennet-stomach (abomasum)	0·490
a, duodenum	0·588
b, middle of small intestine 1	0·951
c, middle of small intestine 2	0·822
d, end of small intestine	0·628
n, caecum	0·606
m, beginning of large intestine	0·549
l, middle of large intestine 1	0·388
k, middle of large intestine 2	0·364
j, middle of large intestine 3	0·339
g, end of large intestine	0·375

Afterwards, with six cows, the osmotic pressure in different parts of the intestine was determined. In Table 1 the results of two of these determinations are given.

The content of the abomasum is slightly hypotonic with regard to the blood. In the small intestine, however, mostly rather strong hypertony occurs; but in the end of the small intestine and in the caecum isotony with regard to the blood is practically re-established. In the large intestine the contents gradually become hypotonic. It is clear that this last-mentioned fact may be of great importance for the mineral balances and the mineral metabolism of the cow.

We conclude, therefore, that the generally accepted tendency of the intestinal content towards isotony with the blood does not hold for the cow.

Deficient Water-binding in Pathological Horny Layers

The pathogenesis of most scaling skin conditions is obscure. Although it has been often assumed that abnormal processes of keratinization play a major part, recent work has emphasized the importance of the water-soluble components of the horny layer. These components contribute to the water-binding ability and pliability of the normal skin surface[1]; their amounts are reduced in psoriatic scales[2] and skin[3].

We have determined the water-uptaking capacity at 100 per cent relative humidity and the amino-nitrogen content of normal horny layer (callus) and of scales from six patients with psoriasis and two patients with ichthyosiform erythroderma, a congenital scaling skin disease. Determinations were made in pulverized, ether-defatted, non-hydrolysed horny material, in the aqueous extracts and the water-insoluble residue. Callus took up about 50 per cent more water than the pathological specimens (28 per cent versus 19 per cent). After extraction with water, the water-binding ability of all the residues became practically the same (17–19 per cent).

The assumption that the water-soluble components were responsible for the decreased water-binding ability of the pathological specimens was further supported by precipitating these substances from the extracts with an excess of acetone and determining their water-binding capacity. The acetone-precipitable material from the pathological scales took up considerably less water than their normal counterparts (47–49 per cent versus 114–116 per cent).

The most important dialysable water-binding components of the horny layer are free amino-acids[4,5]. The diminution of the free amino-nitrogen in pathological scales is confined to the water-soluble portion

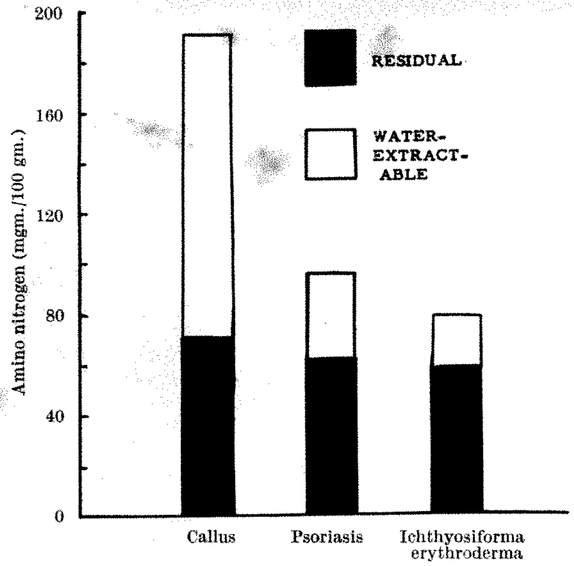

Fig. 1. Free amino-nitrogen in non-hydrolysed calluses (3 specimens), psoriatic scales (6 patients) and scales from a congenital scaling disease (2 patients)

of the scales. The amino-nitrogen content of the residue, obtained by calculation and, in most cases, by actual estimation, was virtually the same in normal and pathological specimens (Fig. 1).

These findings suggest that in these scaling conditions the main fault may not lie in the keratinous portion of the horny layer or in the process of keratinization. The decrease in the free amino-acids may result from an abnormal protein metabolism in the differentiating epidermal cells. The previously reported high —SH content of psoriatic scales[6,7] may also be an expression of such an abnormal metabolism in the non-keratinizing portion of the cells, because these groups can be extracted with water or detergents.

Removal of the major hydrophilic component of the horny layer by a combination of lipid solvents and water results in decreased water-binding capacity and brittleness[1]. When, in certain pathological conditions, these substances are diminished, the horny layer may have a different appearance. Although the reported changes are not in themselves specific for any scaling disease, their combination could be distinctive for certain conditions, for example, in psoriasis with the simultaneous occurrence of high —SH values and low water-extractable amino-nitrogen. Further identifying features may be revealed by studying the amino-acid composition of the water-soluble portion of various pathological cornified epithelia. Studies of this nature are in progress. This study was supported by U.S.P.H.S. Grant *G*-4257 *C*.

Mitosis in Migrating Epithelial Cells

IT is generally believed that the absence of mitotic activity in migrating epithelial cells is one of the characteristic features of repair in epithelia. Migration alone is held to be responsible for epithelialization in the early stages of healing. Increased mitotic activity occurs later at some distance from the wound margins, and spreading cells are considered to exhibit mitosis only after they have become firmly fixed to the underlying tissues.

Recent studies in the cat have shown that certain epithelial cells do undergo mitotic division when migrating. Observations on regenerating transitional epithelium in the urinary bladder[1] revealed that, within two days of creating an excision ulcer in the mucosa, increased mitotic activity was present not only in the epithelium of the undisturbed mucosa surrounding the lesion but also in the cells that were spreading in a single or double layer over the floor of the ulcer. When a similar lesion was made in the gall bladder[2], a very striking increase in proliferative activity was noted in the columnar epithelium within twenty-four hours of operation. Again, nuclei in all phases of the mitotic cycle were found in the spreading cells, as well as in the epithelium at and near the ulcer margins.

Migration of the stratified epithelial cells in the urinary bladder may be responsible for the epithelialization of the defect, and mitosis may be concerned only with increasing the number of layers of cells. However, in the simple epithelium of the gall bladder, it is difficult to maintain that mitosis in spreading cells is not playing some part in covering the lesion. Both types of epithelia display a very early onset of increased proliferative activity, which would appear to be well established before the cells can be said to be firmly attached to the underlying tissues. In a study of the regeneration of tracheal epithelium in the rat, Wilhelm[3] also found some evidence of mitosis in migrating cells.

These findings are clearly at variance with current concepts of epithelial activity during wound healing. It is to be noted that the majority of investigations on wound healing have been carried out on skin and cornea, and generalizations derived from these two tissues may be misleading when applied to others that have received less attention.

The Juvenile Hormone of Insects

SINCE the pioneering researches of Wigglesworth[1] the corpora allata have been known as the source of a 'juvenile hormone' which opposes or prevents the metamorphosis of immature insects. The presence of this hormone exerts a biochemical restraint on the cellular transformations responsible for the metamorphosis of the insect as a whole. These facts have been ascertained by biological procedures such as parabiosis and the transplantation of living corpora allata[2]. The hormone itself has apparently not been extracted or obtained apart from the living insect or endocrine organ.

Studies of the Cecropia silkworm (*Platysamia cecropia* L.) have recently revealed a rich depot of the corpus allatum hormone in the abdomen of the adult male of this moth. By the extraction of abdomens with organic solvents it has been possible to prepare the first potent extracts of the juvenile hormone. The latter, when injected into previously chilled pupæ of *Platysamia cecropia* or *Telea polyphemus*, duplicate the results obtained by the implantation of living, active corpora allata; that is, the formation of the adult moth is blocked and the pupa is forced to transform into a second pupa. The hormonal extracts from Cecropia have also been found active when tested on *Pieris brassicae* (Lepidoptera), *Tenebrio molitor* (Coleoptera), *Rhodnius prolixus* (Hemiptera) and *Periplaneta americana* (Blattaria).

The hormone is readily extracted when one or more adult male abdomens are blended at room temperature with ether, petroleum ether, ethanol or methanol. Ether appears to be the solvent of choice. After evaporation of the solvent in a water bath, the hormone is recovered as a residual, golden-yellow, non-toxic oil of low viscosity. Each abdomen yields approximately 0·2 ml. of the active oil, and it is therefore possible to obtain a manageable volume of extract from even a single abdomen. When injected into Polyphemus pupæ weighing 5 gm., 0·025 ml. of the oil gives a clear-cut effect.

The hormone is insoluble in distilled water, and at all stages in extraction can be washed repeatedly with water without loss of activity. The hormone resists extraction when fresh abdomens are blended at room temperature with acetone, chloroform, benzene or carbon tetrachloride; but after initial extraction with ether, the hormone is soluble in acetone.

In addition to the above-mentioned solubilities, preliminary studies show that the hormone is a heat-stable substance which, at room temperature, is resistant to aqueous alkali (5 N), acid (0·2 N), and anionic and cationic exchange resins.

Only a trace of hormone is extractable from the heads and thoraces of male Cecropia moths, even though the corpora allata are located in the head. Evidently, little hormone is present at any one time in the corpora allata or the blood. But the hormone is easily eluted from any of a number of tissues in the abdomen of the male moth. The abdomen and its contents apparently act to extract the hormone continuously when the latter is secreted in the adult moth and during the final week of adult development. If one excises the corpora allata before this period, then no hormone is recovered later on from the abdomen. For reasons which are not understood, it has been impossible to extract any hormone from the abdomens of female Cecropia moths or from any part of male or female Polyphemus moths.

Endocrine studies making use of the extract have already revealed that the hormone is inactive when injected into isolated pupal abdomens or into other preparations where the prothoracic gland hormone is absent. The juvenile hormone intervenes in reactions to the prothoracic gland hormone which occur early in adult development, that is, during the first few days of the twenty-one days required for adult development at 25° C. It has no effect when injected after the fourth day. In the experiments performed thus far on silkworm pupæ, even the highest doses of hormone have failed to cause the reappearance of any trace of larval characteristics.

Extracts prepared from petroleum ether have been found active when applied topically to the outside of the pupal cuticle. The result is an insect which is a mixture of pupa and adult. Individuals of this type show a low viability and soon die without completing their development. Therefore, in addition to the theoretical interest of the juvenile hormone, it seems likely that the hormone, when identified and synthesized, will prove to be an effective insecticide. This prospect is worthy of attention because insects can scarcely evolve a resistance to their own hormone.

A Humoral Stimulus to the Secretion of the Brain-Hormone in Lepidoptera

IN insects, growth and moulting depend on the activity of a number of endocrine organs. It is known that a group of neurosecretory cells in the brain secrete a hormone which induces the thoracic glands to produce another hormone, and that this second hormone probably stimulates growth of the body through yet other links[1]. However, the processes which precede and control the initial secretory activity in the brain are still largely unknown. Lees[2] has set out evidence in favour of the theory that secretion of the brain hormone is induced by nervous stimuli. On the other hand, Andrewartha[3] thought that the brain might respond to a humoral stimulus linked with nutrition.

The results reported here of some experiments done with the vine-moth *Phalaenoides glycine* Lew. (Noctuidae) do not seem to fit into Lees's theory. This insect over-winters as a diapausing pupa, but may have several non-diapausing generations during summer. At 25° C. in non-diapausing pupæ the brain did not appear to secrete the hormone necessary for adult development until 3–7 days after pupation. Removal of the brain before this critical period produced 'permanent' pupæ which survived for up to ten months. Unoperated control pupæ became adult in about three weeks.

'Permanent' pupæ were prepared by removing their brains less than 24 hr. after pupation. They were divided into two groups. In one group each of the pupæ received one or two brains from larvæ of *P. glycine* which had spent less than 24 hr. in the final instar and had not eaten any food since the previous instar. The larval brains were implanted immediately after the host's brain had been removed. In the other group of pupæ nothing was implanted. It seems safe to assume that the larval brains implanted in this experiment had not been stimulated before the operation, because they had just completed a secretory cycle and previous observations had shown that final instar larvæ needed at least eight days of 'obligatory' feeding to induce pupation. Seven out of twenty-four of the pupæ with implanted brains became adult within 40 days. Of twenty-two brainless controls, none became adult.

This suggests that in *P. glycine* the stimulus to the brain is humoral rather than neural. The possibility of stimulus through stray regenerating nerve fibres cannot be ruled out; but it seems unlikely. The condition of the pupal body which induced neurosecretion was not transient but persisted for at least seven months. This was shown by implanting young larval brains into 'permanent' pupæ at ten days, four months and seven months after pupation. One or more in each class became adult.

Williams[4] implanted the brains of young larvæ of *Platysamia cecropia* into brainless diapausing pupæ and obtained some adult moths. He gave no information on the period of 'obligatory' feeding; but it is probable that these brains had not been stimulated by their own bodies and that his positive results are also explicable in terms of a humoral stimulus. The evidence presented in this communication suggests that in some insects humoral factors alone may be sufficient to stimulate the cerebral neurosecretory cells. In *Rhodnius prolixus* and *Bombyx mori*[2] the central nervous system appears to play an essential part; but it is possible that even in these species nervous control is superimposed on a humoral mechanism.

Thanks are due to Dr. H. G. Andrewartha of this Department for advice, guidance and criticism. This work was carried out during the tenure of a studentship of the Commonwealth Scientific and Industrial Research Organization and of a grant of the University of Adelaide.

Production of Human Antiglobulin Reagent in Sheep

THE human antiglobulin reagent described by Coombs, Mourant and Race[1] was prepared in rabbits. Later, Eyquem (personal communication), Hill and Haberman[2] and Dunsford (personal communication) produced reagents in goats, and Eyquem (personal communication) in donkeys. I have tried to produce a reagent in a variety of animals, including rabbits, hens, sheep and the horse. Rabbits, of course, have been used in many laboratories; but it seemed it would be an advantage if an animal could be used from which more serum was available when immunization was satisfactorily completed. Sheep were found to be satisfactory animals.

Intramuscular injections of alum-precipitated serum were given and the animals bled at various intervals. The sheep serum was tested as an absorbed and as an unabsorbed diluted reagent against cells sensitized with the incomplete forms of anti-D, anti-K, anti-Fy^a, anti-A, anti-Jk^a and anti-Le^a. Direct tests were also carried out with cells from cases of acquired hæmolytic anæmia and with cells obtained from the cord blood of babies affected with hæmolytic disease of the newborn.

These results were compared with those obtained when standard antisera prepared in rabbits were used, and the results were very satisfactory. Strong positive results were given using the sheep antiglobulin serum. When the absorbed serum was used, if weakly sensitized cells were used as test cells, zoning was detected.

Many examples of each of the antisera listed above were used in the tests, and the appropriate antibodies were readily detected, the most difficult being anti-Le^a and anti-Jk^a. These antibodies require to be freshly collected or to have suitably selected normal fresh serum added to them to give optimum reactions. Certain examples of this antibody series do require a more concentrated antiglobulin reagent than that which is normally used in routine work. Crawford, Cutbush and Mollison[3] consider that anti-Le^a antibodies are of the alpha- and beta-globulin type and that this is the reason why a more concentrated antiglobulin reagent is required. It seems probable that some examples of anti-Jk^a antibodies fall into this class.

These difficulties, of course, are not confined to sheep antiglobulin reagents, but occur with reagents prepared in other animals. More information is required about the action of anti-Le^a and anti-Jk^a and the best methods for their detection and use.

The reagent was tested for avidity, for freedom from false positive results and for efficacy in routine use. In all these tests it was as good as many reagents prepared in rabbits, with which it was compared, and especially noteworthy was its freedom from false positive results.

Full details will be published elsewhere. I wish to thank the Evans Biological Institute, Runcorn, for providing the sheep for injection.

Cytoplasmic Inheritance

FROM the point of view of cell physiology we can distinguish two distinct levels of gene action. One level is that at which the synthesis of macromolecules is controlled. The second level is that of the organization of macromolecules into physiological units. In differentiated cells it seems probable that the synthesis of macromolecules is normally under rather direct control of Mendelian (chromosome) genes, whereas their organization into functional units is often largely controlled by cytoplasmic inheritance (for reviews, see Lwoff[1], Ephrussi[2], Michaelis[3] and Danielli, Lorch, Ord and Wilson[4]).

Many authors speak simply of cytoplasmic inheritance, without inquiry into its mechanism. Others refer cytoplasmic inheritance to plasmagenes. The use of the term 'plasmagene' necessarily involves associations with chromosome genes; this is undesirable, since the determinants of cytoplasmic inheritance usually differ in their nature and function from chromosome genes. I wish therefore to suggest that a new term should be used for those determinants of inheritance which are themselves organizations of molecules or of processes, and are self-reproducing. Such determinants include centrosomes, chloroplasts, kinetosomes, kinetoplasts and the cytochrome oxidase-containing granules of yeasts. Many such cytoplasmic bodies differ from chromosome genes in containing no deoxypentose nucleic acid, and in having no function of controlling the synthesis of macromolecules. On the other hand, they are self-reproducing, do not arise spontaneously, and control (and may perform) at least one cellular function. They are in fact the homeostatic units responsible for controlling those activities of a cell which are functions of organizations of macromolecules. They are thus self-reproducing homeostatic units, the specific properties of which can only be defined at the level of organizations of macromolecules. I wish, therefore, to suggest, as a first attempt at finding a suitable term for these determinants, the word *homeostat*. A homeostat may be defined as an organization of macromolecules, or of processes, which is self-reproducing and which may also (and usually does) determine and control the expression of one or more characters in a cell lineage.

To illustrate a major possible usage for such a term, we may refer to differentiation. Then differentiation may be regarded as the development of a variety of homeostats which are the characteristic determinants of different cell lineages, against the constant background of Mendelian genes carried by the chromosomes. All cell lineages in one animal normally carry the same chromosome genes, and each cell lineage carries a distinct set of homeostats.

By using quite different terms for genes and for homeostats, it becomes much easier to think of them independently, and to avoid unjustified and unnecessarily limiting associations.

Diurnal Rhythms of Activity in Terrestrial Arthropods

ATTENTION has recently been directed to the close parallel that exists between the rhythm of biting activity in certain East African mosquitoes and the bimodal flight activity of the Trichoptera, and it is suggested that in insects showing abrupt 'eo-crepuscular' activity the control is mainly microclimatic[1]. If this is so, the diurnal rhythm must be largely 'exogenous' in nature and would not persist under constant environmental conditions as 'endogenous' rhythms do. The majority of animal species, however, show a combination of both types, and such periodicity is designated 'composite'. This type of rhythm occurs in cockroaches and has recently been shown to have a neurosecretory basis[2].

Even innate endogenous rhythms are regulated by changes in environmental factors such as light, temperature and humidity ; but as they are not a direct response to them, such factors have been referred to by me as 'clues', a term which appears to correspond with the German 'Zeitgeber', and their importance lies in the maintenance of rhythm and in keeping it in phase with the environment[3]. Under natural conditions there are probably several 'clues' active at the same time, one of which is generally the ruling factor of an animal's periodicity. In most cases light intensity is the factor that sets its mark on activity as a whole, while others, such as temperature, humidity or wind, which may have even greater ecological importance, are, in the main, responsible for the degree of intensity. Thus in wood-lice, although a composite diurnal locomotory rhythm is synchronized with the environment by alternating light and darkness[4], the intensity of nocturnalism in different species is correlated with the ability to withstand water-loss by transpiration[5].

A Filamentous Saprophyte from Wookey Hole Caves

AN unusual branched filamentous organism, superficially resembling a water mould, was found growing submerged in complete darkness, by Dr. R. E. Davies, in the ninth cavern of Wookey Hole, near Wells, Somerset, on December 11, 1955. The plant was attached to the insulation of a reel of cable deposited in the caves on June 28, 1953, under about 10 ft. of water.

The felt consisted of a tangled mass of large septate, branching filaments (10–30μ in diameter), many of which were coated with ferric hydroxide in the form of strands (Fig. 1). Branches arise just beneath the cross-walls as in *Cladophora*, and taper to fine septate threads (*c*. 4–7μ across). There was no evidence of pigmentation or of the presence of chromatophores either in the original material or in the organism after culture in daylight for more than three months. The cytoplasm contains minute granules and the cells of the older filaments are extensively vacuolated (Fig. 2). The presence of nuclei has not been established although material has been stained with acetocarmine, hæmatoxylin and by the Feulgen technique. Treatment of the cell wall with chlor-zinc-iodide did not give the typical cellulose reaction, a yellow-brown coloration resulting. Septate hyphal-like threads emerge from broken ends of the filaments, and, when cells of the large filaments die, the protoplasts of the adjacent cells often grow through into the empty cells (Fig. 3), where they may fuse with one another. Cross-connexions may develop between young filaments. No reproductive structures have been seen. Pure cultures of the organism have been obtained on potato extract agar, and the original material has been also maintained in liquid inorganic media.

Only one previous record of an apparently algal saprophytic organism of a branching filamentous type (*Saprochaete saccharophila* Coker and Shanor[1]) is known to us. The specimen from Wookey Hole differs from *Saprochaete* in a number of morphological features and, among the algae, resembles members of the Cladophorales rather than of the Chætophorales. The nutrition and certain morphological characters seem to indicate fungal affinities ; but the very large cell size is uncommon in fungi. Attempts are now

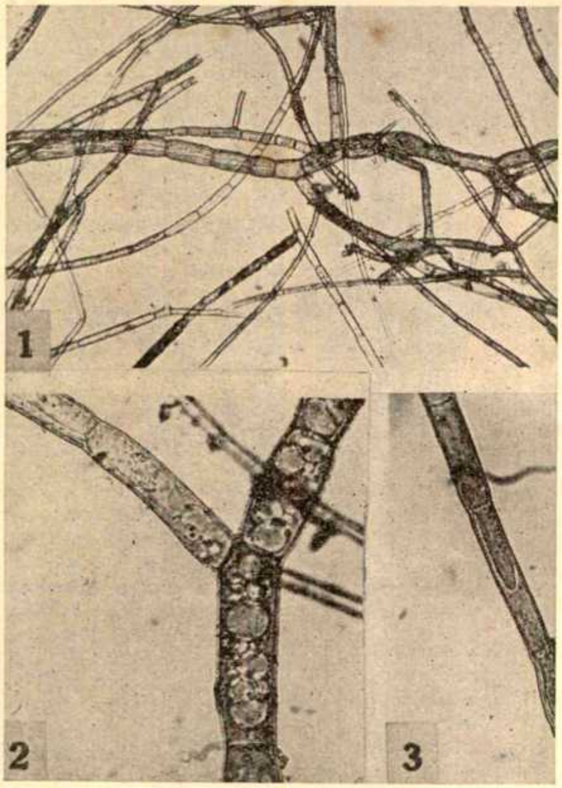

Fig. 1. Photomicrograph showing the range of size of the filaments, the mode of branching and a strand-like coating of ferric hydroxide on the largest filament. (× 90.) (2) The cells contain conspicuous rounded vacuoles and minute granules. (× 360.) (3) The peg-like ingrowth from one cell into the adjacent cell is clear. (× 360)

being made to culture the organism on various media in the hope that further investigation will throw light on the metabolism and systematic position of this interesting plant.

Occurrence of Apiose in *Hevea brasiliensis*

FRUCTOSE, glucose, quebrachitol, mesoinositol, and (−)-inositol have been detected in the free state in *Hevea* latex serum, and glucose, galactose, mesoinositol, and an unknown sugar (probably a ketose) were obtained on hydrolysis of a latex lipid fraction[1]. The work reported here is an examination of *Hevea* bark tissues for reducing sugars, and, in view of the common 5-carbon branched skeleton unit of the isoprenoid compounds, particular interest lay in the detection of branched-chain sugars.

The plant material used was whole bark, which had been collected fresh and dried at 90°. A powdered sample (50 gm.) was boiled under reflux for 4 hr. with 0·2 N sulphuric acid (500 ml.) and filtered. After saturating the filtrate with barium carbonate, and filtering, the solution was concentrated under reduced pressure to a syrupy residue. This was extracted with boiling 95 per cent ethanol (100 ml.), and the insoluble material removed on the centrifuge. The ethanol was distilled off, and the resulting syrup boiled for 5 min. with water (50 ml.) and animal charcoal (2 gm.) and filtered. After concentration, and extraction with boiling ethanol, as before, the solution was finally concentrated to a thick syrup.

Chromatography of this product was carried out on Whatman No. 1 paper with a solvent system of n-butanol–water–ethanol (50 : 40 : 10 by vol.) in runs of up to 55-hr. duration. Eight compact and fully separated spots were stained by silver nitrate reagent. The fastest-moving component (R_F 0·28) was of greatest interest, since this agreed exactly with an authentic specimen of apiose prepared by hydrolysis[2] of parsley apiin (Merck). By the use of specific spray reagents, and variation of solvent system in one- and two-dimensional runs with comparative mixtures of known compounds, it was concluded that the remaining spots were due to maltose, galactose, glucose, fructose, quebrachitol, mesoinositol, and possibly xylose. Only glucose, fructose and quebrachitol could be detected in water extracts of bark. In order to characterize further the substance resembling apiose, a preparative fractionation of the sugar mixture was carried out on a column of cellulose powder[3]. The authentic apiose, which contained about 5 per cent glucose impurity, was fractionated in the same way. A fraction (I) isolated from the bark mixture yielded 11 mgm. of syrup. This was indistinguishable from apiose when chromatographed separately and in mixtures in a wide range of solvents. With high concentrations of fraction I a faint spot, stained red by aniline hydrogen phthalate, was visible immediately behind, but completely separated from, the suspect apiose spot. Apiose, while not yielding furfuraldehyde when treated with acid, did give faint colours (yellow-brown) when sprayed with aniline hydrogen phthalate or p-anisidine hydrochloride. Identical colours were given with the corresponding component of fraction I.

Phenylosazones were prepared from fraction I and apiose, and recrystallized from aqueous ethanol. These melted at 154°–156°, and the mixed melting point was unchanged. Thus, it was concluded that the main component of fraction I was apiose.

This sugar has the same carbon structure as the skeleton unit of isoprenoid substances, and it has been suggested[4] that apiose could give rise to simple terpenes by condensation and reduction. Such a reaction seems unlikely , but the presence of apiose in *Hevea* does suggest a possible metabolic link between the sugars and the 5-carbon intermediates of isoprenoid synthesis. An interesting connexion was noted between parsley, from which apiose is most readily obtained, and several rubber-producing plants. The carbon tetrachloride extracts of *Hevea* bark, *Taraxacum kok-saghyz* root and *Taraxacum officinalis* root, were saponified, and extracted with ether. After removal of ether each of these extracts possessed the odour characteristic of fresh parsley.

I am indebted to the Dunlop Rubber Co., Ltd., for permission to publish this note.

Association of a Species of *Itersonilia* with Parsnip Canker in Great Britain

A SPECIES of *Itersonilia* Derx was isolated by Wilkinson[1] in 1952 from cankers on parsnip roots in the United States. He did not publish a species identification, nor did Sowell[2] in a later note on the fungus; but cultures were afterwards lodged by Sowell at the Centraalbureau voor Schimmelcultures, Baarn, under the name *I. perplexans*. Wilkinson demonstrated the pathogenicity of the fungus and showed that it was also responsible for lesions on the leaves. I have made similar observations in Britain.

The fungus was first obtained, with five others, in the autumn of 1954, from tissue taken from the inner margins of parsnip canker lesions. Isolations were made by surface sterilizing, washing and planting small pieces of infected tissue on prune agar. During the winter of 1955–56, several isolates of each of these fungi were tested in the laboratory for pathogenicity to parsnip roots. Of the six fungi tested, only one was found to infect both wounded and unwounded parsnip tissue and this fungus was identified as a species of *Itersonilia* Derx. The Commonwealth Mycological Institute confirmed this identification and reported that in many respects the fungus resembled *I. perplexans*.

During the winter and spring of 1955–56, further isolations were made from cankerous lesions by the spore-dropping technique used by Wilkinson[1]. Pieces of diseased tissue were attached to the lid of a Petri dish with 'Bostik' and suspended over a plate of prune or Waksman's egg albumen agar[3]. When incubated at 21° C., colonies of *Itersonilia* frequently developed on the agar from ballistospores ejected from the pieces of diseased material. Inoculation of parsnip roots in the laboratory with several of these cultures resulted in rotting, similar to that produced by the 1954 isolates, and re-isolation by the spore-dropping technique from the artificial lesions established the pathogenicity of the fungus.

Itersonilia has been obtained from two types of lesion both of which are quite common in the field. The first type was dark brown to black in colour and extended 2–3 mm. into the tissue of the shoulder. Where the surface tissues were ruptured, the underlying parenchyma usually appeared slightly purplish. In the second type the surface of the root was invariably ruptured. The exposed parenchymatous tissue was light brown to orange-brown in colour, but frequently included areas which were darker brown and rotted. When inoculated into parsnips, the fungus produced lesions only of the first type. Thus although it was clearly the cause of this type of lesion, the significance of its association with the other type remains to be determined.

The fungus has been obtained from parsnips grown at the National Vegetable Research Station and at two farms in Buckinghamshire and one in Kent.

Leaf infection of young plants has been demonstrated by single or successive sprayings of a macerated mycelial suspension on to the foliage of potted parsnips in the glasshouse. The lesions developed within six days and appeared as silvery green patches approximately 1 mm. diameter or as larger patches, each consisting of a necrotic centre surrounded by a light-green halo. The re-isolation of *Itersonilia* from the lesions by the spore-dropping technique confirmed that the lesions were caused by the fungus.

The present work fully supports that of Wilkinson and indicates that a fungal pathogen hitherto unreported in Great Britain is associated with parsnip cankers in Britain. Its occurrence is apparently widespread; but further work will be necessary before it can be determined whether *Itersonilia* is responsible for most, or only part, of the somewhat variable symptoms on parsnips at present grouped under the term 'canker'.

Thanks are due to Dr. M. B. Ellis, of the Commonwealth Mycological Institute, for the identification of the culture of *Itersonilia*.

Control of Coffee Berry Disease in Kenya

A DISEASE of coffee berries, attributed to a form of *Colletotrichum coffeanum* Noack, was first described from West Rift areas of Kenya in 1922[1]. It caused extensive losses and the abandonment of coffee cultivation on many estates, and although by 1939 selections of coffee which showed some degree of resistance had been made, direct attack with a considerable range of fungicides had led to little, if any, control of the disease. A detailed account of the disease and of investigations up to 1950 has been published[2].

Previous work[1] had shown that disease symptoms could be reproduced by the inoculation of the pathogen into wounded or detached berries; but the degree of pathogenicity was not established until symptoms were produced using spore inoculum without wounding[3].

In 1951, the disease appeared for the first time in the East Rift coffee area, the higher-altitude zones being affected. As this area produces the greater proportion of the Kenya coffee crop, investigations on the disease received a considerable impetus. Further fungicide trials were carried out using 'Perenox', phenyl mercury, 'Fixtan', 'Tulisan' and calcium sulphamate; but no degree of control was observed.

Early in 1955, the effects of a wide range of fungicides were tested on an estate in the East Rift area. Fifteen treatments were compared using six replications of a balanced, incomplete block design with three plots per block. Each block consisted of one head of three multiple-stem trees, the trees selected having three equal heads each. In this way, individual tree variations in susceptibility and yield could be statistically controlled. The following fungicides were applied at monthly intervals during the long rains (March–May) and the short rains (November–December), giving a total of five applications; 'Perenox', 'Karathane', 'Verdasan', 'Fermate', 'Zerlate', 'Dithane', 'Actidione', 'Captan', 'Glyoxalidine' and calcium sulphamate. In addition, 'Perenox' was applied at fourteen-day intervals throughout the season.

Only 'Perenox', applied at fortnightly intervals, and 'Verdasan' gave an effective control of the disease. No control could be detected when 'Perenox' was applied at the same frequency as 'Verdasan'. As fortnightly fungicidal application is undesirable, 'Verdasan' affords the best possibility of control as yet. In view of the earlier failure to obtain direct control of the disease with fungicides, the importance of these results is considerable.

Repeated calcium sulphamate treatments at 1, 3 and 6 per cent were all found to be highly phytotoxic although previously a single application at 1 per cent had not produced any adverse effects.

A laboratory technique for testing fungicides on detached berries has given results comparable with those of the field trials. Preliminary tests using 'Griseofulvin' at a concentration of 880 p.p.m. have given results similar to 'Verdasan'.

Further field trials are in progress.

Suppression of the Sprouting of Potatoes by the Vapour of Alcohols

THE use of a growth-inhibiting vapour for the commercial suppression of the sprouting of potatoes offers certain advantages over the employment of suppressant dusts, though these have been used with success. In particular, application of the treatment can be delayed until signs of sprouting are observed —which in some years, when the onset of sprouting is late, can lead to an appreciable saving in cost— and the farmer need not decide whether or not to employ a sprout suppressant until some time after harvest, when he may be in a better position to know whether it is likely to be advantageous to store his potatoes late. Attempts have therefore been made to use a number of gases and vapours, as, for example, ethylene[1].

The fact that the volatile metabolic products of potato tubers will completely inhibit their sprouting, if allowed to accumulate in the absence of carbon dioxide, led to the discovery that the vapour of *n*-amyl alcohol was a very effective sprout inhibitor[2]. Ethyl alcohol vapour had previously been described as retarding sprout growth[3]. Later, the vapours of both *iso*-amyl and active amyl alcohol were found to be effective at concentrations of about 1 mgm./l., and commercial amyl alcohol (a variable mixture of the *iso* and active alcohols) was used successfully on the sixteen-ton scale[4]. It seemed possible that alcohol vapours in general might retard sprout growth, and the results of a number of tests, given in the accompanying table, seem to confirm this. In most cases no attempt has been made to extend the tests to cover a number of concentrations, although this has been done to a limited extent with nonyl alcohol, which has shown promise of being applicable on a commercial scale[5].

Mr. R. J. Gibbs helped with the work described here. It was carried out as part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Carbon Dioxide Injury and the Presence of Succinic Acid in Apples

RECENT work in this Laboratory[1] has shown that succinic acid may not only inhibit oxidative processes, as shown by earlier workers[2], but also it may be actually toxic to plant material. Succinate supplied to respiring disks of apple peel (in a suitable buffer system at pH 4·1) at concentrations greater than about 0·025 M reduces oxygen uptake and carbon dioxide output, and in a comparatively short time the respiration falls practically to zero and the tissue becomes brown and 'dead'. At this external concentration of succinate the internal concentration is less than 0·001 M.

In normal healthy apples we have found succinic acid only occasionally and in trace amounts in either the peel or the pulp. This does not necessarily mean

Table 1. THE QUINIC, SUCCINIC AND MALIC ACID CONTENT OF THE PULP OF APPLES STORED UNDER VARIOUS ENVIRONMENTAL CONDITIONS

Treatment	Temp.	Days	Quinic (mgm./100 gm. fresh wt.)	Succinic (mgm./100 gm. fresh wt.)	Malic (mgm./100 gm. fresh wt.)	Condition of tissue
Air	37° F.	31	84·0	—	1,221·7	No damage
10 per cent CO_2	37° F.	31	87·5	6·35	1,228·5	No damage
20 per cent CO_2	37° F.	11	89·5	21·0	1,224·5	CO_2 damage
Air	50° F.	90	84·0	Trace	907·8	No damage
20 per cent CO_2	50° F.	90	96·3	1·10	879·5	No damage

that succinate is not a normal intermediate metabolite in the fruit; its turnover-rate may be so high as to prevent accumulation. It was noticed, however, that on paper chromatograms of the acid fractions from apples suffering from incipient carbon dioxide injury (a physiological disease of fruit stored in hypernormal concentrations of carbon dioxide, and resulting in the death of the affected tissue), there appeared a spot corresponding in position to that of succinic acid. A sample of the acid giving this spot was isolated from an extract of 1 kgm. of affected fruit and it proved to be a dibasic acid having an analysis of: C, 40·6; H, 5·3; O_2 (by difference) 54·1 (succinic acid = C, 40·7; H, 5·1). It melted at 185° C., and when mixed with authentic succinic acid produced no lowering of the melting point. The *p*-nitrobenzyl ester had a melting point of 87·5° C. A similar derivative from authentic succinic acid had a melting point of 88·0° C.

Determinations of the amount of the various organic acids present in fruit stored in air and in various concentrations of carbon dioxide at 3° C. and 10° C. (apples are more susceptible to carbon dioxide injury at lower, than at higher, temperatures) were made and the extent of carbon dioxide injury in affected fruit was recorded. The results are given in Table 1.

These results show that carbon dioxide injury is accompanied by an increase in succinic acid in the tissue. It appears that an abnormality of metabolism is induced in the tissue by hypernormal concentrations of carbon dioxide in the surrounding atmosphere which results in an accumulation of succinic acid. This, in turn, it is suggested, kills the tissue.

Further details of this work and its wider implications will be presented elsewhere.

Nitrogenous Reserves of Apple Trees

WHEN young apple trees assimilate nitrogen, reserve materials are generally laid down in the tissues of the stem and root[1]. Only part of these nitrogenous reserves can be extracted from the stem by exhaustive treatment with 70 per cent (v/v) aqueous ethanol, and a study has recently been made both of the nature of the reserves and of their extraction from the tissues by different solvents.

Amino-acids were separated chromatographically from the tissue extracts by a modification of the method of Moore and Stein[2,3], using ion-exchange resins 'Dowex 50' or 'Zeo-Karb 225'. In this way, arginine and asparagine were identified as the chief nitrogenous reserves; together, they represented 70–80 per cent of the total soluble nitrogen which could be extracted. Arginine alone accounted for more than 60 per cent of the soluble nitrogen in a typical analysis, and, although most of the amino-acids commonly found in plant tissues were present, none of them exceeded 1 per cent of the total soluble nitrogen.

It has also been shown that a large part of the arginine is bound in the tissue, so that it cannot be readily extracted with 70 per cent ethanol. Successive treatments of the finely divided tissue with hot or cold ethanol gave apparent completion of extraction, since the final extract yielded less than 1 per cent of the soluble nitrogen. Nevertheless, further treatment with hot water removed additional soluble nitrogen, amounting to 20–30 per cent of the total. The analyses, summarized in Table 1, indicated that large quantities of arginine were present in the water extract, despite the previous exhaustive treatment with ethanol.

Table 1. EXTRACTION OF APPLE STEM TISSUE WITH 70 PER CENT ETHANOL FOLLOWED BY WATER

	Total nitrogen in extract (per cent)	
	70 per cent ethanol	Water
Arginine	62·0	66·0
Asparagine	15·0	0·3–1·0
Glutamic acid	1·0	
Serine	1·0	
Histidine	0·3	
γ-Amino-butyric acid	0·2	
Alanine	0·2	
Valine	0·1	
Other α-amino-nitrogen	0·3	
Ammonia	0·8	0·6
Other soluble nitrogen	19·0	32·0

Although asparagine and some of the amino-acids were effectively extracted by aqueous ethanol, it is evident that this solvent should be used with caution for quantitative studies of the nitrogenous constituents of plants. In the present experiments, some direct evidence has been obtained that arginine, when added in ethanolic solution to apple stem tissue, is removed from solution, probably owing to reaction with acidic components. Hot water, or sodium chloride solution buffered at *p*H 7, as used by Danielsson[4], appears to be much more effective than aqueous ethanol for extracting the dialysable nitrogenous constituents, particularly when large reserves of arginine may be present, as in apple stems.

A full account of the investigation will be published elsewhere.

Interaction between Nickel and Calcium in Plants

In the course of an investigation into the toxic effects of nickel on plants, it was found that the calcium content of nickel-toxic oat plants was consistently higher than that of healthy plants[1]. The absorption of other major nutrients, on the other hand, was reduced in the presence of nickel. In contrast, tomato plants showed a reduced content of all major elements, including calcium, when supplied with nickel in toxic amounts. The toxicity symptoms produced in both plants consist of chlorosis (of young leaves) accompanied by longitudinal necrotic striping (oat) or necrotic areas of the older leaves (tomato). Growth is reduced and root development arrested; the roots become brown, with poor secondary-root production.

To investigate whether the effect of nickel on calcium absorption occurs external to the root, in the root, or in the plant, a split-root technique has been applied using oat and tomato in solution culture and radiocalcium (calcium-45) to identify the origin of the calcium afterwards found in the plant.

Four treatments were employed: (1) Whole root system in complete nutrient solution containing labelled calcium; (2) as for 1, with the addition of 2·5 p.p.m. nickel (as the sulphate); (3) root system divided between two compartments containing (*a*) complete nutrient solution and (*b*) complete nutrient solution with part of calcium as calcium-45; (4) as for 3, except that the (*b*) compartment contained 2·5 p.p.m. nickel.

Seedlings were raised in sand and transferred to the differential treatments, where growth was allowed to proceed for several weeks during which time mild symptoms of nickel toxicity appeared. Excessive reduction in growth due to nickel did not take place, although plants with split-roots were slightly smaller than those left undivided. At harvest, yields were recorded and plants divided into young and old leaves, petioles (tomato only), stems and roots. Major elements, iron and nickel, were determined in the dry matter. Calcium was precipitated as the oxalate for radioactive assay and the results used for calculating calcium absorbed after the start of the differential treatments, and further, to identify the calcium absorbed from the (*b*) compartments. Table 1 summarizes the main findings for young leaves.

For convenience, an increase in calcium content following the addition of nickel is hereafter referred to as positive calcium effect. Thus for oats, a positive calcium effect is found in both whole and split-root treatments, the magnitude of the effect being greater in the latter case. Tomatoes show a negative effect for plants with undivided roots and a positive effect where the roots were split. In comparing treatments 1 and 2, radioactive calcium analysis confirms this greater and lesser calcium uptake by oats and tomatoes respectively.

Table 1. Analysis of Young Leaves

		1	2	3	4
		Whole root		Split root	
		Healthy	Ni-toxic	Healthy	Ni-toxic
Ca (per cent in dry matter)	Oats	0·68	0·89	0·71	2·97
	Tomatoes	2·37	1·21	1·28	5·16
Per cent total Ca as ^{45}Ca labelled Ca	Oats	88·0*	95·0	69·0†	27·0
	Tomatoes	90·0	68·0	19·0	8·0
Ni (p.p.m. in dry matter)	Oats	—	60·0	—	49·0
	Tomatoes	—	106·0	—	25·0

* $\frac{\text{Ca absorbed after transfer}}{\text{Ca in seedling + Ca absorbed}}$

† $\frac{\text{Ca absorbed through } b \text{ roots only}}{\text{Ca in seedling + Ca absorbed through both sides of root system}}$

The relative uptake of calcium through the 'no-nickel' and the 'nickel' half-roots (*b*) can be deduced from a comparison of treatments 3 and 4. Compared with the earlier results for the nickel–calcium interaction, radioactive analysis yields the additional information that for both plants the greater part of the increased calcium content of the leaves was absorbed through the 'no-nickel' side of the root system. As would be expected, the nickel content of the leaves was reduced in the treatments in which nickel was supplied to only half the root system.

The injured appearance of nickel-toxic roots seems to provide a valid explanation for the reduced leaf content of major nutrients; but it is difficult to advance reasons for the increased calcium absorption by such roots, as occurs for oats in treatment 2. In the plants of treatment 4, however, the bulk of the calcium in the leaves has been absorbed through the undamaged part of the root system (although a positive calcium effect still holds for the nickel-toxic part of the root system).

The present results suggest that two opposing phenomena may be occurring simultaneously when nickel is absorbed by plants: (1) the roots are damaged and the absorption and translocation of all major nutrients are reduced; (2) nickel in the leaves, by some unknown mechanism, increases the absorption of calcium by the roots. Different plants may show these effects in differing degree; in oats (2) will be predominant, while in tomatoes (1) predominates until nickel reaches the top of a plant which has not had all its root system exposed to nickel.

Preliminary experiments on a range of about twenty common crop plants have shown the majority to have a zero or a negative calcium effect similar to tomato. Among the cereals, maize shows a positive effect while wheat and barley do not. Certain root crops, namely, red beet, sugar beet and swede turnips, show a positive effect to a marked degree. These plants show an extreme susceptibility to nickel toxicity[2]; but other highly susceptible plants such as sunflower do not show a positive calcium effect. Reversal of the calcium effect from negative to positive has also been shown for mustard, by the split-root technique.

Until now, nickel, in common with other heavy metals supplied in excess to plants, has been recognized to interfere in iron metabolism[3-6]; the tacit assumption being that nickel or other heavy metal replaces iron in some complex essential to normal nutrition. The results now obtained suggest how nickel may affect processes within the plant. It seems possible that organic acid metabolism may be affected in nickel-toxic plants and that the state of solubility of calcium in the tissues may be altered by increased production of oxalic acid, for example.

A Model for manipulating Spirals

DARLINGTON[1] suggested that the coiling systems encountered in chromosomes are determined by spiral structures at the molecular level. Interest in the replication of spirals and in the separation in double spirals has been renewed recently[2-4] following proposals of helical structures for deoxyribonucleic acid[2] and for various proteins[5]. Some of the difficulties in the disentangling of twin spirals are simplified if the spirals are free to rotate about their axes, as may be demonstrated using the simple model here described.

The model consists of a stand holding parallel glass tubes which are free to rotate. In the model (Fig. 1) the stand is built of 'Meccano' parts and the three glass tubes are stoppered with rubber bungs into which small axles are inserted; they are linked together by a system of gears so that they all turn in the same direction at the same speed. Cotton tape is used for the spirals.

In the simplest manipulation, a single spiral wound about one rod, with its free end attached to an adjacent rod, is transferred to this rod when both are rotated. Other manipulations are based on this principle.

A double spiral on the centre rod, with free ends attached one to each of the side rods, is resolved into two single spirals by simple rotation, as shown in Fig. 1. If this process is thought to apply to structures of the Watson and Crick type, it would be necessary for new complementary chains to form simultaneously on the separating chains in order that two new helices be produced (Fig. 2*A*).

Two double spirals on a single rod can be separated one from another by a manipulation analogous to that shown in Fig. 1, or if the ends are appropriately arranged, they may be separated with exchange of partners as shown in Fig. 2*B*. With exchange of partners, double spirals of different constitution from the originals may be produced.

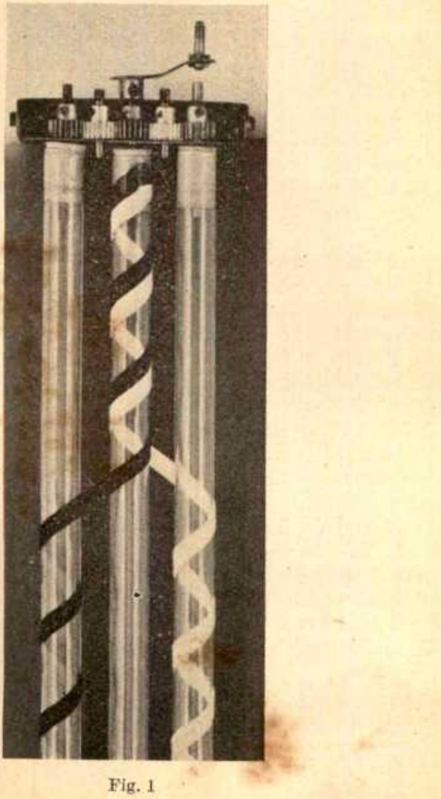

Fig. 1

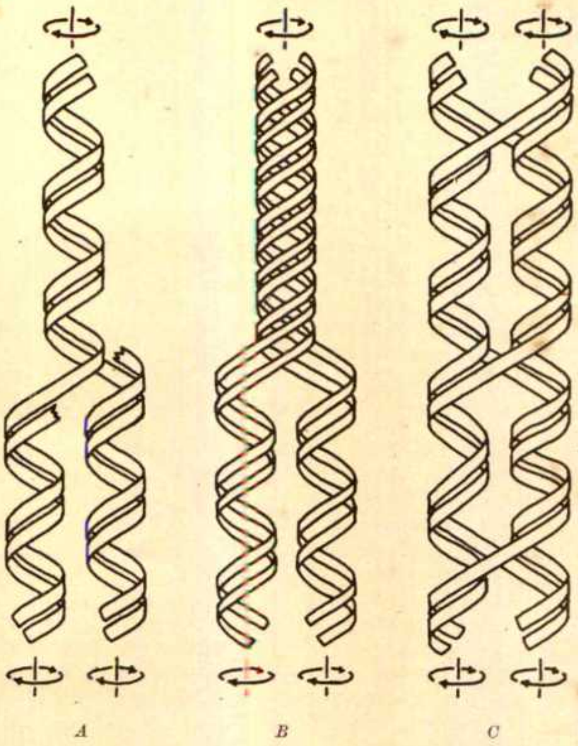

Fig. 2

Double spirals on adjacent rods may be made to change partners by simple rotation. Rotation may be interrupted and the free ends rearranged so that two or more exchanges can be effected (Fig. 2*C*). With the model it is possible to produce spiral systems resembling those postulated by Darlington[1] and others to account for crossing-over in chromosomes at meiosis. In Fig. 2*C*, where all possible exchanges between double spirals are shown, it may be seen that the pitch of the participating spirals must be varied slightly for this to occur. With non-flexible spirals, or with helices of the Watson and Crick type (formed of complementary chains), only certain exchanges are possible.

Continuous formation and separation of products from a template, as proposed by Dalgleish[6], can also be effected when the template and its partially formed products are spirals, by a similar process of rotation.

If it is considered that the original spiral in any of the foregoing examples is not free to rotate, the manipulations are still possible if the new or growing spirals are allowed to turn epicyclically about the original.

Adjacent spirals, with their axes close together so that one fits into the other, may also be manipulated by rotation. With systems of parallel spirals it is conceivable that an interlacing network or mesh may be formed by simple rotation.

Processes of the type here described are reversed when the direction of rotation is changed. With rotation some tendency to forward movement through the surrounding medium is to be expected. Apart from this, rotation permits a wide range of manipulation with a minimum of displacement in the structures concerned.

Financial assistance from the National Research Council of Canada is acknowledged.

Dislocation Models in 1902 ?

ONE of the attractive aspects of the theory of dislocations is the extent to which simple mechanical models may be used for demonstrating the basic concepts. Of such models the bubble raft assembly of Bragg is perhaps known to the widest lay audience, and, while it is probably stating the obvious to say that such a model is of real value only against the background of the *concepts* of dislocation theory, it is, nevertheless, very interesting to find published illustrations of such a model which date from 1902.

Figs. 1 and 2 are to be found on pp. 12 and 13 of the printed version of the Rede Lecture, delivered on June 10, 1902, by Osborne Reynolds and printed by the Cambridge University Press. Osborne Reynolds was professor of engineering in the Owens College, Manchester (later incorporated in the Victoria University of Manchester), during 1868–1905; during those years he completed the researches—on the mechanical equivalent of heat, on high-lift pumps, on lubrication and, of course, on streamline and turbulent flow in fluids—with which his name will always be associated. Reynolds's lecture for 1902 was entitled "On an Inversion of Ideas as to the Structure of the Universe" and, dealing as it does with the "granular structure of space", seems at first sight to be out of the main stream of contemporary scientific thought.

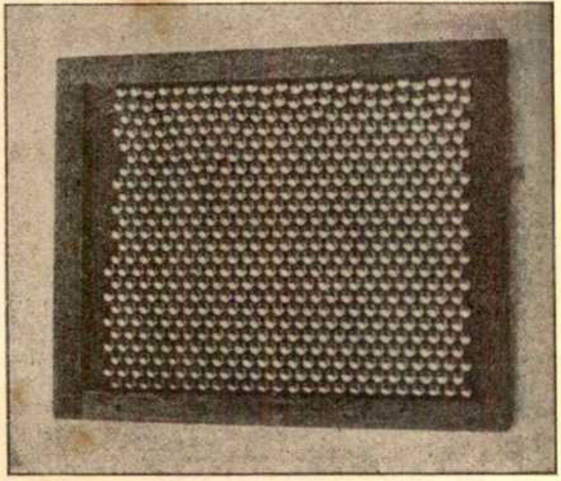

Fig. 1

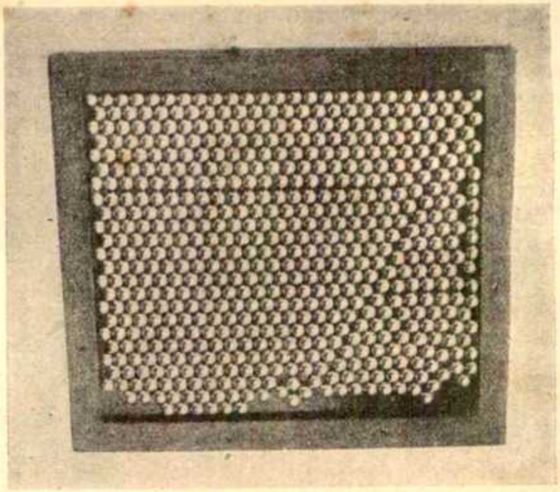

Fig. 2

A close study of the text of the lecture, however reveals that the dislocation models, far from being merely fortuitous, spring from a clear intellectual concept. Reynolds is at considerable pains to distinguish between the close-packed regular piling of Fig. 1, for which the application of a "strain" (*sic*) would not allow any change of neighbours in the array, and the abnormal piling of Fig. 2 in which because of the "abnormal gearing of the grains", an imposed "strain" may produce "relative motion of the grains and render(s) the medium elastic" (pp 12–13). (We should to-day prefer to write "stress" and "plastic" rather than "strain" and "elastic"; but the meaning is clear.)

It is evident that the correlation between Reynolds's models of regular and dislocated close-packed arrays and the bubble models of modern dislocation theory is no merely superficial similarity and, indeed both models stem from the same fundamental idea namely, the great strength which would be expected of a perfectly packed array of spherical particles That Reynolds's particles are not atoms in no way minimizes the validity of his basic concept.

The later pages of the lecture contain assertions on the nature of electricity and gravitation and on the propagation of light which read curiously to-day but there are phrases which bring one up with a start "Such motion has all the character of a wave in the medium ; and that is what the singular surfaces which we call matter, are—waves. We are all waves"

Finally, Reynolds returns to a demonstration of those extraordinary properties of sand which he had first described as "dilatation" in 1875. These phenomena, which were correctly ascribed to the different modes of packing of granular particles, have quite recently sprung into prominence again with the development of the new science of soil mechanics But to Reynolds they had a far wider significance and they led him to those speculations on the nature of the physical world which he described in the Rede Lecture. This, to him, was his greatest work, and when he sat to Collyer he chose to be portrayed holding a bowl of marbles ; perhaps he was right.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Lecturer in Physical Chemistry—The Registrar, Nottingham and District Technical College, Shakespeare Street, Nottingham (August 4).

Scientific Officer (male) at the Brown Trout Research Laboratory, Pitlochry, for duties chiefly connected with salmon research—The Establishment Officer, Scottish Home Department, Room 364, St. Andrews House, Edinburgh 1 (August 4).

Lecturer in Anatomy—The Registrar, The University, Manchester 13 (August 7).

Physicist (with a good honours degree or equivalent) at the National Coal Board's Coal Survey Laboratory in Cardiff, to initiate studies of the physical and mechanical properties of South Wales coal seams—The National Coal Board, Staff Department, Hobart House, London, S.W.1, quoting SS/335 (August 7).

Assistant Lecturer (preferably with interests in applied mathematics) in the Department of Mathematics—The Secretary, University College, Gower Street, London, W.C.1 (August 10).

Lecturer in Education at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, August 15).

Head (with high academic qualifications, preferably an honours degree in mining, practical mining experience, and teaching experience, preferably in a Technical College or a University) of the Mining and Geology Department—The Principal, Wigan and District Mining and Technical College, Wigan (August 17).

Research Assistants (2) (one with a good science degree in physics or physical chemistry) for investigations in selective flotation; (and the other with a degree in science or engineering) for research on the hydraulic transport of coal—The Registrar, The University, Leeds 2 (August 17).

Physicists and Mechanical Engineers (with a good honours degree or equivalent), to lead and engage in research work of national importance to increase coal production, concerned with fundamentals of methods of extracting coal from seams, strata support, conveying coal to the pit bottom and environmental conditions—The National Coal Board, Mining Research Establishment, Worton Hall, Isleworth, Middlesex, quoting SS/348 (August 21).

Professor of Psychology—The Registrar, The University, Reading (August 24).

Senior Lecturer (with experience in research and teaching in one of the following fields: mycology, algology or anatomy) in Botany at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 28).

Lecturer, Grade II (with an honours degree in engineering, together with practical engineering experience and an interest in research), in Mechanical Engineering—The Registrar, The University, Birmingham 15 (August 31).

Lecturers (3) in the Department of Pharmacy at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 31).

Senior Lecturer in Pharmacy at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31).

Senior Lecturer or Lecturer (with special qualifications in mining geology and geological surveying) in Geology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 31).

Chair of Geography at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 3).

Assistant Librarian (graduate) at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 6).

Lecturer or Assistant Lecturer (with qualifications in the realm of mathematical analysis) in Pure Mathematics—The Registrar, The University, Hull (September 15).

Reader in Mathematical Analysis at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 15).

Chair of Agriculture at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 30).

Reader in Pure or Applied Mathematics at the University of Oxford—The Secretary of Faculties, University Registry, Oxford (October 31).

Assistant (Grade A) to teach pure and applied mathematics; and an Assistant (Grade A) to teach physics—The Principal, Technical College, Queen Street South, Huddersfield.

Assistant (Grade B) in the Department of Mathematics, The Technical College, Bradford—The Director of Education, Town Hall, Bradford

Assistant Lecturer, Grade B (with an honours degree in mathematics and capable of teaching practical mathematics to the standard of the higher national diploma in engineering) in the Department of Mathematics, College of Technology and Commerce, Cardiff—The Director of Education, City Hall, Cardiff.

Assistant Physicist (Basic grade) at the Regional Radium Institute, Bradford—The Secretary, Royal Infirmary, Bradford.

Assistant to the Chief Technician—Prof. T. L. Bywater, Department of Agriculture, The University, Leeds 2

Assistant (with a first- or second-class honours degree in biochemistry or pure chemistry) in the Department of Biochemistry—The Secretary, The University, Edinburgh.

Bio-Physico-Chemical Technician (preferably with preparative and analytical experience), for research on nucleic acid—The Medical Research Council, Biophysics Research Unit, King's College, Strand, London, W.C.2.

Electrical or Mechanical Engineer (with a first- or second-class honours degree or equivalent qualification in electrical or mechanical engineering) at a Ministry of Supply Research and Development Establishment near Sevenoaks, Kent, to assist in the basic development of mechanical and electromechanical devices for projectiles and rockets—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.286/6A.

Graduate Chemists for fundamental and applied research in organic and physical chemistry—The Director of Research, British Rubber Producers' Research Association, 48 Tewin Road, Welwyn Garden City, Herts.

International Tin Research Council Research Scholar (honours graduate in chemistry or with equivalent qualifications) for work on mechanisms of reactions of organo-tin compounds—The Registrar, University College, Leicester.

Joseph Lucas Research Fellow (with an honours degree in metallurgy, chemistry or physics) to investigate the structure and metallurgical properties of electro-deposits—The Registrar, The University, Birmingham 15.

Lecturer (Grade II) in Physical Metallurgy—The Registrar, The University, Birmingham 15.

Lecturer in Agricultural Chemistry—The Principal, Seale-Hayne Agricultural College, Newton Abbot, Devon.

Lecturer (with a good engineering degree and some experience in industry and research) in Mechanical Engineering—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1.

Lecturers (2) (with experience in some field of applied physics, for example, electronics, solid state physics, vacuum technology, applied) in the Physics Department—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Physicist or Electrical Engineer (with an honours degree, some research experience, and a working knowledge of electronics) in the Physics Department, for work on a problem in ultrasonic propagation—The Registrar, University College, Leicester.

Research Fellow or Research Scholar (qualified in mineralogy and petrology) in the Department of Geology, to work on specific Antarctic problems and on material provided by the Falkland Islands Dependencies Survey—The Registrar, The University, Birmingham 15.

Senior Mathematics Master—The Headmaster, St. Peter's School, York.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Report of the Proceedings of the 1955 Conference of the Universities of Great Britain and Northern Ireland. Pp. 112. (London: Association of Universities of the British Commonwealth, 1956.) 3*s*. 6*d*. [75

Air Ministry: Meteorological Office. Professional Notes. No. 119. High Cloud Over Southern England. By R. J. Murgatroyd and P. Goldsmith. Pp. 20. (M.O. 524s). (London: H.M. Stationery Office, 1956.) 9*d*. net. [25

University of Cambridge: Department of Engineering. Report of the Head of the Department for the year 1954–55. Pp. 15. (Cambridge: The University, Department of Engineering, 1956.) [75

Empire Cotton Growing Corporation. Progress Reports from Experiment Stations, Season 1954–55. Kenya. By M. S. Hastie. Pp. 13. 9*d*. Northern Nigeria. Pp. 23. 9*d*. (London: Empire Cotton Growing Corporation, 1956.) [75

Scottish Home Department. Report for the year 1955 on the Royal Scottish Museum. By Dr. Douglas A. Allan. Pp. 16. (Edinburgh: Royal Scottish Museum, 1956.) [75

Discovery Reports. Vol. 28. Pp. 191–236: The Distribution of the Standing Crop of Zooplankton in the Southern Ocean. By P. Foxton. 17*s*. 6*d*. net. Title-page and Index to Volume 27. Pp. vii. 2*s*. 6*d*. (Cambridge: At the University Press, 1956.) [75

United Steel Companies Limited. Review of Progress 1955: Report for Employees. Pp. 28. (Sheffield: United Steel Companies Limited, 1956.) [75

Annual Report of the Royal Zoological Society of Scotland for the Financial Year ending 31st December 1955. Pp. 52. (Edinburgh: Royal Zoological Society of Scotland, 1956.) [105

Inorganic Qualitative Analysis: a Concise Scheme Using the Semi-Micro Technique. By H. Holness. Pp. 12. (London: Sir Isaac Pitman and Sons, Ltd., 1956.) 4*s*. [105

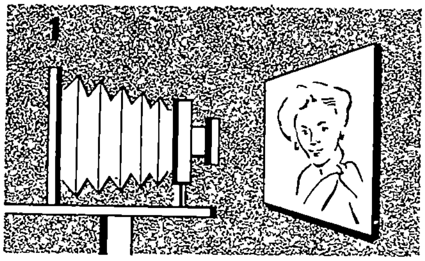
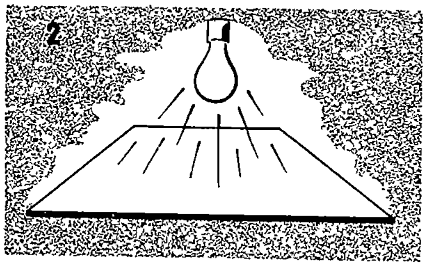
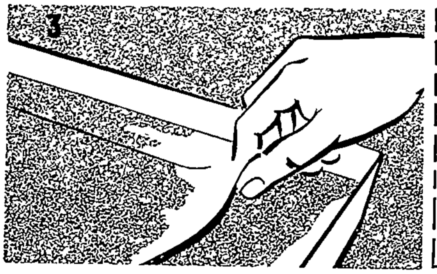
etters to the Editors :
Drift Experiments with Radioactive Pebbles.—C. Kidson, D. B. Smith and Prof J. A. Steers 257
Radiation-induced Changes in Reactivity of Bovine Fibrinogen.—Dr. Peter Rieser and Robert J. Rutman 257
Paper Electrophoresis of Rat Pancreatic Juice and Water-Soluble Proteins of the Pancreas.—Dr. Hanna A. Rothschild and L. C. U. Junqueira 258
Comparison of the Metabolic Stimulating Action of Aspirin and Thyroid.—W. D. Alexander and Miss K. W. M. Johnson 259
Synthesis and Biological Activity of a New Potent Analogue of Oxytocin.—R. A. Boissonnas, St. Guttmann, P.-A. Jaquenoud, J.-P. Waller, H. Konzett and B. Berde 260
In vivo Inhibition of Oxidative Phosphorylation of Rat-liver Mitochondria by 2 . 4 Dinitrophenol.—Dr. V. H. Parker 261
An Estimation of the Nature of Nucleoproteins by an Analytical Method.—A. Knobloch and Dr R. Vencrely 261
Serotonin and Connective Tissue.—Dr. G. Asboe-Hansen and O. Wegelius 262
A Substance promoting Hatching and Liberation of Young in Cirripedes.—Dr. D. J. Crisp 263
Production of Patulin in Apple Fruits by *Penicillium expansum*.—Dr. P. W. Brian, G. W. Elson and D. Lowe 263
Response of Animal Fibres to Acid Attack.—Dr. J. Menkart and Jeanne Detenbeck 264
Measurement of Mean Red-Cell Thickness by the Use of a Probability Function.—Dr. Eric Ponder and Dr Celia Barreto 265
Electrical Properties of the Plasma Membrane of Erythrocytes at Low Frequencies.—T. P. Bothwell and Prof. H. P. Schwan . . . 265
Energy-Relations of Mitotic Activity in Mouse Hair Bulbs.—Prof. W. S. Bullough and Edna B. Laurence 266
Assay of Spider Venom and Antivenene in *Drosophila*.—Dr. S. Wiener and Dr. F. H. Drummond 267
Histamine and Histidine in Excreta of the Blood-sucking Bug *Rhodnius prolixus*.—J. S. Harington 268
The Small Saphenous Vein as a Route for Intravenous Injection in the White Rat.—Dr. J. W. Everett and Dr. C. H. Sawyer . . . 268
A *p*H Gradient Agar Plate.—Dr. L. E. Sacks 269
Generic Status of *Glossopteris*, *Gangamopteris* and *Palæovittaria*.—K. R. Surange 270
Polyploidy and Radiosensitivity.—Dr. Alan D. Conger and A. Helen Johnston 271
Allium neapolitanum a Mixed Species.—Maria Kefallinou Hattersley-Smith 272
A Gene for Eyelids Open at Birth in the House Mouse.—Prof. J. H. Bennett and G. A. Gresham 272
An Adhesive for labelling Animals exposed to Sea-Water over Long Periods.—J. T Conover and M. E. Pierce 273
An Interfacial Barrier observed during Liquid–Liquid Extraction of Uranyl Nitrate.—Dr. J. B. Lewis 274
Relation between the Volume of a Liquid and its Internal Energy.—M. B. King and R. F. Strickland-Constable 275
Production of Carrier-free Cobalt-58 by Pile Irradiation of Nickel.—C. E. Mellish and J. A. Payne 275
Ca II Emission Lines in the Twilight Spectrum.—Prof. A. Vallance Jones 276
Sudden Absorption of Atmospherics due to Increase in Cosmic Ray Intensity.—Jules Aarons and William R. Barron 277
Representation of the Inelastic Deformation of Concrete by means of a Mechanical Model.—Dr. Henry J. Cowan 278
Creep in Coal at Room Temperature.—C. D. Pomeroy 279
Photographic Sensitizers in Gelatin.—G. Russell 280







Half-tone printing plates

with an ordinary studio camera

It is now possible to make half-tone printing plates with an ordinary sheet-film camera. 'Kodalith' Autoscreen Ortho Film has the half-tone dots incorporated in the emulsion, making process cameras and half-tone screens unnecessary.

Autoscreen Film can be used with pre-sensitized metal plates to make half-tone or combination line/tone plates for reproduction by office printing machines. Type matter and line drawings can be exposed at the same time as photographs or wash drawings.

Please send for details.

1. Make the normal detail exposure.
2. Flash with yellow light for contrast control.
3. Develop, with controlled agitation.

Kodalith

Autoscreen

Ortho Film

Kodak Limited, Industrial Sales Division, Kodak House, Kingsway, London, W.C.2.

'Kodalith' is a registered trade-mark.

TWENTY MILLION MEGOHMMETER

A direct reading megohmmeter covering from 300,000 ohms to 20 million megohms in seven decades. Internal test voltages of 85 v. and 500 v. are provided. The Model 29 is used both in the test room and in the manufacture of resistors, condensers, cables and dielectrics.

Other resistance measuring instruments in the E.I.L. range include:

Model 47A .. 100 microhms to 1,200 ohms.
Model 35 .. 200K to 200,000M
Model 31 .. 10^7 to 10^{14} ohms.

MODEL 29

E.I L. 23

INDUSTRIAL LEADERSHIP AND EDUCATION

FOLLOWING on an admirable article, "Trade Unions To-day", in the *Round Table* last December, the *Political Quarterly* devoted the whole of its January–March number to the examination of trade union problems, the contributors including some whose work, like that of B. C. Roberts in "Trade Union Government and Administration in Great Britain" and H. A. Clegg in "General Union", has already thrown fresh light on the problems that confront British trade unions in the Welfare State with its full employment. These studies testify o the need for change in the structure and even in he functions of the unions if they are to adapt themelves to serve effectively the needs of the day. They indicate no less emphatically that change and adaptation must come as a result of inquiry and pressure from within and not from without; though criticism from without can point to weaknesses and may advance constructive suggestions for reform, and it can help to create the understanding and limate of opinion which favour reform. The *Round Table*, for example, points out that the need to accept the duties and responsibilities of full employment falls upon the unions, and the passing of power into the hands of the trade unions is a fact that must be accepted. The utterances of responsible trade union leaders regarding automation itself have shown hat this is fully recognized by them, and that they are also aware that there are certain economic laws hat they must not neglect. But while the leaders may have shed doctrinaire views, they have as yet largely failed to induce their members to accept the responsibility for co-operating to the full extent with management in increasing the rhythm of production from which all demands must be met. This co-operation is a prime condition if we are to enjoy he benefits which automation offers, and it is a grave weakness in the report from the Department of Scientific and Industrial Research that it appears o lay the responsibility solely on the side of management. On the contrary, the challenge of prosperity which automation offers must be accepted by the rade unions also, and dealt with by them in terms of efficient production as the *Round Table* suggests.

The *Round Table* outlines a positive policy for the rade unions which contrasts sharply with the silence of the Department of Scientific and Industrial Research. The unions, it suggests, should co-operate o the maximum in acquiring industrial techniques to maintain increased standards of living, and should accept responsibility for introducing modern schemes of reorganization and reconstruction that mean re-deployment of labour, re-assessment of tasks and alterations in the status of jobs. The unions, it is emphasized further, should discard the untenable heory that we can enjoy increased standards of iving with decreased or static production-levels; but hey should insist on the maximum possible share for the producer in our expanding economy. Union policy and constitutions should be examined with the view of eliminating customs and practices which prevent work becoming easier and new production methods being adopted, and should insist on the elimination of malpractices of employers in this sphere. Further, while the trade unions should retain their power to secure the fulfilment of the just and fair demands of their members, they should equally remember that trade unionists are members of the community and that their rights are conditioned by the rights of others.

These ideas are largely reflected in the contributions to the *Political Quarterly*, the most important of which are those which address themselves to the practical problems of the ways in which the trade union organization can be adapted to enable the unions to meet their new responsibilities and to throw up leaders capable of displaying the economic statesmanship of the highest order that is now demanded on so broad a front. Mr. B. C. Roberts, for example, points out how much depends, in a democracy like that of Britain, on the willingness of the trade unions and the employers' organizations to face the issues that the Welfare State has posed. The whole future of the Welfare State depends on the ability to overcome the inflationary spiral which now afflicts the economy by increasing the volume of goods and services or by reducing purchasing power; and there is urgent need to change industrial wage structures in the light of technological developments and in the interest of obtaining higher rates of production. Whether the existing system of collective bargaining is capable of achieving the changes required may be doubted, and Mr. Roberts suggests that possibly a more radical approach may be required, such as agreement by the unions to a less centralized system for determining wage-rates. Again, he points out that technical developments in industry, the growth in complexity of trade union functions and the increase in size of the unions have placed increased responsibilities on trade union leaders, whose task is rapidly becoming a professional occupation, demanding a high degree of skill such as can only be obtained by experience and training. While, however, the selection of trade union officials, their tenure of office, remuneration and opportunities for promotion have become, at least in the large organizations, matters of crucial importance, many trade unionists are still reluctant to examine the implications of these questions. The fear of bureaucratic control is justifiable, and it is clear that there is often a lack of understanding between headquarters and the local branches and rank and file of a union, while the national prestige of the Trade Union Congress is not matched by the power of its General Council, which cannot compel an affiliated organization to follow the policies it wishes to see adopted.

Here again it is a question of influence rather than power, in which the character and personality as well as the administrative capacity of the trade union official are all-important. Increasingly he requires exactly those qualities which, as the Acton Society Trust's recent inquiry has shown, industry is more and more finding in those who have entered from the university or grammar school, rather than among those who have risen from the factory floor to management status.

This tendency is an inevitable consequence of the broadening of educational opportunity, and the present distrust of the college-trained trade unionist and feeling against an educated *élite* must disappear in the unions, as they have largely done in industry, if the unions are to secure the talent they need to render their members and the community the service now required of them.

To this problem Mr. H. A. Turner's article on trade union organization and especially Mr. J. A. Mack's article on trade union leadership are devoted, though particular aspects of it also appear in those in which Mr. Clegg discusses the problem of strikes and Mr. Guy Revitt the structure of collective bargaining. Mr. Turner is concerned with questions of size, and touches on those difficult demarcation issues which automation is likely to accentuate. He indicates the need for regrouping and for decentralization as unions and amalgamations grow in size; but it is equally clear that any such measures make large demands on leadership, both at the national and at the regional or local level. It is brought out even more clearly by Mr. Mack, who, moreover, points out that the present confusion in the British trade union movement is derived directly from the failure of union leadership to exercise the responsibilities which are a condition of the proper use of the growing power of the unions, at least on the theory which has sustained the development of the movement for the past thirty years.

Mr. Mack remarks that the leaders are for the most part singularly unaware of the disadvantages under which they labour. While on the whole the unions get the best men available, he quotes Mr. Roberts's verdict, in "Trade Union Government and Administration in Great Britain", that the work of the union official produces tough, self-reliant, pragmatic individuals, men of courage and determination, who better than most know how to take a decision and stand by it. Their self-confidence makes them determined advocates and excellent negotiators, but contrasts sharply with the more sophisticated approach of the politician to problems, and accounts for the contempt they sometimes display to those who have been trained in a more intellectual school. It also accounts for a disposition to let things run, to solve their problems of organization as they arise and to resist any attempt at a major reconstruction of the relations within the individual unions and between unions.

These practical problems of reorganization, however, are becoming more pressing. The fundamental autonomy of the British trade unions in the wider society is not yet even threatened. The formation of the Peoples League for the Defence of Freedom and the activities of the Free Press Society out of which it has grown, as well as the pamphlet, "Spotlight o Trade Unions", recently published by the *Dail Mirror*, are pointers to which the trade unions woul be wise to pay attention. The preservation of th autonomy of the unions is bound up with thei capacity to maintain internal law and order, and t improve the economic and industrial status of thei members without wrecking the national economy.

While most of the leaders may now be prepared t accept the new responsibilities, that will only b reflected in the policy and practice of the unions i so far as there is closer contact and understandin between the leaders and the ordinary member Education is likewise the key to the removal of thos problems which dissensions among the unions create As the *Round Table* emphasized last December, th leaders must increasingly address themselves to th education of members in the facts of modern life.

To a limited extent some of this educational work the importance of which has become even mor apparent in the recent issues raised by automation could be done outside of the unions. It is only likel to be fully effective if it is also undertaken fro within, and it is one of the most important of th ways in which trade union leaders can help to dea with the problems which automation involves. I they are to do this effectively, however, and assis the unions to make the contribution to the increas of productivity that they alone can give, it is increasingly important that the unions should dra into their leadership a fair share of the best abilit available.

This means, as has been indicated, that the union must give increasing attention to the recruitmen and education of their officials. If closer contact an understanding between the official and the ordinar member are needed, it is no less essential that ther should be close contact and understanding betwee the official and the managers, Civil servants, Minister and others with whom he is increasingly required t co-operate as well as to negotiate. He must be abl to meet them on level terms, and he cannot do s unless he has the scientific and technical knowledg which are demanded in industrial and economi decisions to-day.

Here, then, the question of the function of th trade unions to-day, and their reorganization to mak their full contribution to the welfare of their member and of the community as a whole, is linked up wit the expansion of technical and technological educatio and with educational policy as a whole. In so far a technical and technological education is planne to provide industry with the leaders it needs, it mus provide leadership for the unions as well as executive for industry. Moreover, co-operation as well as th provision of such leaders will be increasingly facilitate in the measure in which leaders in the unions an managers and executives in the factories hav received part at least of their training side by side In the range of courses which are offered, whethe by the university, the college of technology or th technical school, there should be opportunities fo the trade unionist leader to acquire the new knowledge and skills he needs, as well as for the tech ologist or the manager to refresh his mind or extend ıe range of his knowledge. Refresher courses and ourses of training for management should be framed rith such possibilities in mind. Similarly, the trade nions must increasingly seek to attract into their ervice some of the ablest minds which the univerities and other institutions can put at their disposal.

It is with such issues as these that the Government hould be showing concern. There has as yet been ttle sign that it has a concerted policy, or that it is repared to take the measures that will be required o win support for an adequate policy of technical ducation, including education for management as ell as preparation of the community for educational hange. It is a Government responsibility to see hat the educational policy of Britain provides ffective safeguards against the ignorance and rejudice which are the most dangerous saboteurs of evelopment and industrial efficiency and prosperity. 'o dispel misconceptions, to establish confidence and o promote adaptability are the first objectives to hich the Government should now be directing its ducational and its economic and welfare policies. here is much to be done ; but the Prime Minister's tatement on June 5 on economic policy and autoation gave little hint that the Government is aware f the needs.

PLASTIC BEHAVIOUR AND DESIGN OF STEEL-FRAME BUILDINGS

he Steel Skeleton
y Prof. J. F. Baker, M. R. Horne and J. Heyman.
ol. 2 : Plastic Behaviour and Design. Pp. x+408.
ambridge : At the University Press, 1956.) 63*s*. net.

DESPITE the fact that the word 'design' appears in the sub-title of this volume, the steelwork esigner might, at first glance, imagine that there is ttle here for him. This, however, would be an roneous impression, for it has never been the ıstom of Prof. J. F. Baker's team to consider an egant theory as an end in itself. Theory and design re complementary and, in this book, their interlation has been taken for granted—so much so that nportant rules of design are in one instance buried a sub-section. The designer certainly will find lequate guidance in designing steelwork by the lastic method ; but he must be willing to relate ıeory to design, and not expect to find routine rocedures handed to him ready-made.

This volume brings the story of Vol. 1 (see *Nature*, 74, 1026 ; 1954) up to the present day. The Bristol ıd Cambridge researches are fully described ; but any structural engineers, alive to recent developents, must already know the story, as it has ppeared over the years in various technical journals. is an instructive tale to those who have yet to ad it ; but most will turn with a sense of satisfaction Chapters 7 and 8, where fundamental theorems and eneral methods of analysis, respectively, are disussed. Here are the roots of the matter.

The latest developments of plastic design are conidered in the chapters on 'shakedown' and on inimum-weight design. 'Shakedown' refers to colpse under live and dead loads which are independently variable, and the true economy of design is discussed in the second of these chapters. Although it was possible, in the early days, to check plastic theory for shed-type frames by full-scale tests to destruction, it is clearly out of the question to attempt the same procedure with multi-story frames. The behaviour of beams and stanchions in such structures can be predicted only from separate small-scale tests and by logical deduction from the results so obtained.

The 'question marks' or points which are still debatable are, therefore, mostly related to the behaviour of stanchions, and, in the book, a careful survey is made, in three chapters, of all the relevant experimental and theoretical data. The forty-five different types of loading to which a continuous stanchion might be subjected are examined, and nine of the most likely more closely studied. Even this simplification leaves a very wide and complex field in which work remains to be done. Perhaps the other 'question mark'—that of the behaviour of joints—might have had more mention, but knowledge on this point is scarcely yet at the text-book stage.

Few people during the Second World War knew, as they lay in their Anderson table-shelters, that they were taking part in a test of the principles of ductility and continuity, as applied to structural design. Chapter 17 describes how from the early success of these shelters, which were the first practical structures designed by the plastic theory, grew the two hundred buildings that have proved the effectiveness of the method. It was the frame of a cinema in Bristol which raised the early queries in the minds of Prof. Baker and his colleagues, and it is perhaps fitting that one of the first multi-story frames designed by the new method should be erected in London for the firm of Technicolor, Ltd.

We are still in the early stages of this new development. Progress is likely to be slow if steel designers and fabricators remain too conservative. Visiting American architects admired the slender unity of Hunstanton Secondary School—the first multi-story frame by the plastic method. We should remember that the advance described in this volume is a British development : British architects and structural engineers should be the first to use its advantages. Certainly to the architect the plastic method opens wide opportunities for new structural shapes in steel, and, even if he cannot follow the mathematics, he will find the chapters on load factor and on application and design of real professional value. To the structural engineer this book is of vital importance. He neglects it at his peril unless he is close to retirement. This is the stuff of the future.

W. FISHER CASSIE

W. A. LANE: A GUY'S SURGEON

Sir William Arbuthnot Lane, Bt.
An Enquiry into the Mind and Influence of a Surgeon.
By T. B. Layton. Pp. viii + 128 + 8 plates. (Edinburgh and London : E. and S. Livingstone, Ltd., 1956.) 21*s*. net.

THIS is a remarkable little book which will be of interest to the large number of surgeons of this generation to whom Lane is known only because his name is attached to certain beautifully designed instruments, and who must therefore wish to know more of the man and his work. The book is dedicated to all Lane house-surgeons; but it is bound to be welcomed by all old Guy's men who, though they may not have served him as housemen, may have dressed for him or otherwise come under his influence in their student days. It will also be read with care by those who, having listened to Lane's disciples, have been puzzled by a certain reserve or qualification in their tributes to his memory. “He was such a good technician that he was able to get away with methods in which others couldn't follow him, and that's why he was so criticized”—a remark of this nature calls for an explanation, and Mr. T. B. Layton's inquiry is most helpful in elucidating the mystery which has long surrounded Lane's work and even his reputation.

Lane's father was an army surgeon, and his childhood was spent in many parts of the world as the young family followed the regiment on foreign service. It is clear that from his earliest years Willie had to take responsibility and fend for himself; though he grew up rather a shy young man, he must have learned independence and self-confidence from his early experiences. As a student at Guy's Hospital he made few friends, partly perhaps because he never had much money to spare for entertainment and recreation. There must have been some such explanation for his rather isolated existence, because later in life he took great delight in entertaining large parties at home, and was one of the first surgeons in London to welcome visitors to his operation theatre.

He entered surgery through the dissecting room, where he devoted special attention to the structure of bone and the mechanics of joints. He was particularly interested in anatomical changes in spinal joints which resulted from occupational stress; and his study of the handicap which a fracture might inflict upon a working man made him severely critical of the orthodox methods of treatment and provided the incentive to improve the results. This led to his outstanding work on the treatment of fractures by open operation and internal splinting.

As a technician he was supreme, and realizing the harm which antiseptics could do in a wound, he introduced his aseptic methods, using long sterile instruments and never touching anything which went into the wound. Mr. Layton's thoughtful and thorough inquiry into the reasons why Lane adopted this technique has not produced a very satisfactory answer. It is clear that “he did not know much if anything about bacteriology”, and this must account for his persistent inability to distinguish between the risks of operating upon open as distinct from closed fractures. We know that he refused to learn from the past; but it is a shock to read that he was unable to learn from his own experience. His contemporaries must have recognized this failing, and their severe criticism of his practice of operating on every closed fracture is therefore readily understandable since it must have appeared to them to be just another error of judgment.

His interest in fractures arose out of sympathy with the working man, and his interest in the colon arose “out of sympathy with a particularly sad type of female patient whose chief complaint was pain in the lower part of the trunk”. Lane's interest in physiology was “relatively small”, but he was an evolutionist with a great interest in “vestiges” and conceived the idea that the whole large intestine was a “vestige”. At any rate it could be harmless only if it was empty, for its contents made people “toxic”, and it was on this assumption that he based his advocacy of colectomy. Sir Arthur Keith summed up his lack of scientific background in the remark: “I should hardly call him a clever man. He was emotional and highly strung; a man of feeling”.

Lane was distinguished not only for his technical skill but also for his exemplary behaviour toward his assistants, including his nurses who were devoted to him, and to his patients. He was always self-controlled, dignified and honourable. He set very high standards for himself and for his team; bu although he did not overlook faults in others, neithe did he try to shelter himself behind his subordinate when things went wrong. Many of those around him realized that they were being “mesmerized”, but they could forgive him his faults because, as Sir Coope Perry said of him, “with it all he was such gentleman”.

J. Paterson Ross

DIELECTRICS

Dielectrics and Waves

By Prof. Arthur R. von Hippel. Pp. xii+284. (New York: John Wiley and Sons, Inc.; London Chapman and Hall, Ltd., 1954.) 128*s*. net.

Dielectric Materials and Applications

Edited by Prof. Arthur R. von Hippel. (Technology Press Books in Science and Engineering.) Pp. xii+438. (Cambridge, Mass.: Technology Press of the Massachusetts Institute of Technology; New York John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1954.) 140*s*. net.

PROF. A. R. VON HIPPEL is very strongly against the view that as science advances the scientists have to become more and more specialized He is convinced that exactly the opposite is the case as our knowledge grows, old boundaries vanish and no scientist can afford to ignore what happens in fields outside his own. Dielectrics is a particularly suitable subject to demonstrate the interdependence of the various branches of science as it is of interest to so many people—to the physicist, chemist and electrical engineer, to the pure and applied research worker and the development engineer alike. To make these people feel at home with each other is the principal aim of these two books.

The first book, “Dielectrics and Waves”, was written by von Hippel alone, and deals with the fundamental aspects of the interaction of dielectrics with electromagnetic waves. The first part of this volume gives an account of the macroscopic theory of polarization, magnetization and dielectric loss while the second part develops the atomic theory o dielectrics, in particular the foundation of wave mechanics, the structure and energy-levels of the atoms and the spectra of atoms and gaseous molecules.

In contrast to atoms and gaseous molecules liquids and solids are treated in rough outline only a few selected topics, such as ferro-electricity and piezo-electricity, are discussed more thoroughly

The presentation is very good. Although the author often goes into considerable detail, in particular where atoms and molecules are concerned and does not attempt to hide all the difficulties, the book nevertheless makes pleasant reading. There are a few passages likely to lead to misunderstanding There is, for example, a statement at the beginning of Chapter 24, from which those not acquainted with the subject are bound to conclude that in a consider-ble number of molecules the atoms are held together ainly by Van der Waals forces. The reader may lso come to false conclusions concerning the internal eld, as the Clausius–Mosotti equation is given far oo much prominence. Although it is pointed out at there are some objections to this equation and e alternative Onsager formula is also discussed, evertheless many readers may get the impression at the validity of the Clausius–Mosotti formula is uch wider than it actually is. This idea has led to any mistakes in the past and it should be disouraged.

Apart from minor criticisms of this type, a great ariety of readers will find the book instructive and seful. There is every reason for hoping that the uthor will meet with considerable success in his ain aim, namely, in helping the physicist, chemist nd electrical engineer to understand one another nd in making them interested in each other's work.

The second book, "Dielectric Materials and Appliations", is based on papers presented at a symposium. t starts with a theoretical introduction by von ippel which, on the whole, is a very much shortened ersion of the contents of the first book. The rest f the second book, consisting of papers by twentyne different contributors, deals with a great variety f practical aspects connected with dielectrics, ncluding measuring techniques, dielectric materials sed in all sorts of electrical equipment and devices, om power cables to memory devices, and there are so three papers on the dielectric requirements of e American army, navy and air force. The book so contains very extensive tables on dielectric data. nybody who wants to acquaint himself with the roblems arising in the practical applications of ielectrics will find this book an excellent introuction to the subject.

B. SZIGETI

APPLIED SOLAR ENERGY

oceedings of the World Symposium on Applied Solar Energy

hoenix, Arizona, November 1–5, 1955. (Sponsored The Association for Applied Solar Energy, Stanrd Research Institute, University of Arizona.) Pp. 4. (Melno Park, Calif.: Stanford Research Initute, 1956. Copies available from the Association r Applied Solar Energy, Phoenix.) 5 dollars.

THE scope of this first World Symposium on Applied Solar Energy has already been described some detail in *Nature* (177, 110; 1956), and in viewing the proceedings only brief mention will be ade of the contents. The volume consists of twentyur main papers delivered at the Phoenix Conference, d includes the opening remarks by Lewis W. ouglas, the welcoming luncheon address by Sir lward Bullard, and the banquet address by John y Hopkins, "Towards a New Heaven and a New rth". There is also a record of the panel discussions solar house heating, architectural problems, and e future of applied solar energy. A description of e Solar Engineering Exhibition is included.

The general extent of applied solar energy research now well known and includes low-grade heat plications such as water and house heating, cooking, ter distillation, high-temperature solar furnaces, chanical and electrical power, refrigeration, cheml energy conversion and artificial cultivation of algae. All these applications are described in considerable detail by experts who have personally conducted research in the particular field concerned, and together the papers give a comprehensive picture of the present position. It is perhaps the future possibilities that will most interest the general reader. Economics is the controlling factor, and careful design is necessary to reduce the equipment to the most simple form. The introduction of new materials and methods of construction will greatly reduce the capital cost of equipment. Applications are mostly limited to regions of high solar radiation, and in such localities solar energy could be integrated with existing forms of energy supply. The greatest scope lies in countries which are located in lat. 20°–40° N. and S., and which are at present industrially undeveloped. Solar energy must in the future fulfil an essential need in such areas as development and research proceed.

The promoters of the Symposium are to be congratulated on producing in a relatively short time a volume which is very well printed and clearly illustrated, and which comprises so much interesting information on the subject.

H. HEYWOOD

NUCLEAR ENGINEERING

Principles of Nuclear Reactor Engineering

By Samuel Glasstone. Pp. ix+861. (London: Macmillan and Co., Ltd., 1956.) 60*s*. net.

THE earlier work, "The Elements of Nuclear Reactor Theory", in which Dr. S. Glasstone collaborated with Dr. M. K. Edlund, has become a standard text-book for the rapidly growing number of nuclear reactor engineers. To say that my immediate reaction to this newer work by Dr. Glasstone was one of disappointment is not to belittle the book, which is the most complete of its kind yet published. It is aimed particularly at "the practising engineer who wishes to know something of the impact of nuclear energy on his professional activities" and "students in engineering schools at the senior or first year graduate levels". The difficulties in catering for the two classes of reader in the same book are apparent in the text.

After a 57-page summary of the scope of the book, three chapters are devoted to basic nuclear physics and reactor theory. Thanks to a more concise treatment of slowing-down theory, and to the omission of much of a purely mathematical nature, the contents of the earlier book have been compressed with perhaps some gain in lucidity. Enough theoretical and experimental information is now available on fast reactor theory to warrant a much fuller discussion than is given. Wisely the terms 'geometrical buckling' and 'material buckling' have been omitted, as has also (perhaps unwisely) the 'track length' explanation of the misnomer 'neutron flux'. There is an excellent discussion of the effects of variation of lattice parameter.

The chapters on instrumentation and control are very clearly written, though in a book of this scope perhaps the automatic control of reactor systems should be accorded greater importance. Actinide chemistry is dealt with at some length in the chapter on fuel processing and is followed by a discussion of the principles of chemical separation. The build-up of higher isotopes in a reactor justifies a much more comprehensive treatment than it receives here. In the chapter on materials, the extraction and fabrication of uranium and thorium are dealt with briefly, and a few lines are devoted to alloys of these elements. Reactor materials and the effects of irradiation upon them are concisely described. Two chapters follow on radiation protection and shielding. The important field of the disposal of radioactive waste merits a fuller and more quantitative treatment.

The difficulty of aiming at a wide audience is particularly apparent in the chapter on thermal aspects of nuclear reactor systems. Most of the elementary treatment of heat transfer and fluid flow could well be omitted. The resulting space could profitably be devoted to a fuller treatment of the temperature distribution inside a reactor, the problems arising in matching the reactor to a power cycle, and the thermal aspects of the dynamics of reactor systems. The penultimate chapter deals in a rather tedious manner with design variables, and the book is completed by description of a number of reactors.

Perhaps the major criticism of this book is that, although officially sponsored and published at the time of the Geneva Conference, it is based on pre-Geneva information. No doubt steps will be taken to correct this in later editions. W. MURGATROYD

TREATISE OF ZOOLOGY

Traité de Zoologie

Anatomie, Systématique, Biologie. Tome 17: Mammifères. Les Ordres: Anatomie, Ethologie, Systématique. Publié sous la direction de Pierre-P. Grassé. Fascicule 1: Pp. viii+1,170. Fascicule 2: Pp. vi+1,171–2,300. (Paris: Masson et Cie., 1955.) Paper bound, 11,000 francs; cloth bound, 11,800 francs each.

IT is a welcome task to review another volume of the "Traité de Zoologie" edited by Pierre-P. Grassé; and an imposing volume it is, being composed of two fascicles each larger than some of the preceding volumes—it is perhaps unavoidable that the price is also imposing. This is one of the two volumes devoted to mammals; the first, which has not yet appeared, will deal with the anatomy and reproduction of the mammals in general. The present volume is devoted to the systematics, with quite a fair amount of the relevant special anatomy of skeleton, brain, viscera and urinogenital system, and the biology in quite a wide sense.

Throughout the systematic arrangement, adequate weight is given to the fossil forms and to discussions of their relationships with living groups. In this connexion the sections on fossil Proboscidians, on fossil Perissodactyla, on fossil Simioidea and fossil man appear particularly useful. The classification of the Eutherian mammals owes a good deal to that of Simpson (1945) and of Ellerman and Morrison-Scott (1951), but with modifications; for example, the carnivores are subdivided into two orders, the Fissipedia (terrestrial forms) and the Pinnipedia (amphibious forms). There appears to be some confusion in respect to the systematic position of *Tupaia*, a subject that has been much discussed. On p. 1,653 it states that G. G. Simpson (1945) recognizes six superfamilies in the Insectivora, of which the sixth is the Tupaioidea. In Simpson's well-known principles of classification (1945), however, he has eight superfamilies in the Insectivores—three fossil and five recent—and the Tupaioidea are not included. On the other hand, as is stated clearly and correctly o p. 1,646 and again on p. 1,855, Simpson places th Tupaiidae in the sub-order Prosimii of the Primate (a procedure with which the present work does no agree). In checking the references to *Tupaia* in th index, two pages are given, 1,722 and 1,969, on neithe of which is this genus mentioned. Following genera usage, *Oryctolagus* is separated from *Lepus* an *Panthera* from *Felis*; but, as a rule, as is advisabl in a book of this nature, the specialist splitting o genera has not been widely followed, although th separation may be indicated by the newer name i brackets. In some groups, for example, the Rodentia trinominal terminology is often employed.

As in former volumes, the illustrations form a important and valuable feature, and it is claimed tha nearly three-quarters of the genera are illustrated There are more than two thousand text-figures about two hundred half-tones of photographs, thre hundred half-tones of drawings, mostly wash, 1,58 line drawings, six reinforced by colour, and fou full-page coloured plates. As might be expected wit such a large number of illustrations, they are not al of the same quality, although the majority ar excellent. The technique of the line-drawings fo Figs. 349 and 380, for example, is not nearly so goo as the general run and in particular such as Figs. 5 and 1,151, among many others. Fig. 1,711, a line drawing reinforced with colour, is another excellen one. The half-tone of a photograph in Fig. 1,191 i quite poor. Most of the half-tone illustrations o drawings are good; but some, like Figs. 766 and 1,187 are outstanding. This question of the illustrations ha been dealt with at some length because they have bee stressed in the advertisements, and it costs no mor to reproduce a good illustration than a bad one. Fig 278 is upside down, and the legend of Fig. 1,98 states that it represents "mains droites" whereas the are left hands. In most of the figures of fossil form the scale is given so that an idea of the size of th animal can be obtained; but it is a decided disadvantage that this is rarely done in the case of th living creature, so that, unless the reader is familia with the genus, only a vague idea of the size is conveyed. Indeed, when more than one animal is depicte on the same page, no idea of the relative size can b obtained.

As in preceding volumes, experts have contribute the sections dealing with their own fields of study: i all, there are fourteen, including the editor, and the have been drawn from as far afield as Brussels, Daka and Lisbon. This not only means authoritativ treatment but also ensures that each part is up t date; this is shown by the inclusion of severa references to papers published in 1955, the same yea as the volume itself, and in the addenda is a brie account of ultrasonics and echo-location from th proofs of a paper that had not then appeared. Afte the treatment of each order, there is a valuable selected bibliography.

Here, then, is a book that fills a noticeable gap i general zoological literature. Perhaps the neares work, in English, with which it can be compared i Beddard's "Mammalia" in the Cambridge Natura History, which was published in 1909. The "Traité" however, is not only wider in scope but naturally deal with a much larger number of animals and bring home clearly the changes in outlook and knowledg that have occurred in the past half-century. There i no doubt that it will remain an indispensable work c reference for many years. C. H. O'DONOGHUE

Petrographic Mineralogy

By Dr. Ernest E. Wahlstrom. Pp. vii+408. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 62s. net.

PROF. E. E. WAHLSTROM'S "Petrographic Mineralogy" is intended to bridge the gap which exists between text-books that explain the theory of the polarizing microscope and other instruments used n a petrographic laboratory, and those that describe the classification and properties of rocks and minerals.

The subjects dealt with in the first five chapters are the various petrographic methods and techniques that a student should know how to use, and they range from notes about the correct method of collecting and sampling rocks to detailed instructions for the use of the universal stage. The various optical, physical and chemical methods commonly used in the identification of minerals (excepting the goniometer) are all referred to, the emphasis being on identification in thin slice. The next two chapters describe the rock-forming minerals under two headings—silicates and non-silicates. Chapter 8 contains tables for the identification of minerals. The last three chapters deal with the composition, properties and classification of gneous, sedimentary and metamorphic rocks. All this matter is comprised within a book of rather less than four hundred pages, so that there is necessarily much compression; but the large number of explanatory line-diagrams and of photographic reproductions of rock-sections goes far towards compensation for this brevity.

This book is obviously designed to be placed in the hands of students after a preliminary term or two of instruction in the theory and use of the petrographic microscope. Such students, armed with this text-book, might then be expected to make good progress with a minimum of supervision—a great advantage, no doubt, in large classes. Used inteligently, and with aid of the references to further ources of information placed at the end of each chapter, it should fulfil the author's intention successfully.

Soil Zoology

Proceedings of the University of Nottingham Second Easter School in Agricultural Science, 1955. Edited by D. Keith McE. Kevan. Pp. xiv+512+16 plates. London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1955.) 55s.

THE study of the fauna of the soil has lagged far behind the study of its chemical and physical properties. The aim of the organizers of the second Easter school in agricultural science, held in Nottingham last year, was to direct attention to this deficiency. Those soil workers who had in the past neglected the fauna because they were unfamiliar with the methods of the zoologist had an opportunity at Nottingham to obtain instruction on the principles of animal identification and on various techniques, as well as hearing more specialized papers describing esearch on the soil fauna. This information is now made more widely available by the publication of he proceedings, edited by D. K. McE. Kevan.

There are contributions by workers from the Continent of Europe, including Kuhnelt, Kubiena, Fischler, Haarløv, Overgaard Nielsen and Brauns, s well as workers in Britain. The contents are ivided into two parts. Part 1, which occupies two-hirds of the volume, contains twenty-six papers on dentification, general biology, ecology and applied aspects. Part 2 contains twenty-five papers describing methods of soil sampling, culturing, preserving and mounting animals, soil sectioning after impregnation with agar, and certain physiological techniques.

In an appendix, Mr. Kevan has included a useful key to the major groups of soil and litter animals. This key occupies thirty-six pages of small type, and contains numerous line diagrams. There are a good general index, an author index, and indexes to the genera of animals and plants mentioned in the text.

L. H. FINLAYSON

Introduction to Physical Geology

By Prof. Chester R. Longwell and Prof. Richard Foster Flint. Pp. x+432. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 40s. net.

IT might be expected that a book from the pens of two such experienced geologists and teachers as Profs. C. R. Longwell and R. F. Flint would be outstanding in quality, and this one does not disappoint. It develops the basic principles of the science by means of a careful examination of field evidence and also with the aid of a very large number of illustrations, including several instructive air photographs, many of which will be new to British readers. An important feature of the book is the care which has been taken to make these illustrations intelligible to the inexperienced readers for whom it is intended.

An unusual feature is the inclusion of brief references to the history of the subject, indicating to thoughtful readers that many of the conclusions which he tends to accept as axiomatic were only arrived at after much hard thought. The authors quote, for example, Shakespeare's lucid exposition of the cause of earthquakes, which expresses, not a playwright's fancy but a view held in his time and for centuries earlier.

The book embodies a wealth of experience, principally that of its authors, but also that of many others whom they consulted while writing it. It will prove a very useful addition to the departmental libraries in universities, and in schools in which geology is taught.

Discoveries and Inventions of the 20th Century

By J. G. Crowther. Fourth edition, entirely revised and rewritten. Pp. xvii+432+64 plates. (London: Routledge and Kegan Paul, Ltd., 1955.) 30s. net.

ALTHOUGH this fourth edition has been entirely revised and rewritten, Mr. J. G. Crowther has retained the general form of the third edition. Some chapter headings have been changed and much new material incorporated, covering inventions and developments of the past twenty-five years. Whether this is now quite appropriate is a matter of opinion; but the treatment of plastics appears to have been prejudiced by the arrangement, and in this edition is quite inadequate. Something should have been included on the advances in medicinals during this period, if only because of the far-reaching effects of the control of malaria, trypanosomiasis and other killing diseases.

Criticism of omissions, however, is invidious and, apart from these two features, the book gives a comprehensive and readable picture of the discoveries and inventions of the past fifty years. Of minor slips, attribution of the invention of chromatography solely to Tswett instead of to Runge and others may be mentioned.

R. B.

THE GEORGE R. AGASSIZ RADIO TELESCOPE OF HARVARD OBSERVATORY

By Prof. BART J. BOK

Harvard College Observatory

ON April 28, two hundred staff members and guests gathered at Harvard Observatory's Agassiz Station in the town of Harvard, Massachusetts, to assist in the dedication of the 60-ft. radio telescope that carries the name of Harvard Observatory's long-time benefactor, the late George R. Agassiz (1862–1951). It was fitting that Dr. Alan T. Waterman, director of the National Science Foundation, should have officiated at the dedication, since the Foundation, with further assistance from friends of the Agassiz Station and from the Research Corporation of New York, had provided the funds for the construction of the new radio telescope.

The Antenna and its Mounting

The 60-ft. instrument was built by D. S. Kennedy and Co., of Cohasset, Mass. Its antenna is a paraboloid of expanded aluminium wire-mesh, each square of the mesh measuring $\frac{3}{8}$ in. on a side; tests by the Kennedy engineers indicate that the antenna surface is a true paraboloid to within $\frac{1}{8}$ in. A horn-feed at the focus collects the radiation received by the antenna.

The mounting of the antenna is of equatorial design and the telescope is motor-driven. Preliminary purely mechanical adjustment produced a position for the polar axis of the instrument to within a fraction of a degree of the true pole, and final adjustment by the usual optical techniques has now been completed. The setting and following accuracy of the instrument required by contract is of the order of ten minutes of arc; the manufacturers have provided for even greater precision of setting and following, with maximum uncertainties in either co-ordinate apparently no greater than two or three minutes of arc. The instrument will be used initially for research at the wave-length of the neutral hydrogen line at 21 cm.; at this wave-length the angular resolution of the Agassiz radio telescope is of the order of seven-tenths of a degree, so that the setting and following accuracy that is attainable with the instrument are more than sufficient for research on discrete radio sources.

One feature of the mounting that is especially worth mentioning is the polar axis of the instrument, which is in essence a single roller bearing with a diameter of 7 ft. The shortness of the polar axis permits the pointing of the antenna to any direction above the horizon.

The Electronic Equipment

The electronic equipment was constructed by the Ewen-Knight Corporation, of Needham, Mass., and it has been designed primarily for research dealing with the radio radiation of wave-length 21 cm. emitted by neutral, atomic hydrogen in interstellar space. The 21-cm. lines received on the Earth from most directions in the sky are widened considerably in frequency caused by the rotation of our galaxy. At the frequency of 1,420 Mc./sec., corresponding to the wave-length of 21 cm., the line-widths produced by galactic rotation alone amount often to as much
2 Mc./sec. We note here that a radial velocity shi
of 1 km./sec. at a frequency of 1,420 Mc./sec. amoun
to a frequency shift of very nearly 5 kc./sec. Rando
turbulent velocities of the hydrogen clouds of o
galaxy also contribute to the observed shapes of t
hydrogen-line profiles. In all of the research to da
at the Agassiz Station, special emphasis has bee
placed upon high resolution in frequency. For t
research of the past three years with the 24-f
steerable paraboloid, we have used apparatus with
frequency band-width of 15 kc./sec., equivalent to
resolution of 3 km./sec. in radial velocity. The ne
equipment is designed for primary operation with
band-width in frequency of 5 kc./sec., or an equ
valent resolution of 1 km./sec., in radial velocit
The new electronic equipment has been designed b
Harold I. Ewen, who, with the present writer, h
from the start been the co-director of the Agass
Station Radio Astronomy Project. The instrume
has been described as follows by its designer:

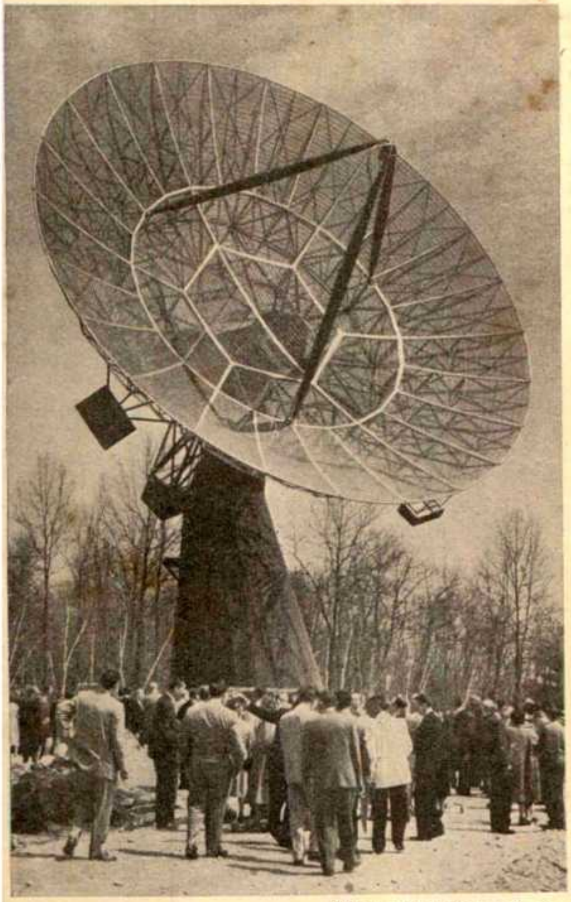
The receiver is a microwave double-conversio
superheterodyne comparison radiometer. Compariso
is achieved by 400 c./sec. switching of the first loc
oscillator between two frequencies spaced 2 Mc./se
apart. As a result, the receiver compares 'signal
band' information to a signal-free 'noise-band' at
rate more rapid than normal gain fluctuations. B
this means the effect of receiver-gain fluctuations
considerably reduced at the receiver output.

The Model 1044 radiometer incorporates som
rather fundamental changes in the normal design f
equipments of this type. A significant departu
from the more conventional approach is the doubl
bank 20-channel comb filter at the second conversio
frequency.

The twenty filters each have a band-width
5 kc./sec. and are spaced 100 kc./sec. apart to cove
a complete 2 Mc./sec. band. Their effect is the sam
as twenty receivers operating in parallel, each tune
100 kc./sec. from the one on either side.

For a particular tuned frequency, all channe
operate simultaneously and store their individu
information in integration networks. The chargi
time or integration time of these twenty networks
110 sec. At the end of the charging time, t
integrated information is 'read out' from ea
channel, in sequence, by an analogue to digit
computer, and recorded by an electric typewriter
the first row of twenty numbers in a 2 Mc./se
scanning sequence. The second local oscillator is the
'step-tuned' 5 kc./sec., which effectively moves eac
of the twenty channels 5 kc./sec. higher in inform
tion-response frequency. The integration sequence
repeated and recorded by the typewriter as t
second row of twenty numbers in the 2 Mc./sec. sca
This sequence is repeated twenty times until t
typewriter output consists of twenty rows of numbe
arranged in twenty columns.

The first column of twenty numbers represents t
first 100 kc./sec. of the desired 2 Mc./sec. of inform
tion. The second column covers the range 100 kc./se



[Photograph by Robert E. Cox

Fig. 1. The 60-ft. George R. Agassiz Radio Telescope, Harvard Observatory

to 200 kc./sec., etc. Each of the four hundred numbers typed represents the average hydrogen temperature above background as measured in an individual 5 kc./sec. frequency-band. The entire 2 Mc./sec. scan is accomplished in 40 min., as compared to single-channel operation requiring 13 hr. 20 min.

Programme of Research and Training

From its initiation, the Agassiz Station project in radio astronomy has had the dual aim of training graduate students and of advancing research in the field. The completion and putting into operation of the 60-ft. radio telescope should serve to strengthen both parts of the programme, since the project will in all likelihood remain one operated primarily for and by graduate students in radio astronomy. Such a policy is in line with that of the National Science Foundation, the organization that has thus far borne a little more than half the expense of operating the project. However, the planning of research and the granting of permission for guest observers to use the equipment will now become more flexible, since we shall have available both the 24-ft. and the 60-ft. radio telescopes. The future may, therefore, well see a considerable extension of the programme outlined below.

The Harvard programme to date has been primarily concerned with astrophysical studies of 21-cm. radiation relating to interstellar neutral, atomic hydrogen. One of the first results with the 24-ft. radio telescope was the discovery by Lilley[1] of excessive concentration of neutral atomic hydrogen in the Taurus Complex of dark nebulosity, which led to the conclusion that the average ratio of densities of gas to dust in the large dust complexes is about 100 : 1. This ratio appears now to be constant as we proceed to the smaller dust units; but obviously the search for and study of small-scale concentrations of neutral atomic hydrogen associated with dark nebulæ presents an important problem for the new instrument with its high angular resolution.

Lawrence[2] and Heeschen and Drake[3], working with the same instrument, have already done some interesting work relating to the fine structure of the interstellar hydrogen medium. Lawrence has studied certain regions near stars for which Münch, at Mount Wilson and Palomar Observatories, had found optical evidence for multiple interstellar lines. Two interesting cases of coincidence between optical and 21-cm. wave-length radial velocities have already been found; the availability of the 60-ft. radio telescope with its high angular resolution and the improved resolution in frequency of the electronic apparatus holds great promise for future research in this field. Heeschen and Drake studied the 21-cm. wave-length radiation in the Pleiades cluster, and here they found evidence for a double-peaked 21-cm. profile, with one component coinciding in radial velocity almost precisely with that of the Pleiades cluster of stars, the other with that of the optical interstellar absorption lines. The completion of the 60-ft. radio telescope makes it profitable to examine the 21-cm. wave-length radiation from many clusters of stars, from associations and aggregates, and from certain diffuse nebulæ and the regions surrounding them. The researches by Menon[4] of the Orion Complex illustrate how much we can learn from a detailed survey on a wave-length of 21 cm. of a section rich in *O* and *B* stars, emission and reflexion nebulosity and cosmic dust. Similar work can now be attempted for smaller sections of special interest. Among regions of the sky that will be receiving special attention with the new equipment are the clusters and associations *NGC* 2244 and 2264 (Menon) and the region of λ Orionis (Campbell M. Wade).

One of the most important fields of research on the 21-cm. wave-length is the study of the spiral structure of our galaxy—a field in which the Dutch and Australian astronomers have excelled. At the Agassiz Station, we have in this area concentrated on investigating in detail a few sections of special interest, stressing at all times the close interrelation that exists between optical and radio research. To date, the principal effort has been for galactic longitudes $l = 60°$ to $135°$, for which we have some results by Matthews[5] and by Davis (unpublished). These researches reveal an amazing degree of fine structure in the portions of the three major spiral arms that are observed in this section. There are several instances of apparent bifurcation, and it is most striking how certain apparently minor features may be traced over a considerable range of galactic longitude and latitude. Matthews and Davis especially directed attention to the great mass of the neutral atomic hydrogen associated with the Perseus arm as compared to the Orion arm—a surprising result in view of the greater distance of the Perseus arm from the centre of our galaxy. With the new equipment we hope to extend these studies with point-to-point analyses for the detailed structure near positions of critical importance from the radio or optical point of view. In addition to the section $l = 60^\circ$ to 135°, we are concentrating on the region of the Cygnus cloud (Mrs. May Kassim), and in the section $l = 335^\circ$ to $l = 15^\circ$ for which Howard and Heeschen[6] have already reported preliminary results.

The study of the absorption features in the 21-cm. wave-length profiles for regions centred upon discrete radio sources is not practicable with our 24-ft. antenna, but it has already been demonstrated by a brilliant investigation at the Naval Research Laboratory in Washington, D.C., that this is an exceedingly profitable research field for radio telescopes of 50-ft. aperture and greater. We plan initially to concentrate on this type of research with the 60-ft. George R. Agassiz radio telescope. The narrow band-width and accompanying high resolution in frequency of Dr. Ewen's equipment will prove invaluable for studies at 21-cm. wave-length of discrete sources and the regions near them.

At the time of the dedication of the Agassiz radio telescope, Dr. Heeschen announced the discovery of 21-cm. radiation from the direction of the Coma Cluster of galaxies at a distance of approximately 75,000,000 light years from the Sun. The shift in frequency of the 21-cm. wave-length feature indicated a recessional radial velocity for the atomic hydrogen in good agreement with the radial velocity of recession found optically for the galaxies in the Coma Cluster. The dispersion in radial velocity suggested by the radio observations is comparable with, though slightly less than, the value found from the optical evidence. Heeschen's results were obtained with the 24-ft. paraboloid. The 60-ft. telescope will assist in localizing the source or sources of radiation of 21-cm. wave-length in the Coma Cluster of galaxies, and with the new equipment several other clusters of galaxies come within reach.

The results of research with radio telescopes of apertures between 24 and 50 ft. have shown already that the 21-cm. wave-length field is a rich one for future research with radio telescopes of larger aperture, especially when the results of optical and radio studies are brought to bear upon the solution of any given problem. For the present we have limited ourselves largely to research in our own galaxy; but already it is obvious that radio telescopes with apertures of 60 ft. and greater have important contributions to make in the study of 21-cm. wave-length radiation from other galaxies and from intergalactic space.

A 60-ft. radio telescope with a precision paraboloid antenna is a versatile instrument and can be used effectively for studies at wave-lengths other than 21 cm. It would be presumptuous to suggest at this time the uses to which the Agassiz radio telescope may be put in the years to come. There are, however, two areas of research in which the instrument is expected to make some contribution in the not too distant future. One is the study of the continuum near 21 cm. wave-length and possibly at other wave-lengths in the range 10–50 cm. The other is in the search for other line emission or absorption features, notably in an attempt to find evidence for the presence of OH at a wave-length near 18 cm. (frequency approximately 1,667 Mc./sec.).

To describe the future programme of a 60-ft. radio telescope is really a very difficult task. For, as radio astronomy is coming of age, it takes its place—along with photoelectric photometry and spectrography—as one of the basic techniques for the study of the physical universe. A 60-ft. radio paraboloid may in the future have as many roles as have in the past the 60-in. reflectors for optical studies of our Milky Way System and other galaxies.

THE GOUGH ISLAND SCIENTIFIC SURVEY, 1955–56

By M. W. HOLDGATE, R. W. LeMAITRE, M. K. SWALES and N. M. WACE

THE background and personnel of the Gough Island Scientific Survey, which has recently returned to Britain, and the little that was known about Gough Island prior to its visit, have been described in an earlier article[1]. The expedition left England in September 1955 and landed on Tristan da Cunha on October 1. During a six-week stay there, the vegetation, agriculture and bird-life were studied in detail, and some rock specimens and invertebrate animals were collected. Peat samples for subsequent pollen analysis were obtained from a lowland and an upland bog.

On November 13, 1955, a landing was made on Gough Island. This island lies on the central Atlantic ridge, some 230 miles south-south-east from Tristan, the centre of the island being about 40° 17′ S. and 9° 56′ W. It is about eight miles long and four miles wide, and, like Tristan, is more than 1,500 miles distant from the nearest continent.

Within a few minutes of landing, the Expedition's leader, Mr. R. J. H. Chambers, collapsed with a back injury which necessitated his evacuation three days later. He was succeeded by Dr. M. W. Holdgate. A sectional wooden hut was erected near the landing place, as a base, and after paths had been cut through the forest to facilitate access to the high ground, two tented camps were established on the mountains. The exploration of the island was carried out from these camps, and also from Base, using a dinghy. The Tristan islanders, of whom two pairs were at different times employed by the expedition, proved especially skilled at handling a boat, and landings were made on all except the west coast of Gough.

In February 1956, Mr. J. B. Heaney, the organizer and original leader and surveyor of the expedition, joined the party and became joint-leader with Dr. Holdgate. The expedition was relieved by the South

African frigate *Transvaal* on May 13, 1956. The installations were taken over by the South African Weather Bureau, which will continue the meteorological station on Gough until the end of the International Geophysical Year.

Topography and Survey

Mr. J. B. Heaney, assisted by Dr. M. W. Holdgate and other members of the expedition, surveyed the island on a scale of 1/30,000. A triangulation scheme involving twenty-five stations provided a network of fixed points including the main peaks and many coastal features. The baseline, 1,860 ft. in length, was measured on a plateau 2,000 ft. above sea-level in the centre of the island. The latitude and longitude of a trigonometrical station near the hut was determined from position-line observations on sixteen stars. The detailed survey was carried out using a plane table on which rays were plotted to a large number of features. An 80-cm. rangefinder was used for measuring distances, and the vertical angles from a clinometer enabled these to be corrected to the horizontal in the field. A dense control of spot heights was established, and contours at an interval of 250 ft. were interpolated.

The centre of the island proved to be an undulating plateau some 2,000 ft. above the sea. The highest peaks rise 500–1,000 ft. above this (the summit of the island being provisionally fixed at 2,995 ft.). Peat bogs cover the plateau, but in the north there are extensive areas of bare rock. Along the north and east sides, eight deep valleys cut back into the plateau; these are 1–1½ miles long and are separated by narrow, craggy ridges. On the west the plateau slopes more evenly to the top of the sea cliffs, which, though nowhere sheer, are up to 1,500 ft. high. In the south there is a strip of level lowland about half a mile wide, between the mountains and the sea. Most of the island is surrounded by cliffs, and there is only one landing place which gives easy access to the interior.

Meteorology

A meteorological station was established at Base, 20 ft. above sea-level, and operated continuously from November 20, 1955. The instruments were provided by the South African Weather Bureau, which seconded Mr. J. J. van der Merwe to the expedition as meteorologist.

During the five months December–April inclusive, the mean monthly noon temperatures were 15·2, 14·6, 15·4, 13·9 and 13·7° C., respectively. The highest maximum temperature during the period was 23·7° C. (on February 17) and the lowest minimum 5·5° C. (January 25). The rainfall totals for the five months were 197·7 mm., 304·5 mm., 152·2 mm., 101·0 mm. and 261·9 mm., while the mean daily sunshine figures were 5·4, 5·5, 4·7, 3·2 and 1·8 hr., respectively. The climate was oceanic, and was dominated by a succession of warm and cold front systems.

Orographic cloud was frequent over the island, and standing-wave cloud systems often formed in the lee. Some photographs and notes of these were obtained.

A few tidal readings, on a graduated pole, indicated a mean tide-range of about 3 ft., increasing to 3 ft. 6 in. at springs.

Geology

By R. W. LeMaitre, St. John's College, Cambridge

More than two hundred rock specimens were collected from a large number of localities on the island. These will be worked up in the Department of Mineralogy and Petrology at Cambridge, and it is hoped to publish an account of their petrology in the near future.

In the field it was possible to distinguish four main phases in the structure of the island: (1) an extrusive phase of basalts with minor tuffs, later invaded by dykes; (2) an extrusive phase of trachytes, mainly in the west of the island, preceded by an explosion forming thick local deposits of tuff; (3) another extrusive phase of basalts overlying the two earlier phases; (4) an intrusive phase of trachyte laccoliths and plugs. It is hoped that some of the trachytes will be dated by the radioactive potassium/argon ratio, and that some palæomagnetic work will be possible with the aid of some orientated specimens.

Botany

By N. M. Wace, Department of Botany, The Queen's University, Belfast

No systematic work having been possible during the three previous brief visits of botanists to Gough Island[2–4], collection and description were the first botanical tasks of the expedition. Studies were also made on the dispersal mechanisms and reproductive methods of the vascular plants.

Collections immediately revealed that the number of species is extremely small, the provisional number recognized in the field being thirty-eight angiosperms (of which six are probably human introductions), twenty-five pteridophytes, and about a hundred bryophytes. Freshwater and marine algae, lichens and fungi were also collected. The first set of all the collections will be presented to the British Museum (Natural History).

Studies on the vascular plants emphasized the widespread reliance upon wind as an agent of dispersal and pollination, the almost complete absence of annuals among the native plants, and the general dependence upon vegetative, rather than sexual, reproduction.

Blanket peat covers almost the entire island. Below about 300 m. (1,000 ft.), to the east and south, this supports a dense forest in which a mosaic of communities dominated by *Phylica arborea*, *Blechnum tabulare* and *Histiopteris incisa* are the most important components. At a similar altitudinal range on the western cliff-slopes, tussock-grasses form an almost pure community on dry, stable peat. Above the forest and tussock associations, and up to 450 m. (1,500 ft.), a variety of species, notably *Empetrum rubrum*, *Acaena* spp. and *Apium goughensis*, are the most important dominants in a zone of upland peats. From 450 m. to the highest points in the island (about 900 m.), a zone of thin wet alpine peats dominated by small species of *Agrostis* and *Scirpus*, with numerous bryophytes, covers all but the most exposed rock. Valley bog communities, dominated by *Sphagnum* spp. and other bog bryophytes, occur in all the mountain valleys and on the plateaux above 450 m.

Some descriptive work was also done on the marine algal communities, in which a littoral zonation was very marked despite a mean tide-range of only 0·8 m. (3 ft.). A sub-littoral zone of *Macrocystis* sp.

occurs around much of the east (prevailing lee) side of the island.

Two peat sites were investigated by boring in Tristan and one on Gough Island. Stratigraphical and sampled bores were made in all three sites, and samples also obtained for radiocarbon dating. No definite signs of glaciation were seen on either of the islands, but some evidence of fluctuation in sea-level was noted on Gough Island.

Invertebrate Zoology

By M. W. Holdgate, Queens' College, Cambridge

About three thousand invertebrate specimens were collected during the six months on Gough Island, despite the fact that the author spent half his time in surveying. The sixty-seven main collecting stations were distributed to sample all the chief plant associations, over a wide altitudinal range. Some collections from similar types of vegetation were made on Tristan for comparison. On Gough, some freshwater localities were also sampled, and a study made of the littoral fauna of a typical 200-yd. stretch of rocky shore.

The terrestrial invertebrate fauna of Gough proved to be very poor and it is unlikely that more than a hundred and fifty species in all were collected. Many of the species that do occur are, however, very abundant and occupy a wide range of habitats. A few of the insects proved to be apterous or brachypterous, the most striking example of this condition occurring in an upland Lepidopteran superficially resembling the endemic *Dimorphinoctua cunhaensis* of Tristan[5]. It is likely that many of the species collected will prove to be endemic.

The littoral fauna was somewhat richer in species, and despite the small tide-range showed some zonation.

Vertebrate Zoology

By M. K. Swales, Magdalene College, Cambridge

Twenty species of 'sea birds', mostly of the order Procellariiformes, and none of them new records, were found to occur on Gough Island. Of these, seventeen species were shown to be nesting, some of them in great abundance. More than a thousand of these birds, including some of all species, were weighed and measured. A study was made of the wandering albatross (*Diomedea exulans dabbenena*), a subspecies almost confined in its breeding distribution to Gough Island. The two endemic species of land birds occurred commonly throughout the island and a special study was made of these. The bunting was found to be one species only (*Rowettia g. goughensis*) with five well-marked plumage stages, the youngest a speckled dark brown and the adults green in colour. The rail (*Porphyriornis c. comeri*) has distinct juvenile and adult plumages only (brown and black, respectively). Some live specimens of both species were brought back to England for further study.

More than 10,000 fur seals (*Arctocephalus pusillus*) were counted on the island's beaches. They are most abundant on the west coast, which is more storm beaten and less accessible than the east coast. Estimates were also made of the composition of the herds. The numbers of seals available for exploitation will be calculated from these figures.

A census was made of the elephant seals (*Mirounga leonina*) on the island. The total population is less than three hundred. In contrast to the fur seals, these are found mainly on the east coast on pebble and sand beaches.

Detailed accounts of the expedition's results in these fields of study will appear in the appropriate journals in due course.

We are most deeply grateful to H.R.H. the Duke of Edinburgh for his interest in the expedition and the support he has given it. We would also like to thank the Scott Polar Research Institute, the Royal Geographical Society, and all those other departments, societies, colleges, firms and individuals without whose aid the expedition could not have taken place.

NUCLEAR MAGNETIC RESONANCE AND ELECTRON SPIN RESONANCE

It is no new idea that most of the advances in the techniques of chemistry have come from the use of apparatus and methods originally devised by physicists. This is particularly true of spectroscopy, where the main applications associated with the different frequency bands have moved over, one after another, from the pure physicist to the chemist. As a result, ultra-violet and infra-red spectroscopy are now considered as subjects belonging to physical chemistry, and even γ-ray spectroscopy is finding considerable application in chemical research.

It would appear that during the past eighteen months a similar move has been taking place with the two new techniques of nuclear magnetic resonance and electron spin resonance. Both these subjects originated in the physics laboratories, and for several years after their initial discovery were applied to purely physical problems such as the determination of nuclear spins and moments. As with all techniques which study the interaction of atoms with external forces, it soon became clear that these new methods also had very great potentialities as tools for chemical investigation, and during the past few years these applications have been brought to light in a very striking way.

The increasing interest among chemists concerning the possible uses of these techniques was reflected by the decision of the Physical Methods Group of the Society for Analytical Chemistry and the Photoelectric Spectrometry Group to hold a joint meeting on the subject in Oxford on May 25. This meeting was timely, as it would appear that there are now quite a large number of chemists in Great Britain who are already aware that a new tool has become available, but many are not yet clear as to the precise applications and limitations of the new techniques. The meeting was divided into two sections with two speakers presenting papers on nuclear magnetic resonance and two presenting papers on electron spin resonance; in this way the apparatus and applications of each technique were brought clearly to light. This careful differentiation was found to be very necessary, as some confusion appears to exist between the two subjects. It was for this reason that the name 'electron spin resonance' was used to describe the resonance absorption associated with electronic transitions, instead of 'paramagnetic resonance'. Although the latter title has been widely used in the past few years, it can, in principle, be equally well applied to nuclear resonance absorption, and hence in order to avoid any confusion it was suggested that it would be wise to use the distinguishing titles of 'nuclear magnetic resonance' and 'electron spin resonance' in future chemical work.

Dr. R. Richards (University of Oxford) presented the opening paper introducing the general theory of nuclear magnetic resonance, and then outlining some of its main applications. He explained how nuclear resonance absorption can be obtained if a strong magnetic field is applied across a specimen containing nuclei with magnetic moments. These will then take up different quantized orientations in the magnetic field and, if radiation is fed to the specimen with a frequency such that $h\nu$ is equal to the energy difference between the quantized states, a resonance absorption will occur, which can be detected by a fall in the radiation transmitted through the system. For hydrogen nuclei in a typical field of ten thousand gauss, this resonant absorption will take place at a frequency of 42·6 Mc./s., and hence all the techniques associated with normal radio and television frequencies are used for generating and detecting the radiation. There are two great advantages of spectroscopy at these frequencies; the first is that line widths from liquid samples are extremely small, corresponding to 1 c./s. or 10^{-11} cm.$^{-1}$, and the second is that the frequencies of absorption can be measured with very high accuracy by normal radio techniques. As a result it is possible to determine nuclear gyromagnetic ratios and magnetic moments with very great precision, and it was soon found that the small changes in magnetic field produced by different electron configurations around the nuclei could be detected and differentiated. In this way it is possible not only to distinguish different elements and isotopes present in a compound, but also to differentiate between different groupings of the same element. The proton resonance of ethyl alcohol was shown as an example, as in this case the absorption is split into three main lines, one corresponding to the hydrogens of the CH_3 group, one to those of the CH_2 group and the other to those of the OH group. The occurrence of this 'chemical shift' often enables a detailed chemical analysis to be made, the whole operation only taking a few minutes. Several well-illustrated examples of this high-resolution work were given as applied to hydrogen, fluorine and phosphorus chemistry. It was also shown how a further splitting of the lines gives information on the positions of groups relative to each other, and hence structural as well as group analysis is thus possible.

Dr. M. Packard (Varian Associates, U.S.A.) then showed a series of slides giving details of the experimental techniques involved in high-resolution nuclear magnetic resonance, and illustrating some of the spectra actually obtained. The way in which the fine detail of the lines could be used to differentiate between various structural formulæ of the same compound was ably demonstrated, and in some cases it was even possible to distinguish excited triplet states. This high-resolution work requires a large and very well stabilized magnet, however, such that the field can be maintained homogeneous to 1 part in 10^8, and it is the cost of such equipment that is the main limitation on this work at the moment.

Dr. E. E. Schneider (University of Durham) then read a paper introducing the theory and technique of electron spin resonance, comparing and contrasting it with nuclear resonance. In electron spin resonance, the applied magnetic field acts on the magnetic moments associated with the unpaired electron spins, and since these moments are about a thousand times greater than those of the nuclei the resulting energy-level splittings, and hence frequencies of absorption, are correspondingly increased. Electron resonance absorption in a field of ten thousand gauss therefore occurs at about 30,000 Mc./s., and all the radio-frequency circuits of nuclear resonance are replaced by waveguides and other radar techniques. There is one great advantage in working at these high frequencies, namely, that the sensitivity of the technique is very much increased. The net absorption that is actually measured in either nuclear or electron resonance is the difference between the energy absorbed by the electrons or nuclei in the ground-state and the energy emitted from those in the excited state. This difference depends on the ratio of the numbers in the ground and excited states and will become larger the greater the energy splitting between the levels and the lower the temperature of the specimen. As a result of the much larger energy splitting associated with the electronic spin changes, the sensitivity is very much greater than that for nuclear resonance; and whereas protons can only be detected down to 10^{16} per gm., it is possible to detect, and measure the concentrations of unpaired electrons down to 10^{13} per gm., or 10^{-11} molar. It is this feature of high sensitivity which offers most promise in the chemical applications of electron spin resonance, as although it cannot compete with the general high resolution of nuclear resonance, it can measure trace paramagnetic constituents to far greater dilutions.

Dr. D. J. E. Ingram (University of Southampton) then presented a paper dealing with more specific and particular applications of electron spin resonance. The systems to which the techniques can be most readily applied are those containing stable unpaired electrons such as normal paramagnetic atoms and organic free radicals. It is possible, however, to obtain atoms or molecules which have been left with an unpaired electron as a result of irradiation or some similar process. Such atoms or radicals can then be studied by the normal techniques of electron resonance and detailed chemical information often obtained. Illustrations of some such systems were then given, including radicals formed by ultra-violet irradiation and then trapped in low-temperature glasses, and others formed by X- or γ-ray irradiation. In these cases, as with all electron resonance spectra, considerable information can often be obtained from the hyperfine splitting of the lines which arises from an interaction with the magnetic moments of the neighbouring nuclei. The distinctive hyperfine structure produced by different elements can also be used in such practical applications as measuring the concentrations of impurity atoms in semiconducting material. Other applications were also mentioned, such as following the progress of chemical reactions which proceed via a transient intermediate, and also the detailed structural information that can often be determined from the angular variation of the spectra in single crystals.

The discussion which followed the main papers was opened by Drs. D. H. Whiffen, C. A. Parker and D. J. Ferrett. One of the main questions raised was that of absolute calibration and reproducibility of results. It was suggested that the most accurate form of quantitative measurement was by comparison with the signal from a small amount of a standard sample placed in the same radio-frequency field. For work with free radicals, the use of auxiliary coils to increase the field around the standard specimen was mentioned, although the more general technique employing a substance such as ultramarine, which has its resonance slightly displaced from the free-electron value, is probably to be preferred. The applications of the relatively less expensive low-resolution nuclear resonance were also described since, although this cannot give the group analysis of the high-resolution work, it can be applied to quantitative determinations of isotope concentrations for more than a hundred different nuclei.

It would appear that there are in fact three distinct types of resonance spectroscope that should be of considerable use to the chemist. The first is that employing very high-resolution nuclear magnetic resonance. This can not only distinguish different isotopes but also differentiate between various groups and bond-types of the same element, and thus provide a detailed structural analysis from a few grams of liquid. The disadvantage of this type of apparatus is purely practical, as a twelve-inch diameter magnet with a very homogeneous field is required, at a cost of several thousands of pounds. If detailed chemical information is not required, however, and only a quantitative determination of the different elements present is needed, then low-resolution nuclear resonance is quite sufficient, and relatively inexpensive magnets can be used. It is also easier to apply more sensitive means of detection to the low-resolution apparatus, and concentrations down to 10^{16} protons per gm. can be measured.

As distinct from both of these, an electron-resonance spectroscope can be used wherever unpaired electrons occur in a chemical system. The sensitivity is very much greater than that of nuclear resonance, and the less expensive magnets can be employed. It should therefore prove a powerful and readily available tool for investigating such systems down to dilutions of 10^{-11} molar. It would appear that the main applications of this technique are going to be in the fields of free-radical and irradiation chemistry, and it will probably find as much use in the medical and biological sciences as in physical chemistry.

D. J. E. INGRAM

OBITUARY

Mr. E. B. Wedmore, C.B.E.

THE name of Mr. E. B. Wedmore, whose death occurred at the age of eighty years on June 16, is widely known in two very different spheres. He was in a very real sense a pioneer in the development of research associations, and he was an apiarist of great repute. Mr. Wedmore can properly be described as the architect of the structure of the British Electrical and Allied Industries Research Association (E.R.A.), which is one of the largest co-operative research organizations in Great Britain at the present time.

Born at Bristol in 1876, Wedmore received his early education at private schools. His first scientific education at the University College of Bristol was followed by a short course in civil engineering at the Finsbury Technical College, and then by the full course in electrical engineering at that College.

He joined the Bristol Corporation Electricity Works in 1895 as an assistant, but returned to Finsbury Technical College during 1896–99 as a lecturer and demonstrator, gaining the City and Guilds Silver Medal in 1896. During 1899–1919 he was design engineer with the British Thomson-Houston Co., Ltd., in London and Rugby, and during this time he took out a number of patents, mainly for switchgear.

A shortage of certain materials essential to the electrical industry arose in 1917 as a result of submarine warfare, and in order to foster the devising of means to minimize the effects of this shortage, an Electrical Research Committee (E.R.C.) was set up under the ægis of the British Electrical and Allied Manufacturers' Association and the Institution of Electrical Engineers; this was the forerunner of the British Electrical and Allied Industries Research Association. Mr. Wedmore was appointed director of the earlier body in 1919, and he became director and secretary of its successor upon the incorporation of that body in 1920. This post he held up to the time of his retirement at the end of 1944. In 1938 he was appointed C.B.E. in recognition of his services.

Wedmore's qualities of character and mind proved to be admirably suited to the task of building up and developing the young research association. He was a good judge of men and quickly gathered about him a group of able engineers and scientists. Scientific judgment and inventiveness he possessed himself in a high degree, and he had an inspiring fertility of mind. With all these qualities was coupled an extraordinary business acumen.

Wedmore's own field of scientific interest was wide; it accommodated such diverse topics as colour photography and the making of models of four-dimensional 'objects' as seen in three-dimensional space. His major contributions were to the art of circuit breaking and to improvements in switchgear. Crucial observations of some of the basic phenomena of circuit breaking were made with a simple high-speed camera devised by Wedmore, and as an outcome of these experiments came the invention, jointly with Dr. Whitney, of the air-blast circuit breaker and of the oil-baffle switch. Wedmore was active in the field of international standardization, and was a member of a number of committees of the International Electro-Technical Commission. He attended the first meeting of the Conférence Internationale des Grands Réseaux Électrique, which was held in Paris in 1921, and he was largely responsible for the establishment of the liaison committee of that conference, from which developed the present British National Committee.

Wedmore communicated a number of papers to the Institution of Electrical Engineers and he was awarded several of the major premiums of the Institution, namely, the John Hopkinson in 1915, the Institution Premium in 1918, and the Kelvin in 1929.

Wedmore was reticent in nature and somewhat austere in appearance. He was, however, under the surface, very human and generous and sympathetic to any in real trouble, and he had a deep sense of loyalty to colleagues. It is a tribute to Wedmore's insight and ability that he should have built up, as a pioneer, a successful co-operative research organization with little to guide him other than his own shrewd judgment and initiative. J. GREIG

THE death of Mr. E. B. Wedmore has removed a well-known and greatly respected personality from bee-keeping circles. Despite his heavy professional responsibilities when director of the British Electrical and Allied Industries Research Association, Mr. Wedmore managed to find time to practise bee-keeping, to which he applied his scientific training and research experience. Since his retirement a few years ago, beekeeping research had occupied an increasing proportion of his time and he was always eager to discuss new results and ideas and to help beekeepers and research workers in any way that he could.

In 1944 the Beekeeping Standards Committee of the British Standards Institution was formed, and Mr. Wedmore was the natural choice for its first chairman, a position he held with great distinction until his death. He also served on other committees of the Institution which dealt with the standardization of honey tins, honey jars, etc.

For many years Mr. Wedmore was a member of the Apis Club, several county beekeepers' associations and of the British Beekeepers' Association, of which he was president in 1946. He was, for some time, chairman of the Research Committee of the British Beekeepers' Association, and was an active member of the Council of the Bee Research Association since its formation in 1949. He was responsible for a number of the Association's researches which were carried out with the co-operation of beekeepers, notably on methods of management of colonies and on queen introduction.

He was also interested in establishing better standards for honey in Britain, and his re-examination of earlier work on the chemical and physical properties of honey led to new tables relating refractive index to water content. Further papers on the accurate determination of the water content of honeys were in preparation at the time of his death.

Mr. Wedmore's books, "A Manual of Beekeeping" and "The Ventilation of Bee-Hives", together with his booklet, "Successful Bee-keeping", will undoubtedly continue to be used by beekeepers for many years to come.

Although rather shy and reserved, Mr. Wedmore gave much time to helping other beekeepers by lecturing and in other ways. His lectures contained a great deal of original, constructive thought. He was always willing to reconsider his own views in the light of new work and was foremost in efforts to encourage beekeepers to do the same.

C. G. BUTLER

NEWS and VIEWS

Linnean Gold Medal: Prof. W. H. Lang, F.R.S.

THE award by the Linnean Society of London of the Linnean Gold Medal to Prof. W. H. Lang will be regarded with much satisfaction by botanists, and especially palæobotanists, throughout the world. Although in the earlier part of his scientific career his attention was mainly directed to the Pteridophyta and Bryophyta, he later concentrated on investigation of early Devonian plants. During the time he taught in the University of Glasgow his contacts with Robert Kidston inspired him with an interest in palæozoic plants and led to that fruitful collaboration with Kidston in the description of the Devonian plants found in the Rhynie Chert in Aberdeenshire. The results of this investigation, published in the *Transactions of the Royal Society of Edinburgh* between 1917 and 1921, have had a profound influence on our ideas about the evolution of vascular plants, perhaps more than any other palæobotanical discovery of this century. Prof. Lang has made many notable contributions to our knowledge of the morphology of the Pteridophyta and, after collaboration ceased with Kidston's death in 1924, he has continued to investigate early Devonian plants and has shown that important information can be obtained from apparently unpromising and fragmentary plant remains. In collaboration with Dr. Cookson, of Australia, he described the Silurian plants which are found in Australia, the earliest indubitable land plants. His published work, like that of Kidston, has always been marked by meticulous attention to accuracy and he rarely, if ever, makes a statement about a plant which is not clearly demonstrated by photographic reproduction. He has carefully avoided entering the field of speculative morphology, to which the discovery of the Rhynie plants added such a potent stimulus.

Pure Mathematics in the Imperial College, London: Prof. W. K. Hayman, F.R.S.

DR. WALTER K. HAYMAN, reader in analysis at the University of Exeter, has been appointed to a newly created University chair in pure mathematics at the Imperial College of Science and Technology, London. Dr. Hayman is a brilliant mathematician with an international reputation in his own field, and the value of the contributions which he has made in this field has been recognized by his election at the early age of thirty to a fellowship of the Royal Society. Since graduating in 1946, he has published a number of papers, largely concerned with the behaviour of the maximum modulus of an analytic function which satisfies certain specified conditions. Perhaps the most striking of his results relate to the celebrated conjectures of Bieberbach and Wiman. On one hand he has proved that, if a given function $f(z) = z + a_2z^2 + \ldots$ is schlicht in $|z| < 1$, then Bieberbach's conjecture that $|a_n| \leqslant n$ does hold for all but a finite number of values of n. By an appeal to the method of symmetrization and the idea of the transfinite diameter, he has shown, moreover, that the above is a special case of corresponding results for p-valent functions. Again, in an earlier paper he disproved a conjecture of Wiman by showing that, if $m(r)$, $M(r)$ denote the minimum and maximum moduli of a non-constant integral function, then the inequality $m(r) > M(r)^{-A \log\log\log M(r)}$ holds for some large values of r if $A = 2{\cdot}2$, but not always if $A = 0{\cdot}09$. In the course of a short career he has already gained many of the distinctions most coveted by mathematicians. These include the Smith's and Adams's Prizes at Cambridge as well as the Junior Berwick Prize of the London Mathematical Society. Dr. Hayman's early education was received at Gordonstoun School, whence he proceeded in 1943 as a Major Scholar to St. John's College, Cambridge. In 1947 he was elected a Fellow of his College and, after a short period as lecturer at King's College, Newcastle, joined the staff of University College, Exeter.

Physical Chemistry at Haifa : Prof. F. Kőrösy

DR. FRANCIS KŐROSY has been appointed head of the Section for Physical Chemistry at the Technion (Technical College), Haifa, Israel. The last two professors in this post were Prof. A. Samuel and Prof. J. Shereshefsky. The Hungarian authorities, in accord with their constant desire to further international cultural co-operation, have given permission to Dr. Kőrosy and his family to leave Hungary for Israel and take up his duties at the Technion, where he is expected to arrive in a few weeks time. Dr. Kőrosy studied at the Technische Hochschule at Karlsruhe and graduated there as Dipl.-Ing.Chem. in 1927. He was awarded a Ph.D. degree with first-class honours at the University of Budapest in 1929 after having worked under Prof. Zemplén in organic chemistry. He returned as assistant to Karlsruhe, working in the Departments of Dr. J. Tausz and Prof. E. Előd on problems of adsorption in connexion with textile chemistry. Returning to Hungary in 1931 he joined the staff of the Tungsram Research Laboratory at the United Incandescent Lamp Co. During his work in this institution he carried out fundamental research on barrier layer cells with the late Prof. P. Selényi and worked with Dr. I. Brody on krypton and on krypton-filled and pressurized incandescent lamps. He published several papers on different subjects of general and inorganic chemistry and invented a buffer preparation against gastric acid disorders. He visited the United States before the War and then returned to Hungary. After the War he became *Privatdozent* at the University of Budapest with applied physical chemistry as his subject and received the degree of *Candidate* in 1953. He has been teaching at the University ever since and has also taught at the evening courses of the Technical University for the past three years. His experimental work and published papers range from pharmaceutical chemistry through organic and inorganic problems, always emphasizing the physical chemist's point of view.

Directorship of the London Museum : Dr. D. B. Harden

THE directorship of the London Museum, which has been vacant since Prof. W. F. Grimes left to become director of the University of London Institute of Archæology (see *Nature*, January 7, p. 16), has been filled by the appointment of Dr. D. B. Harden, who since 1945 has been keeper of the Department of Antiquities and secretary of the Griffith Institute at the Ashmolean Museum, Oxford. Dr. Harden is at present vice-president of the Society of Antiquaries, and during 1950–54 was president of the Council of British Archæology. As honorary secretary of the Museums Association, he has also had much experience of museum problems outside Oxford. He has served on the Council of the British Association and was the recorder of Section H (Archæology) for a number of years. He is an expert on ancient glass. But all these activities, and many more, are of the kind that could be extracted from a book of reference. What would not be mentioned there is his tact and genial personality. It is not easy to be a well-liked and successful recorder of a section at meetings of the British Association. Not only have programmes to be arranged, but also during the meeting itself all the members have got to be kept contented. It may be added that, in this regard, Dr. Harden has always been ably seconded by Mrs. Harden. There can be no doubt that his appointment as director of the London Museum is a wise one, and will be popular.

Institute of Industrial Management : Awards

THE Bowie Medal for 1955 of the Institute of Industrial Administration has been awarded to Mr. E. F. L. Brech, management consultant and senior partner of Urwick, Orr and Partners, Ltd. The Medal, which was established in 1954, is awarded annually to a member of the Institute for a noteworthy contribution to management. Mr. Brech has been chairman of the London Centre of the Institute of Industrial Administration and is at present a member of council; he was founder-chairman of the Association of Supervisors' Discussion Groups.

The Institute has also awarded the Wilson Medal, and special premium of £25, for 1955/56 to Mr. C. R. Perks (Cardiff Branch) for his paper on the establishment of overseas subsidiaries; honourable mention has been given to Mr. N. G. Westcombe (London Branch) for his paper on emotional attitudes in management.

International Geophysical Year : Conference in Paris

THE Third Antarctic Conference of the International Geophysical Year was held in Paris during the past week. The United Kingdom delegation consisted of Sir David Brunt (secretary of the Royal Society), Mr. James Wordie, Dr. V. E. Fuchs and experts in those problems likely to be met in next year's Antarctic programme. The delegation presented a report on what has been achieved by the Royal Society advance party, the advance party of the Trans-Antarctic Expedition and the existing bases of the Falkland Islands Dependencies Survey. Other nations, including Australia, France, the United States and the U.S.S.R., also presented reports. The plans for the programme in Antarctica of the International Geophysical Year were discussed; arrangements for co-operation in radio communications, central weather forecasting services and mutual logistic support were considered.

Hazards of Nuclear and Allied Radiations

A SHORT debate in the House of Commons on July 16 on the report of the Committee on the Hazards to Men of Nuclear and Allied Radiations was opened by Dr. Edith Summerskill, who urged that it is of paramount importance not to increase the scale of the present tests of nuclear weapons and that control of such tests with the object of eventual abolition should be our aim. Mr. Richard Foot stressed the importance of the further research work on the genetic effects of radiation and other matters which the Committee recommends should continue, and Mr. A. Blenkinsop, asking whether research work in Britain is adequate, urged the importance of encouraging vigorously all the international research work proceeding in this field. The Minister of Health, Mr. R. H. Turton, replying in the debate, said that the Government regards the expansion of research as a matter of high priority in order that the potentialities of nuclear radiation may be exploited with confidence and safety; immediate action will be taken when the Committee submits to the Medical Research Council its recommendations for future work. The Atomic Energy Authority would have no difficulty in carrying out the recommendations of the report regarding occupational exposure to radiation. He reiterated the Government's intention to do its best to secure progress in the regulation and limitation of test explosions, and mentioned that the Radioactive Substances Advisory Committee, under the chairmanship of Sir Charles Darwin, has prepared a comprehensive code of practice for use in the National Health Service hospitals. This is under final revision and will be issued shortly. To assist in carrying out the code, as well as in applying existing protective measures in hospitals and in industry, a Radiological Protection Service has been set up and, in accordance with the recommendation that present practice in diagnostic radiology should be reviewed and the use of radiotherapy in non-malignant condition critically examined, the Government is appointing a committee of scientists and professional men, with Lord Adrian as chairman, to examine these essentially clinical matters and make recommendations. Recommendations for collecting more detailed information for genetic studies would be discussed with the Registrar General.

A Winge Festschrift

A VOLUME in honour of the seventieth birthday of the distinguished Danish botanist, Prof. Öjvind Winge, of the Carlsberg Laboratory, Copenhagen, has recently appeared (as Vol. 26 of the *Comptes Rendus des Travaux du Laboratoire Carlsberg*, Sér. Physiologique; pp. 1–443; 1956; 40 kr.). As is appropriate and to be expected, it is concerned almost entirely with the genetics of micro-organisms. It includes a bibliography of Prof. Winge's own scientific publications, these amounting to 120 titles, extending from the year 1907 to date, the whole constituting a notable contribution to a subject of great contemporary interest and increasing importance. The individual papers in the volume have been contributed by eminent exponents in the field of the genetics and physiological genetics of micro-organisms. Some of these relate to specific topics and observations; for example, gigas mutants; others pertain to what is now referred to as the biochemistry of genetics, for example, "The Genetics of Galactose Fermentation in *Saccharomyces* Hybrids"; and yet others deal with more general topics, such as "Genes—their Nature and Function". Altogether, there are twenty-five separate contributions, the overall effect being to provide the reader not only with a representative survey but also to give him a very lively impression of the effort that is being made in different parts of the world in a difficult but rewarding field. Like other publications from the Carlsberg Laboratory, the volume is attractively produced.

Journal of Fluid Mechanics

THE recent increase in the number of investigations, both theoretical and experimental, relating to the study of fluid mechanics has necessitated the launching of a new periodical devoted solely to this subject, the *Journal of Fluid Mechanics*. The *Journal* is to be issued in six parts to a volume of approximately six hundred pages, and the first number has recently been published (London: Taylor and Francis, Ltd.; New York: Academic Press, Inc. 20*s*. or 3 dollars per part; £5 10*s*. or 16.50 dollars per vol.). The editor is Dr. G. K. Batchelor (Cavendish Laboratory, Cambridge), assisted by Drs. T. B. Benjamin and I. Proudman; and Profs. G. F. Carrier (Harvard), W. C. Griffith (Princeton) and M. J. Lighthill (Manchester) are associate editors. The first issue contains eight papers, all of which are of high standard: four relate to aerodynamics, one to oceanography, one to rainfall, and the remaining two, by M. J. Lighthill and M. B. Glauert, respectively, of the Department of Mathematics, University of Manchester, deal with the theoretical discussion of drift and boundary-layer flow on oscillating plates and cylinders, respectively. M. D. Van Dyke (Ames Aeronautical Laboratory, California) obtains a second approximation to the solution of the problem of supersonic flow past unyawed elliptic cones by proceeding from the slender-body theory. L. C. Woods (Sydney) discusses the thrust due to an air-jet flowing from a wing placed in a wind tunnel and establishes that the ideal thrust is almost independent of the jet exit angle; V. Blackman (Princeton) describes a study of vibrational relaxation in oxygen and nitrogen in the range of shock waves of Mach-number speeds 3–10; and N. Rott (Cornell) investigates theoretically the diffraction of weak shock waves near the edge of a sharp wedge. A theory of collisions between small drops in a turbulent fluid, taking into account collisions between equal drops, is given by P. G. Saffman and J. S. Turner (Trinity College, Cambridge), and the results are applied to the case of small drops in atmospheric clouds to test the importance of turbulence in initiating rainfall. Finally, J. Grease (National Institute of Oceanography, Dorking) considers the problem, arising in connexion with the propagation of tides and storm surges in the ocean, of long gravity waves on a rotating Earth approaching a semi-infinite barrier parallel to the wave crests.

Health Education in Factories

THE health committee of the County Borough of Willesden (London) has been considering means of interesting people in health education (*Health Educ. J.*, 14; 1956). During the past seven years, health talks on a variety of subjects have been given to religious, social and political organizations, trade unions, and many clubs. The audiences have varied from about twenty to eighty; but there has recently been a tendency for them to decline. Some talks had already been given in factories by special requests from the managements, and it was thought that here appreciative audiences might be found. At the end of 1954 it was decided to explore the possibility of giving health talks to factory staffs during lunch-hour breaks. Several factory managements were approached and the response was most encouraging. Four talks were given by the Medical Officer of Health to approximately 2,400 factory workers, the attendances ranging from 400 to 1,000. A new drive was made in 1955, and in the first six months of the year fourteen talks were given in factories on subjects including influenza, coughs and colds; cancer; mass miniature radiography; nutrition; accident prevention and sepsis. With the outbreak of poliomyelitis in the beginning of July 1955, a new stimulus was given to the work. Most factories were only too willing to provide facilities for a talk on this subject, and some of them approached the health department direct. Altogether, up to the end of October, ninety-six talks were given in eighty factories to 23,500 workers. The number in the audience varied from 20 to 4,000, with the majority in the range of 100 to 200. Co-operation with the factory management was not easy at first. Personal contact with the personnel or works manager was necessary.

Row-crop System for Grass

THE technique of growing grass in wide rows instead of in broadcast stands was first developed for grass, chiefly cocksfoot, intended for seed production. Coupled with heavy dressings of nitrogen, part of which was applied in late summer, this system was found to give increased yields of seed and, incidentally, to prolong the growing season well into the winter. With the post-war drop in seed prices, the emphasis has changed and the interest now lies in how the row-crop system may best be used by the grazier. Some account of Scottish experiences with the method is given by I. V. Hunt in an article entitled "Rowcrop Grass", published in the autumn number of *Scottish Agriculture* (Edinburgh: H.M.S.O.; 1*s*.). The grass is sown in strips 12–28 in. apart, with inter-row cultivation in the initial stages. In the summer the crop is grazed or cut for hay, silage or dried grass. Fertilizer is then applied and later growth kept for winter grazing. Cocksfoot has so far proved the most suitable grass; but trials are in progress with timothy, meadow fescue and perennial ryegrass. A seed crop should be possible from cocksfoot and meadow fescue without prejudicing the winter grazing, but timothy would ripen too late. Other promising features of the system are the reduction in waste from treading, winter burning, or rotting, earlier growth in spring and considerable reduction in the cost of seed. The method is still in the experimental stage; but it has steadily gained favour on English and Welsh farms and may prove of special use in Scotland where the grazing season is normally short.

Cultivation of Lucerne in Britain

THE acreage under lucerne in England and Wales has now reached some 112,000 acres, half of which lies in East Anglia, Kent and Lincolnshire. The crop requires skill in management and makes heavy demands on soil fertility; but its drought-resistant properties and vigorous growth during the summer make it a valuable plant for the establishment of leys, and it can be profitably grown in all parts of Britain. Memoir No. 1 of the Grassland Research Institute, entitled "Lucerne Investigations 1944–1953" (pp. 81; from the Institute, Hurley, near Maidenhead, 1955; 10*s*.), should help farmers to utilize this crop better, for it gives the results of critical field experiments carried out by the Institute and the National Agricultural Advisory Service in different parts of the country. Information regarding the different strains of lucerne is provided in an article contributed by the National Institute of Agricultural Botany, Cambridge; from the trials at the Grassland Research Institute, the early long-season type appears to have given the most promising results so far. Much attention is devoted to the subject of management, including that of leys where the lucerne is associated with different companion grasses. Remarkable differences in yield can be obtained by changes in timing the cuts, autumn being a specially critical period. A useful bibliography is included in the memoir.

Germination Regulation in Desert Seeds

THE regulation of germination in the seeds of the desert leguminous species *Colutea istria* Mill. has been investigated in some detail by D. Koller and M. Negbi (*Bull. Res. Council Israel*, Sect. D, Botany, **5***D*, 1, 73; 1955). The seeds were found to be largely impermeable to water. This could be remedied either by treatment with concentrated sulphuric acid, or by vigorous shaking in a glass jar. Swelling was more rapid after the former treatment. It was found that, whereas acid treatment removes impermeability by acting all over the surface of the seed coat, the shaking did so only in the micropylar region. Permeable seeds germinated equally well in light and in dark, and their germination was insensitive to temperature between 20° and 30° C. Seedling growth in dark exceeded that in light. The two seed samples investigated, which were collected in different years and locations, differed widely in germination. This was apparently caused by different degrees of maturity which the embryos had attained before fruit ripening. Two separate coats surround the embryo. The inner coat has no influence on germination in the fully 'ripe' sample, but in the 'unripe' sample it affords the embryo some kind of protection against decay. The outer coat in both samples contains a water-soluble growth inhibitor, which retards embryo growth. Successful reseeding of depleted desert pastures was carried out with this species in the Negev Highlands.

Nuclear Differences in Onion Root Tissue

IN former years it was generally assumed that the cells of the various tissues of a higher plant had nuclei the constitution of which was identical with that of the fertilized ovum. Some recent investigations have shown, however, that the nuclei in all cells are not alike. A. L. Chouinard (*Canad. J. Bot.*, **33**, No. 6, 628; 1955) has contributed to this topic by observing the nuclear differences in onion (*Allium cepa*) root tissues as revealed by the induction of mitosis with indoleacetic acid. Treatment with this growth substance was used for stimulating mitosis in differentiated tissues of *Allium cepa* roots in order to establish whether nuclear differences, specifically in chromosome number, exist normally and are merely revealed by treatments, or whether these nuclear differences are produced by the treatment. With the concentrations of indoleacetic acid and durations of treatment used, evidence was obtained that chromosome number differences exist in the differentiated tissues of onion root prior to any treatment, and that the appearance of these differences after treatment is a matter of revelation and not of causation. The evidence obtained in these investigations comes indirectly from observations of nuclear size and structure and directly from rare spontaneous mitoses in untreated roots, and in the treated roots (1) from the absence of nuclear abnormalities which might explain otherwise the origin of polyploid cells, (2) from the uniform occurrence of certain chromosome numbers in specific root tissues, (3) from proportions of diploid and polyploid divisions during mitotic induction, and (4) from the lack of relationship between total mitotic activity and number of polyploid mitoses. A gradient of endomitotic polyploidization exists in certain tissues along the longitudinal axis of the onion root.

Rubber Diseases in the Belgian Congo

R. J. Pichel (with the collaboration of C. Maertens) has produced a monographic study of rubber diseases and their control in the Congo basin (l'Inst. Nat. pour l'Étude Agr. du Congo Belge, Sér. Tech. No. 49 ; pp. 1–450, 1956 ; 400 fr.). The first part of the book deals with the general problem of disease in rubber and the causative agents, the root-attacking fungi *Fomes lignosus* (*Rigidoporus microporus*) and *Armillaria mellea* being of outstanding importance, as they also are in other rubber-growing regions. The attitude of the author to his subject is practical rather than detailed and specialized. The second part is devoted to observations on the biology of root-destroying fungi and the behaviour of *Hevea* under attack. The problem of infection courts is given special attention, and the processes and factors involved in contamination, infection and effective parasitism are considered at some length. In the third section, the epidemiology of the diseases and the efficacy of control measures are described with special reference to the considerable volume of work carried out at Yangambi, the effects of both direct methods and cultural treatments in controlling the pathogens being considered. The fourth section is concerned with control measures and the economic aspects of the problem. The conclusions and recommendations at the end represent a synthesis of the experience and the effort made in this field by the Belgian Congo workers at the Yangambi Research Station during recent years. The work is illustrated by a large number of excellent photographs, coloured plates and diagrams. This monograph contains a great deal of new observation of interest and importance to both pathologist and planter. A bibliography of more than three hundred titles is included.

Breeding of Shags on Lundy Island

During 1954 and 1955 observations were made on the breeding habits of shags on Lundy Island, and these have been described in the ninth annual report of the Lundy Field Society. Sufficient material was collected for some factors to emerge which appear to affect breeding success. The two years showed practically no difference in the pattern of clutch size although the weather was dissimilar. In both years there was a great predominance of clutches of three ; there is a tendency for clutches laid later in the breeding season to be of a size greater, or less, than three. There was a striking similarity of hatching and fledging success in the two years, 93·6 per cent of young hatched during the two years reaching the flying stage—a remarkably high percentage. Even so, the number of young fledged was not sufficient to secure replacement of breeding adults. From the evidence of recoveries the yearling mortality is fairly high, and the species appears not to breed until at least three years old. Adults must average several seasons of breeding in order to replace themselves. All nests found have been divided into those situated under rocks and those open to the sky or with only slight rock overhang : covered nests are significantly more successful than open nests. Young in covered nests have shelter from rough weather and seas, and are not liable to be inadvertently pushed out of the nest and possibly over the cliff. Another significant factor in fledging success is the date of hatching. The earlier nests have a markedly higher rate of success than the late nests. It will be interesting to compare these results with those obtained by E. White and J. C. Coulson, who are studying shag mortality on the Farne Islands.

Zoological Nomenclature

As from December 12, 1956, the International Commission on Zoological Nomenclature will start to vote on the following cases involving the possible use of its plenary powers for the purposes specified against each entry. Full details have already been published (*Bull. Zool. Nom.*, 12, Pts. 1 and 2 ; June 1956). (1) *Paradoxides* Brongniart, 1822, validation ; *Olenus* Dalman, [1827], designation of type species for ; *paradoxus* Linnaeus, 1759 (*Entomolithus*), suppression and Paradoxiden Emmrich, 1844 (wrongly based on *Olenus*) suppression (Cl. Trilobita) ; (2) *munda* Kuhl, 1820 (*Proc.[ellaria]* and *Nectris*), suppression (Cl. Aves) ; (3) *Daira* de Haan, [1833], validation (Cl. Crustacea, Order Decapoda) ; (4) *tuberculatus* Hall, 1859 (*Acidaspis*), validation ; *Acanthaloma* Conrad, 1840, suppression (Cl. Trilobita) ; (5) *Theridion* Walckenaer, 1805 (Cl. Arachnida), designation of type species for ; (6) *Protopeltura* Brogger, 1822 (Cl. Trilobita), designation of type species for ; (7) *punctata* (*Querquedula*), validation of, as from Sclater (P.L.), 1880, as name for the hottentot teal (Cl. Aves) ; (8) *Trinucleus* Murchison, 1839, validation of ; *tuberculatus* Link, 1807 (*Trinucleus*), suppression (Cl. Trilobita) ; (9) *Panulirus* White, 1847, validation ; *commune* Leach, 1818 (*Phyllosoma*) and *rissonii* Desmarest (*Palinurus*), suppression (Cl. Crustacea, Order Decapoda) ; (10) *Illaenus* Dalman, [1827], protection of by suppression of *Cryptonymus* Eichwald, 1825 (Cl. Trilobita). Comments should be sent as soon as possible to the secretary to the Commission, Mr. Francis Hemming, 28 Park Village East, Regent's Park, London, N.W.1.

Ordnance Survey Map of Roman Britain

Britain was under Roman rule for nearly four hundred years, and, though subsequent influences from beyond the North Sea and from Normandy profoundly affected its people and their way of life, yet in many things the Roman pattern remained an ideal. A detailed survey of the various categories of Roman remains is therefore of great interest, and the new, third edition of the "Ordnance Survey Map of Roman Britain" is very welcome (pp. 43+1 map ; paper flat, 3*s*. 3*d*. ; folded, with text, 7*s*. 6*d*. ; text only, 3*s*.). Much has been discovered since the last edition appeared about a quarter of a century ago, and methods of investigation have vastly improved. In every way the present publication is a great advance on the last, and Mr. C. W. Phillips, archæological officer for the Survey, is to be congratulated. It is a pity, perhaps, that such a large map had to be printed on such thin paper. It will not stand much use away from the study table, unless extracted and framed. A map of such general interest might well have been issued on paper of such a quality that it would stand up to use in the field by the investigator and by the amateur when travelling about the country. But it is a fine piece of work, and it will be a long time before another revise is needed.

Distribution of Prehistoric Rock Engravings and Paintings in South Africa

AN up-to-date gazetteer of all the sites in the Union of South Africa and South West Africa where rock-shelter paintings and engravings on rocks occur was prepared by the late Prof. C. van Riet Lowe and has been published by the Archæological Survey of the Union under the title: "Distribution of Prehistoric Rock Engravings and Paintings in South Africa" (Archæological Series No. 7. Pp. 58. Johannesburg: Union Education Department, 1956; 10*s*.). The arrangement is by provinces and districts, which makes it easy to use, especially as there is a foreword where the various groups are described. The publication will be very useful to prehistorians visiting South Africa and wishing to study a number of painted and engraved sites. There is an excellent distribution map.

Measuring the Load on Pit Props

FROM the earliest days of mining the support of the roof of the tunnel driven has been a question of the first importance. With the ordinary handwork at the pit face, it had come to be accepted in Western Europe that the coniferous pit prop was the safest that could be obtained, as it gives warning before breaking to collapse. Metal substitutes have had a brief trial; but they give no such warning. The successful development of mechanized systems of mining have brought other difficulties, and the wooden coniferous pit prop is no longer free from suspicion. This matter is dealt with in *Science Bulletin* No. 4 (Spring 1955) of the Scientific Department, National Coal Board (pp. 24; from the Board, London). Some sound roof control is of paramount importance, if mechanized systems of mining are to be introduced and accepted, to prevent falls of the roof on the coal face, and also to improve the workability of the coal seam. Attempts have been made in the past to undertake a complete study of roof control, entailing the measurement of the forces acting actually within the coal and the surrounding strata, but considerable problems are involved. Information can, however, be obtained from a study of the movements of the roof supports and of the loads they carry. For example, a study of the loads carried by the front row of props will help to show whether a prop-face front can be used. An instrument, called a load cell, has been devised which will register the load carried by a prop when placed between the prop and a roof bar. The load cell is small and robust, so that it can be set easily and will not interfere with the normal behaviour of the prop, and already it has been used for a number of investigations.

Seismic Observations on a Large Explosion in North-East Japan

ON September 13, 1953, at 3h. 4m. 57·074s., the second large explosion at the Kamaisi mine of the Nippon Iron Works (lat. 39° 17′ 39·9″ N., long. 141° 41′ 32·9″ E.) to be observed seismically occurred, this being the fifth explosion to be observed seismically by the Japanese Research Group for Explosion Seismology (*Bull. Earthquake Res. Inst., Tokyo Univ.*, 33, Pt. 4, 699; December 1955). The aim of the blasting operation was to remove dangerous gangue rocks as a safety measure, and the letting off of 42 tons of explosives was operated in seven steps, which took altogether 84 milliseconds from first to last. From a seismic point of view, this method is less effective than if the whole mass had been let off at once. Fourteen seismograph stations for refraction shooting were placed from near the shot point to a distance of 332 km., the most sensitive instruments being placed 170–332 km. distant. Most of the seismographs used were vertical electromagnetic instruments, working at 3 c./s., though the nearest worked at 10 c./s., and an additional one at the most distant station worked at 0·7 c./s. Horizontal electromagnetic seismographs were operating at six stations, working either at 3 c./s. or 1 c./s. The line of fourteen stations was almost parallel with, and near, the east coast line from about lat. 36° 33′ N. to about lat. 39° 18′ N. In addition, a special station was established at Umanokiuti ($\Delta = 4{\cdot}63$ km.) to make observations of reflected waves. *P*- and *S*-wave onsets were read at most stations, and travel-time curves constructed from the results. On the assumption of horizontally disposed layers, the *P*-wave indicated a layer of thickness between 22 and 25 km. in which the velocity was 6·05 km./sec., overlying a layer in which the velocity of *P*-waves was 7·2–7·6 km./sec. Reflexion experiments tended to confirm this thickness for the upper layer. Results from the *S*-wave alone gave a thickness of between 32 and 36 km. for the upper layer in which the velocity of the *S*-wave was 3·46 km./sec., overlying a stratum in which the velocity of the *S*-wave was between 4·5 and 4·8 km./sec. The discrepancy in the estimate of thickness of the upper layer may be due to the influence of a more complicated structure than that assumed. This is to be investigated.

Scientific Instrument Manufacturers' Association: Officers for 1956–57

THE following have been elected officers for 1956–57 of the Scientific Instrument Manufacturers' Association: *President*, G. A. Whipple (Hilger and Watts, Ltd.); *Vice-President*, P. Goudime (Electronic Instruments, Ltd.); *Honorary Secretary*, J. E. C. Bailey (Baird and Tatlock (London), Ltd.); *Honorary Treasurer*, C. H. Warner (W. F. Stanley and Co., Ltd.); *New Members of Council*, F. W. Dawe (Dawe Instruments, Ltd.), P. J. Ellis (R. B. Pullin and Co., Ltd.), J. M. Furnival (Marconi Instruments, Ltd.), D. F. Newstead (Kershaw Division, Rank Precision Industries, Ltd.), J. A. Stafford (Taylor, Taylor and Hobson, Ltd.), W. H. Storey (Unicam Instruments, Ltd.) and N. Trepte (Griffin and George, Ltd.).

University of London

DR. L. A. ELSON, British Empire Cancer Campaign Intermediate Research Fellow, has been appointed to the University of London readership in biochemistry tenable at the Institute of Cancer Research, Royal Cancer Hospital, London. The title of professor of experimental pathology (histopathology) in the University of London has been conferred on Dr. E. S. Horning, in respect of his post at the Institute of Cancer Research, Royal Cancer Hospital, and that of reader in physical organic chemistry in the

University of London on Dr. Victor Gold in respect of his post at King's College. The title of professor emeritus in the University of London has been conferred on the following on their recent retirement from chairs tenable at the institutes indicated: Prof. H. Berry (pharmaceutics at the School of Pharmacy); Prof. V. G. Childe (prehistoric European archæology at the Institute of Archæology); Prof. S. J. Davies (mechanical engineering at King's College); Prof. S. J. Cowell (dietetics at University College Hospital Medical School); Prof. H. T. Flint (Hildred Carlile chair of physics at Bedford College); Prof. L. Hawkes (geology at Bedford College); Prof. W. J. John (electrical engineering at Queen Mary College); Prof. A. Meyer (neuropathology at the Institute of Psychiatry); Prof. A. J. S. Pippard (civil engineering at the Imperial College of Science and Technology); Prof. H. Raistrick (biochemistry at the London School of Hygiene and Tropical Medicine); and Prof. R. A. Webb (pathology at the Royal Free Hospital School of Medicine).

Oversea Service Division, Colonial Office

The following appointments have recently been made in the Oversea Service Division, Colonial Office: C. J. Allen (agricultural officer, Jamaica), senior livestock officer, Department of Agriculture, Jamaica; E. J. H. Berwick (senior agricultural officer (grade A), Federation of Malaya), director of agriculture, North Borneo; A. E. Billington (senior research officer (grade B), Federation of Malaya), senior research officer (grade A), Federation of Malaya; F. B. Brown (botanist, Federation of Malaya), senior research officer (grade B), Federation of Malaya; P. G. Coleman and P. A. Gething (senior agricultural officers (grade B), Federation of Malaya), senior agricultural officers (grade A), Federation of Malaya; C. North-Coombes (agricultural economist, Gold Coast), assistant director of agriculture, Gold Coast; J. K. Coulter (soils chemist, Federation of Malaya), senior research officer (grade B), Federation of Malaya; W. H. Edwards (agricultural officer, Uganda), assistant director of agriculture, Uganda; J. H. Gisborne (assistant director of agriculture (research), Northern Region, Nigeria), deputy director of agriculture (research), Northern Region, Nigeria; W. C. H. Hill (senior agricultural survey officer, Department of Agriculture, Gold Coast), principal agricultural officer, Department of Agriculture, Gold Coast; H. M. James (agricultural officer, Federation of Malaya), senior agricultural officer (grade B), Federation of Malaya; G. B. Kennard (senior field officer, British Guiana), deputy director of agriculture, British Guiana; M. D. ffrench-Mullen (managing director, Berbice Fibre Research Co., Ltd., British Guiana), deputy director of agriculture, British Guiana; H. J. Simpson (senior agricultural officer (grade A), Federation of Malaya), assistant director of agriculture (field), Federation of Malaya; D. Westwood (senior agricultural officer, Gold Coast), principal agricultural education officer, Gold Coast; P. St. J. Matthews (forester (grade II), Kenya), assistant conservator of forests, Kenya; D. S. P. Noakes (deputy director of forestry, Federation of Malaya), director of forestry, Federation of Malaya; B. E. St. L. Stuart (research officer, Forestry Division, East Africa High Commission), assistant conservator of forests, Kenya; L. C. M. Wedderburn (senior assistant conservator of forests, Northern Region, Nigeria), conservator of forests, Northern Region, Nigeria.

Announcements

Prof. Sydney Chapman, visiting professor of geophysics in the University of Alaska, has been awarded by the Accademia Nazionale dei Lincei, Rome, the international prize, on the Antonio Feltrinelli Foundation, for astronomy, geodesy, geophysics and their applications.

Sir Harold Spencer Jones has been appointed secretary-general of the International Council of Scientific Unions in succession to Prof. A. V. Hill, who has retired.

Mr. I. Edward Garrick, chief of the Dynamic Loads Division, Langley Laboratory, Virginia, of the U.S. National Advisory Committee for Aeronautics, has been appointed to the Jerome Clarke Hunsaker chair at the Massachusetts Institute of Technology. This chair, which is for aeronautical studies, is held for a year, and the previous occupant was Prof. W. Hawthorne, professor of applied thermodynamics in the University of Cambridge. Mr. Garrick is a leading authority on aircraft 'flutter'.

The autumn meeting of the Institute of Metals will be held this year in Germany during September 17–25. The meeting will consist of a large number of excursions to engineering works and other places of interest, and will be based in Stuttgart until September 23, and in Frankfurt am Main thereafter. During September 17–18 joint scientific sessions will be held with the Deutsche Gesellschaft für Metallkunde. Registration forms can be obtained from the Secretary, Institute of Metals, 17 Belgrave Square, London, S.W.1.

The fourth instruments and measurements conference and exhibition, organized by the Royal Academy of Engineering Sciences and the Swedish Association of Technical Physicists, will be held in Stockholm during September 15–23. The conference will consist of six sections: nuclear instrumentation; automation; physical methods for chemical analysis; spectroscopy; optics; and computers. Further information can be obtained from the conference secretary, Sven Malmström, P.O. Box 12035, Stockholm 12.

An international congress of clinical chemistry will be held in New York City during September 9–14 under the auspices of the International Federation of Clinical Chemistry and the Commission of Clinical Chemistry of the International Union of Pure and Applied Chemistry. The principal theme of the congress will be the significance of metabolic systems in clinical chemistry. Further information can be obtained from the congress secretary, Dr. John G. Reinhold, 711 Maloney Building, Hospital of the University of Pennsylvania, Philadelphia 4, Pa.

The Department of Civil and Municipal Engineering of University College, London, is offering two courses in photoelasticity. The first is a short refresher course, which will be held during September 3–14 (fee £8). The other is a full course extending over the academic year 1956–57, and comprises weekly lectures on the theory and methods of photoelasticity (fee, £14) with, when possible, one or two days a week practical work in the laboratories (fees, £11 and £16 respectively). Applications should be made to the Secretary, University College, London, Gower Street, W.C.1.

NEW NATURE RESERVES IN BRITAIN

THE Nature Conservancy has announced the establishment of two new nature reserves in England and the addition of further areas to two existing reserves. The new reserves are Lullington Heath (three and a half miles north-west of Seaford, Sussex) and Cothill (five miles south-south-west of Oxford), and the additions are to the Newborough Warren and Ynys Llanddwyn nature reserve, Anglesey, and the Axmouth–Lyme Regis undercliffs nature reserve, Devon.

Lullington Heath is one of the largest areas of unploughed chalk heath remaining on the South Downs. It was under cultivation in prehistoric times, and the boundaries of rectangular fields can still be traced, especially in the north-west corner of the reserve. Fragments of pottery and iron slag show that people not only farmed but lived and worked there. Far from reducing the biological value of the reserve, these traces of long-past soil disturbance add to its interest, and provide a link with agricultural history. The reserve covers an area of 155 acres and is being declared under a sub-lease from the Forestry Commission, which leases the area from the Eastbourne Waterworks Company. It appears that the land has been used only for grazing, without cultivation, for many hundreds of years; the lime has been leached from the surface layers, which are acid, even though the chalk is only a few inches below. In consequence, shallow-rooted plants which need acid soil—for example, bell heather and ling—are mingled with deep-rooted plants such as salad burnet and dropwort, which need limy soil. By April 1954 myxomatosis reached Lullington and almost exterminated the formerly dense rabbit population, and this set in motion changes in the vegetation. Careful records have been made of these changes, which form an important part of the national record of the results of myxomatosis. It is important that the long-term research work which is in hand on this reserve should not be disturbed, and applications for collecting specimens of animals or plants or changing the fauna or flora in any way should be made to the Conservancy's regional officer for the south-east at 19 Belgrave Square, London, S.W.1.

The Ruskin Reserve at Cothill, Berks, has been protected since 1917 by the National Trust in co-operation with the Ashmolean Natural History Society, and it has been declared a nature reserve under a lease with the National Trust. Four and a half acres in extent, it has long been noted for the richness of its flora and fauna and is used for university teaching and research, together with other adjoining areas, for the protection of which the Nature Conservancy is negotiating. The fen occupies a basin, on the edge of the Jurassic (Corallian) Calcareous Grit, which is the meeting point of several streams carrying highly calcareous water; the outflow is at Sandford Brook. It seems probable that much of the valley was flooded in medieval times; two ponds can still be found in the Ruskin Reserve. These show the succession from open water through various swamp associations to woodland of alder, birch, ash and other trees, the development of the vegetation being accompanied by progressive acidification of the surface peat. Access to the reserve will be by permit only, applications for which should be made to the Conservancy's regional officer for the south, at the Furzebrook Research Station, Wareham, Dorset.

The Newborough Warren and Ynys Llanddwyn nature reserve, covering an area of 283 acres, was declared in June of last year, and the present declaration, which is made under a lease with the Glynllivon Estate, adds a further 500 acres extending from Rhosddu Lake up to, but not including, Abermenai Point. Although in Anglesey, it is only some three miles west of Caernarvon across the Menai Strait. Newborough Warren is one of the largest, and biologically richest, expanses of dunes in western Britain. A large-scale encroachment of the land by inundation of sea and sand was recorded in 1331; as a result of the planting of marram grass, the dunes have progressively become more stabilized, and some of them now rise more than 50 ft. above sea-level. It is one of the earliest occupied sites in Anglesey, and Mesolithic flint sites show occupation by man probably between 7000 and 5000 B.C. Stages of sand-dune succession are shown on a large scale, including shifting dunes, willow dunes, and marsh and fixed dunes. There are extensive 'slacks'—damp dune hollows—which are occupied by open communities of creeping willow. The 'slacks' are rich in plant life, some rarities being recorded and some species which are normally associated with mountain habitats. The dunes are important for biological and physiographical research and are much used by workers, especially from the University College of North Wales, Bangor. There will be no restriction on rights of way, but to collect specimens permission is needed from the conservation officer, c/o School of Agriculture, University College of North Wales, Memorial Buildings, Bangor, Caernarvon; the warden for the reserve is Mr. R. D. P. Morgan, Serai, Malltraeth, by Bodorgan, Anglesey.

The Axmouth–Lyme Regis undercliffs nature reserve extends over Bindon, Dowlands, Pinhay and Ware Cliffs, in Devon, and was established by the Conservancy in March of last year. There was then a large gap in the middle of the reserve which has now been filled by the additional area of 86 acres recently declared under a lease with the Governors of Allhallows School. This consists of the Rousdon and Charton Cliffs, and brings within the reserve the whole of the undercliffs stretching along 6½ miles of coast and covering 794 acres. The reserve is the largest and most important landslip area on the coast of Great Britain, records dating from the sixteenth century showing that there have been periodic slips of the Chalk and underlying Greensand on the Gault and Lower Lias Clays which dip towards the sea. The most spectacular slip recorded was at Dowlands on Christmas Day, 1839, when nearly eight million tons of rock subsided from a cliff 375 ft. high, leaving a vast chasm half a mile long and ranging from 200 to 400 ft. in width. The mixture of a wide range of rocks, which are mainly typical of south-eastern England, has led to a great variety of soils. Although between 1839 and 1905 very few trees established themselves on the floor and the sides of the chasm near Dowlands, since 1905 a fine isolated natural ash wood has come to maturity, this being almost the only known instance of the production of a mature ash wood on a virgin site without human interference within a precisely known period of time. Similar, but less striking, growth of natural vegetation has occurred on the Rousdon and Charton Cliffs. Owing to the inaccessibility of much of the ground and the continued risk of further slips, there has been an almost unique freedom from human disturbance there. Permits to collect specimens or to visit parts of the reserve away from the footpath will be needed, application for which should be made to the Conservancy's regional officer for the south-west at the Furzebrook Research Station, Wareham, Dorset; the warden for the reserve is Mr. L. A. Pritchard, Lynch Cottage, Rousdon, near Lyme Regis.

THE MUSEUMS ASSOCIATION

ANNUAL CONFERENCE IN THE NETHERLANDS

THE sixty-second annual conference of the Museums Association was held jointly with De Museumdag in Amsterdam during June 27–30. Owing to the provisions of the Companies' Act, it was necessary to hold the annual general meeting in Britain, and this took place at University College, London, before delegates embarked for Holland. After welcoming some 320 delegates to the conference, the retiring president, Dr. F. S. Wallis (director of the City Museum, Bristol), gave an address on some of the recent activities of the Association. He outlined the negotiations with the Government concerning assistance to museums and more especially to private and trustee museums. The generous help of the United Kingdom Carnegie Trustees was acknowledged, and the great effect of their grants on museum work in Britain over the past twenty-six years was stressed. Dr. Wallis also referred to the value of the various regional federations, the courage of the governing bodies and curators of small museums, and the need for more committees to utilize the provisions of the Local Government Act of 1948 whereby financial assistance may be given to further local efforts of a cultural character.

In Amsterdam, delegates were joined by members of De Museumdag under their president, Dr. J. C. Ebbinge Wubben, and an official welcome was given by Mr. F. P. Th. Rohling on behalf of the Minister of Education, Arts and Sciences and the Burgomaster of Amsterdam. Afterwards, Prof. E. K. Waterhouse read a paper on "British Collections and Dutch Art", in which he reviewed the interrelationships of English and Dutch art with especial reference to the seventeenth-century artists. Another series of papers, by Dr. A. B. de Vries, Sir Philip Hendy, Dr. W. E. Swinton and Dr. D. B. Harden, discussed museum displays in the Netherlands and Britain since 1945. The conference was unusual in that papers were reduced to those already mentioned, and visits to museums and art galleries to study technical and display methods were increased to the maximum possible. During the period the institutions in Amsterdam, Rotterdam, The Hague, the National Park in Otterlo, Arnhem, Leyden, Gouda, Utrecht and Delft were visited. Hospitality was lavish on all occasions.

The president of the Museums Association for 1956–57 is Sir Philip Hendy (director of the National Gallery, London), and the next annual conference of the Association will be held in Bristol during July 8–12, 1957.

METEOROLOGICAL PROGRAMME OF THE INTERNATIONAL GEOPHYSICAL YEAR

A NUMBER of important articles on the meteorological programme for the International Geophysical Year, planned by the responsible Working Group of the World Meteorological Organization, with Prof. J. van Mieghem (Belgium) as chairman, are to be found in the January and April numbers of the Organization's *Bulletin*. The intention of the programme is to increase knowledge of the meteorology of the tropics and of the upper air in all latitudes. Priority has been given to problems which are fundamentally world-wide in character, so that their solution calls for effective international collaboration, and local or regional questions have not been considered.

In synoptic and dynamical meteorology the problems to be attacked are as follows: the redistribution on a planetary scale of momentum, absolute vorticity, energy and momentum, including frictional and topographical effects; exchange of heat and momentum between the atmosphere and oceans; flow patterns in low latitudes, including interaction between the southern and northern hemispheres; and the distribution of precipitation, especially over the oceans, in relation to large-scale flow patterns. The data collected in this work will assist also in such problems as meteorological influences on the Earth's rotation and the 'model' atmospheres used in numerical forecasting. In physical meteorology the subjects for observation are the distributions of ozone and water vapour, the heat balance of the atmosphere, and the large-scale features of the electric field in the atmosphere.

To ensure comparability of records, it is recommended that the instruments to be used should be compared with national standards and that the World Meteorological Organization should arrange a world-wide comparison of national radiosondes. It is recommended that special efforts be made by every country to make daily two radiosonde observations of pressure, temperature and humidity, and four of wind, up to at least 50 mb. (about 78,000 ft.) and, if possible, to attain the 10-mb. level (103,000 ft.). As regards radiation, the Working Group recommends that observations of the total short-wave radiation (that is, direct solar beam and short-wave sky radiation) should be made at stations in all types of climate to establish for all parts of the world the empirical formulæ for determining global radiation from sunshine duration. Besides this, measurements are recommended of the ultra-violet radiation, of the spectral distribution of energy in solar radiation, and of the long-wave radiation at the surface. The vertical distribution of ozone, so important in studies of ultra-violet radiation, is to be measured, in particular in the sub-tropical anticyclone belt.

For the study of meridional exchanges it is important to be able to draw good meridional cross-sections. The Group proposes that meridional sections shall be drawn from pole to pole along meridians 180°, 140° E., 75° E., 10° E. and 75° W. The first is especially important as giving an oceanic section almost from pole to pole. Minor sections are to be made along other meridians—for example, along the tropical parts of 30° E. and 110° E. It is hoped that aerological stations will be set up in sufficient numbers along these meridians to enable good cross-sections to be drawn.

As regards publication of meteorological data for the year, the World Meteorological Organization has taken the bold step of deciding to use microcards. National meteorological services are to be asked to send a copy of the observational records of their stations to the secretariat, where they will be printed on microcards and sold. A trial of the method is to be held in January 1957.

THE PHYSICAL SOCIETY

ANNUAL REPORT FOR 1955

AT the annual general meeting of the Physical Society, held in London at the offices of the Society on May 24, the reports of the council and of the honorary treasurer and the accounts and balance sheet for 1955 were presented and adopted, and the officers and council for 1956–57 were elected. The council reported that the balance of income over expenditure for the year under review was £1,220. However, it should be noted that expenditure for 1955 was more than £9,000 greater than for 1954, £4,000 of this increase being due to the greater expense of housing the thirty-ninth annual exhibition of scientific instruments and apparatus in the New Hall of the Horticultural Society instead of in the Imperial College of Science and Technology, London, where former exhibitions were held. Interest in the exhibition was as great as ever, the attendance exceeding eighteen thousand, and the increased expenditure on the exhibition was more than balanced by a gain in receipts from exhibitors.

The activities of the Society during the year included five science meetings in London; three joint colloquia with the Institute of Physics on electron physics in London; a three-day meeting at the Atomic Energy Research Establishment, Harwell, during March 31–April 2; and two-day meetings at the Universities of Liverpool and Cambridge during July 5–6 and December 13–14, respectively. A highly successful innovation was a Fellow's luncheon, which was held in London on April 25, the opening day of the annual exhibition. The eighteenth Thomas Young Oration was delivered by Dr. W. S. Stiles, who spoke on the basic data of colour matching and some related aspects of visual theory, and the thirty-ninth Guthrie Lecture by Prof. E. C. Stoner on magnetism in retrospect and prospect; both these lectures have been published in the "Year Book of the Physical Society, 1955". Dr. N. Kurti was the recipient of the tenth Holweck Medal of the Société Française de Physique and the Holweck Prize of the Physical Society; the presentation took place in Paris on May 26, when Dr. Kurti delivered the Holweck Discourse entitled "Le domaine des températures où regnent les spins" (*J. Phys. et le Rad.*, 17, 85; Feb. 1956). The thirty-second Duddell Medal was presented to Dr. R. Kompfner, who gave an address on travelling-wave tubes, and the eleventh Charles Vernon Boys Prize to Dr. J. W. Mitchell, who spoke on some of his work on photographic emulsions.

The Society continues to be represented on various committees and institutions, details of which are listed in the annual report, together with brief accounts of the activities of the four Groups of the Society—the Colour, Optical, Low Temperature and Acoustics Groups. The summer meetings of the Colour and Optical Groups were held at the Paint Research Station, Teddington, and University College, London, respectively, while the Low Temperature Group for its summer meeting paid a visit to the British Oxygen Company's air separation plant at Brinsworth, to the United Coke and Chemicals Company's hydrocarbon separation plant at Handsworth and to the Low Temperature Physics Laboratory at the University of Leeds.

In the section of the report dealing with publications, it is stated that, after a three years trial, the reprints scheme, whereby members and subscribers of the Society were able to purchase reprints of the papers published in the Society's *Proceedings*, has had to be discontinued. The general demand for the scheme was far too small to justify the large expense involved. Two conference reports, "Defects in Crystalline Solids", the report of a conference held in Bristol during 1954, and "The Physics of the Ionosphere", the report of a conference held in Cambridge during 1954, which were mentioned in the 1954 annual report, were published during 1955, and Volume 18 of "Reports on Progress in Physics", containing ten specialist articles, was issued in September. The flow of papers to the *Proceedings* increased during 1955. 265 papers and 115 research notes and letters to the editor were accepted for publication, as compared with 215 and 111 respectively in the previous year. Seventy-three manuscripts were either rejected or withdrawn. A new annual publication, commenced in the autumn of 1955, was "The Year Book of the Physical Society", containing the texts of the presidential address, the Guthrie Lecture and other special lectures to the Society, in addition to the annual report and accounts.

The officers and council of the Society for 1956–57 are as follows: *President*, Prof. N. F. Mott; *Vice-Presidents* (in addition to those who have filled the office of president), Dr. A. B. Wood, Prof. S. Devons, Prof. F. Llewellyn Jones and Prof. H. Jones; *Honorary Secretaries*, Dr. C. G. Wynne and Dr. H. H. Hopkins; *Honorary Foreign Secretary*, Prof. E. N. da C. Andrade; *Honorary Treasurer*, Mr. A. J. Philpot; *Honorary Librarian*, Dr. R. W. B. Pearse; *New Ordinary Members of Council*, Dr. V. E. Cosslett, Dr. D. Gabor and Mr. E. S. Shire.

THE DELI PALM

A RECENT issue of the *Journal of the West African Institute for Oil Palm Research* (No. 3, pp. 5–87; 1955) contains a number of articles of interest both to botanists and planters. It is an odd and sometimes disconcerting fact that a haze of obscurity overhangs the origin of so many of our major crops. This is particularly true of the Deli palm—a strain of *Elaeis guineensis* that has been cultivated with great success in the East—concerning which an important article is contributed by A. F. M. Broekmans and F. W. Toovey. Seed of the Deli palm was introduced into Nigeria at various times before the Second World War in the hope that it would afford a means both of increasing the yield of palm oil and of resisting some of the diseases to which the local West African oil palm is subject. It is reported that, over the first eight-year period, the local strains gave a much higher yield of fruit bunches than the Deli strains;

in fact, they outyielded them by about one-third. The superiority of the local strains seems to be increasing, as during the latter half of the period the difference in their favour was as much as two-thirds.

A comparison of the yields of the parent trees in Malaya with those of their progenies in the West African trial has shown an inverse relationship, the best trees in Malaya giving the poorest yielding progeny in Nigeria. Despite the generally poor showing of the Malayan Deli strains in the West African trial, one of them has done outstandingly well and is probably at least as good as, if not better than, the best Nigerian strain. The fruit and bunch composition of two leading strains is being studied in greater detail with the view of a breeding programme, and some of the preliminary data obtained are given. The authors conclude that the Deli palm is not well adapted to West African conditions, and, accordingly, the further introduction of Deli seed into West Africa for general planting is not recommended. There may, however, be certain already acclimatized strains as, for example, the Malayan Deli strain 19 × 65 in the aforementioned West African trial, which would repay exploitation for breeding purposes. Special characteristics of the Deli palm, such as disease resistance and dwarfness of growth habit, may also prove valuable.

AGE OF URANINITES FROM BLIND RIVER, ONTARIO

By R. K. WANLESS and R. J. TRAILL
Geological Survey of Canada, Ottawa

AS part of a continuing programme of the Geological Survey of Canada to date Canadian uranium deposits, two uraninite and three galena samples from the Blind River district of Ontario have been analysed chemically and by mass spectrometry. Ages of the uraninites have been determined using the lead : uranium, lead : thorium, and lead : lead ratios.

The Blind River region (Algoma district) in Ontario occupies a position of world importance as a uranium-producing area. In a period of two years following a prospecting rush in the area, six mines have been developed containing upwards of 150 million tons of ore at an average grade of between 2 and 2·5 lb. of U_3O_8 per ton[1].

Geological interest is widespread because of the similarities that exist between these deposits and the famous Witwatersrand deposits of South Africa. The mineralization, in each case, occurs in thin beds of quartz-pebble conglomerate which form part of a group of sediments overlying a complex assemblage of very old rocks. In both deposits, uraninite and gold have been reported in association with pyrite and minor amounts of other minerals, notably thucholite, monazite, zircon, rutile, galena, chalcopyrite and cobaltite. Brannerite is abundant locally in the Blind River deposits, but does not occur in the Witwatersrand conglomerates[2]. The origin of the Blind River mineralization is as controversial an issue as that of the Witwatersrand, and theories include the placer and hydrothermal concepts, and combinations of these.

Samples collected from the Pronto and Algom properties are described in Table 1. The galenas were concentrated from crushed drill-core samples using a Haultain superpanner. Microscopic examination revealed that the concentrates contained more than 95 per cent galena and less than 5 per cent pyrites and quartz. Radioactive assays indicated negligible radioactivity (less than 0·05 per cent U_3O_8 equivalent). Uraninite was concentrated from two high-grade hand specimens by superpanning and hand picking. The hand specimens were very similar macroscopically, and a mineragraphical study failed to reveal any differences in texture, grain size, and mode of occurrence of the uraninite. In both samples, the uraninite occurred as discrete angular grains, about 100 microns in diameter, in the pyritized matrix of quartz-pebble conglomerate. No other radioactive minerals were identified in the concentrates. Both concentrates contained about 10–15 per cent pyrites.

The isotopic abundances of the lead extracted from the uraninite and galena minerals were determined using a 90-degree Nier type mass spectrometer having a 10-in. radius of curvature. The sample was admitted to the instrument in the form of gaseous lead tetramethyl, and isotopic abundances were calculated from the tri-methyl ion currents in the 249–254 mass-range. The abundances quoted are the results of one or more mass spectrometric analyses, each consisting of at least ten repeat scans through the mass-range.

The lead isotope abundances are given in Table 1. Galena 1, from a non-radioactive zone, has a normal isotopic distribution whereas galenas 2 and 3, from

Table 1. ISOTOPIC ABUNDANCE OF LEAD FROM GALENA AND URANINITE

No.	Mineral	Location	^{204}Pb	^{206}Pb	^{207}Pb	^{208}Pb
1	Galena	Near Algom property, 1,500 ft. above ore zone in non-radioactive rocks	1·42 1·00	24·30 17·11	22·67 15·96	51·61* 36·35†
2	Galena	Algom property in quartz–pebble conglomerate in ore zone	1·06 1·00	36·04 34·00	15·99 15·08	46·92 44·26
3	Galena	Algom property in cross-fraction in ore conglomerate	0·76 1·00	45·21 59·49	14·14 18·61	39·89 52·49
4	Uraninite	Algom Quirke Lake, 4th level east face	0·10	86·15	8·19	5·56*

* Isotopic abundance in per cent. † Isotopic abundance relative to ^{204}Pb.

radioactive areas, have high radiogenic (lead-206, lead-207, and lead-208) lead abundances. Since a small lead-204 contribution was apparent in both uraninite samples a correction for common lead was required. Using the lead-204 abundance as an index of the amount of common lead present and the isotopic distribution of galena 1, a correction was applied to the uraninite abundances. This correction was based on the isotopic distribution of galena 1 for the following reasons: (1) galena 1 occurs in non-radioactive rocks adjacent to the Algom ore zone from which uraninite 4 was obtained; (2) the lead isotope abundances of galena 1 are of the same order of magnitude as those found for average ore lead of Precambrian age; (3) the best internal agreement between the ages determined from the lead : uranium, lead : thorium, and lead : lead ratios was obtained using galena 1 as a basis for correction.

The age determinations based on the lead-207 : lead-206, lead-207 : uranium-235, lead-206 : uranium-238, and lead-208 : thorium-232 ratios, listed in Table 3, indicate an average age of 1,300 million years for the Algom specimen and 600 million years for the Pronto uraninite. Since mineragraphical studies revealed no differences in the two hand specimens, and since both deposits occur in a pyritized formation which has been traced along strike for more than eighty miles, the determination of two distinct ages of uraninite mineralization is somewhat surprising. From the chemical values listed in Table 2 it is apparent that the lower age of the Pronto specimen results from the lower lead content, and that the uranium : thorium ratio for the two specimens is approximately the same. Loss of lead from pitchblendes (unpublished studies of the Geological Survey of Canada) has been held responsible for age variations in other deposits, and certainly the lead isotope abundances for galenas 2 and 3 (Table 1) illustrate the fact that radiogenic lead has been added to the original lead in these galenas. However, loss of lead from a radioactive sample produces a characteristic lead-207 : lead-206 > lead-207 : uranium-235 > lead-206 : uranium-238 > lead-208 : thorium-232 age distribution between the ages calculated from the various ratios. Such a distribution is not found for the Blind River uraninites reported here. This study indicates that the uranium and thorium contents of the two uraninites are similar, and that the Algom uraninite is much older than the Pronto uraninite. Further study may, however, reveal more than one age of mineralization in both deposits.

No.	Common lead correction	Age in millions of years			
		$^{207}Pb/^{206}Pb$	$^{207}Pb/^{235}U$	$^{206}Pb/^{238}U$	$^{208}Pb/^{232}Th$
4 (Algom)	Galena No. 1	1,170	1,300	1,400	1,265
5 (Pronto)	Galena No. 1	630	600	590	—

Preliminary mineralogical and isotopic studies indicate a complex history of mineralization in this region, and continuing studies based on selected, representative samples from all known radioactive occurrences are in progress. Considerable difficulty was experienced in obtaining sufficient material for analyses, and modifications to the experimental techniques are being carried out to permit isotopic determination on smaller samples.

We are indebted to the staffs of Algom and Pronto Uranium Mines, Ltd., for making the samples available for study. This communication is published by permission of the Acting Deputy Minister, Department of Mines and Technical Surveys, Ottawa.

VIVIPAROUS CAECILIANS AND AMPHIBIAN PHYLOGENY

By Dr. H. W. PARKER

British Museum (Natural History), London, S.W.7

THE classical investigations of the Sarasins and of Marcus and his pupils into the embryology and development of the oviparous caecilians *Ichthyophis* and *Hypogeophis* have diverted attention from the fact that many of these little-known amphibians bear living young. This was first established as long ago as 1874, when Peters[1] recorded the occurrence of fœtuses in the oviducts of the species now known as *Typhlonectes compressicauda*. Since then, fœtuses have been reported in five other genera; but no one has determined whether the animals are merely ovoviviparous, retaining the eggs in the oviduct until ready to hatch, or whether nutritional material (embryotrophe) additional to the yolk of the egg is supplied by the mother.

Pregnant females of several species of four genera have been examined, and it is clear that the included yolk of each egg suffices for only a small part of the pre-natal growth and development. Several stages of pregnancy and the neonatal condition of *Geotrypetes* have been seen, and the sequence of events they reveal is as follows. The eggs are large, yolky and enclosed in a tough vitelline sphere just like the eggs of oviparous species. They are about 4 mm. in diameter and initially they are passed to the hinder end of the oviducts, where they lie in single file in contact with one another. Development proceeds inside the vitelline membrane until the fœtus is about 25 mm. long (mother 265 mm.), when hatching occurs. Until now the fœtus has been coiled, figure-of-eight fashion, over its yolk sac and has possessed long plumose external gills, three on each side with a short common stem. At the hatching stage the yolk mass has almost disappeared and the gills are in process of resorption. After rupturing the vitelline sphere, the embryos migrate in the oviduct and space themselves out equidistantly from one another throughout its length. They now lie fully extended, and by the time they have reached a length of 38 mm. the external gills have completely disappeared. Growth *in utero* continues and neo-natal specimens average 75 mm. in length. There is thus

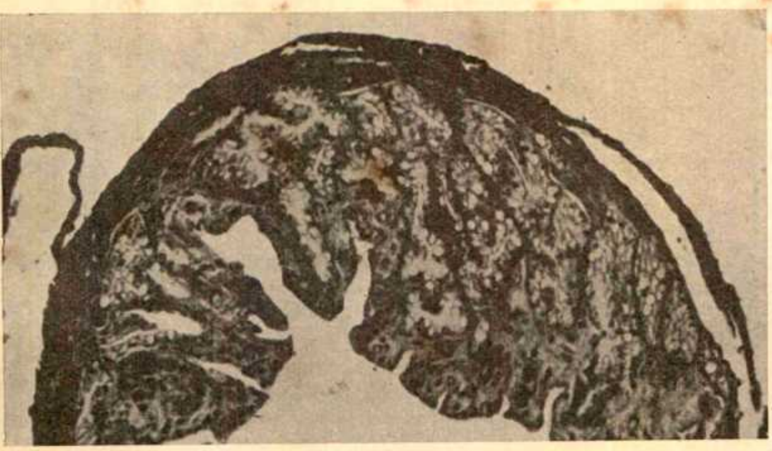

Fig. 1. *Schistometopum thomense.* Transverse section of anterior portion of pregnant oviduct, showing racemose glands and oil vacuoles. (× 90)

a 27-fold increase in mass after the initial yolk material is approaching exhaustion, and there must be some additional supply of nutritive material.

This general pattern may prove to be common to all the viviparous species. In the allied genus *Schistometopum*, fœtuses of 32–36 mm. have hatched and migrated and have no visible signs of yolk; their gills are small and asymmetrical and are presumably being resorbed. Fœtuses of 88–90 mm. (mother 257 mm.) are gill-less. Among the South American genera, gills (which are single and plate-like) are present in fœtuses of 59 and 62 mm. (*Chthonerpeton*) but wanting at a length of 110–120 mm. (*Gymnopis*: mother 405 mm.).

The mode of nutrition of the later fœtal stages is, as in many other anamniotes (cf. Matthews[2]), by means of 'uterine milk' ingested through the mouth. Many of the fœtuses examined had full stomachs, the material being mostly an amorphous non-cellular mass, but often containing a considerable amount of cellular debris and sometimes some recognizable erythrocytes. In the only fresh material seen (*Schistometopum*) the stomachs of the 88–90 mm. fœtuses contained a thick white creamy material consisting mainly of an emulsion of fat droplets, together with disorganized cellular material. This was clearly derived from the walls of the oviduct, which are richly provided with compound racemose glands lined by deep columnar epithelial cells the cytoplasm of which contains large oil globules (Fig. 1). It was also observed that the gall bladder in these fœtuses was relatively large and the contents of the hind gut were deeply coloured with bile.

The epithelium lining the lumen of the oviduct is highly vascular, with numerous capillaries lying within a few microns of the surface and thus fulfilling requirements for gaseous exchange. Correspondingly, the fœtal epidermis is nowhere more than two cells thick and is equally richly supplied with capillary blood vessels. The needs of the fœtus after loss of the gills are thus met by cutaneous respiration, but this must introduce a new problem for the animal. Such a delicate and highly vascular epidermis would be quite unsuitable for a burrowing life after birth. This difficulty appears to be overcome by sloughing the fœtal corneal layer immediately after parturition, coupled with a resting phase during which a new, thicker and tougher stratum corneum is proliferated. Newly born specimens of *Geotrypetes* have, in fact, been collected with their stomachs packed with their own sloughed cuticle one cell thick[3].

The caecilians thus exhibit no very novel departures from the method of viviparity occurring elsewhere among the anamniotes, but they do possess a feature that appears to be unique. There is a deciduous fœtal dentition. In all the fœtuses examined, the teeth are unlike those of the adult, both structurally and in arrangement. The teeth consist of two parts: a tubular pedicel and a crown with a hinged joint connecting the two (Figs. 2 and 4). The crown varies in shape from species to species and genus to genus; it may be spoon-shaped, with or without a single terminal cusp, spatulate and multicuspid or simple and recurved.

The teeth are arranged in multiple rows arranged quincuncially to produce a rasp-like structure, the number of rows varying on the different dentigerous elements of the skull and from species to species. (It is expected that a joint paper by the author and the late Prof. E. R. Dunn describing the various conditions in detail will be published soon.) The highest number of rows observed occurs on the nasopremaxillæ of *Chthonerpeton petersi*, where there are at least twelve; more usually, however, there are three or four rows (Fig. 2). The pedicels of the anterior rows are fused (Fig. 3) and the resulting plate is attached to the underlying dermal bone. This type of dentition has been found in fœtuses of every viviparous species examined. Nothing resembling it has been found in any free-living larva or in

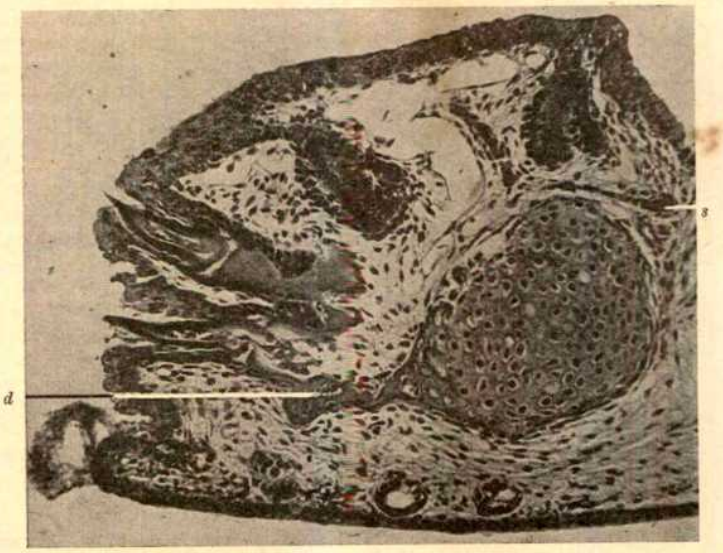

Fig. 2. *Chthonerpeton viviparum.* Paramedian section of fœtal lower jaw showing rows of hinged, pedicellate teeth associated with the dentary (*d*) and splenial (*s*) bones. (× 125)

the intra-capsular embryos of any species in six genera of oviparous caecilians; in these the teeth are like those of the adult.

The fœtal teeth are replaced by bicuspid, adult-type, teeth just before or just after parturition. In a very late (145 mm.) fœtus of *Gymnopis mexicanus mexicanus*, teeth are of the adult type, although younger fœtuses of the same subspecies have a typical rasp; on the other hand, newly born examples of *Geotrypetes seraphini* still have the fœtal rasp, although adult bicuspid teeth are also present but not attached to the bones.

Although there is a clear association between a special fœtal mode of nutrition and a special fœtal dentition, the latter can scarcely be an adaptation for the former. Apart from the apparent unsuitability of such a formidable rasp-like armament for ingesting milk, it is incredible that such an adaptation would have been developed more than once. So, all the species possessing it would represent a close phylogenetic assemblage. Yet any such taxonomic grouping cuts right across the systematic arrangements based on all other characters. For example, in American genera the gills are single and plate-like, but in the African forms they are triaxial and plumose; some genera are markedly zygokrotaphic, others slightly so, and one is completely stegokrotaphic. The only alternative explanation is that the fœtal dentition is an ancestral character that can persist only under conditions where teeth are not required and that has been suppressed as ineffective wherever a raptorial dentition is needed.

If this is indeed the explanation, it is not unreasonable to expect to find some traces of the ancestral condition elsewhere among the Amphibia, and this expectation is fulfilled. The amphibian tooth, both Urodele and Salientian, has two parts, pedicel and crown, separated, especially when young, by a washer of uncalcified tissue; these two parts, though not connected by a hinge, are clearly homologous with the two parts of the caecilian fœtal tooth. Further, the pedicels of Urodele and Salientian teeth fuse when they are in contact. Again, there are many instances, especially among the Urodela, of the teeth being arranged in multiple rows, and this occurs most frequently among the permanently neotenic "Perennibranchiates". Examples are *Siren* with several rows on the vomers, palatines and splenials, and the axolotl, which manifests "The ichthyic character of rasp-like teeth, aggregated in numerous series . . . upon the palatal region of the mouth and upon the splenial or opercular element of the lower jaw" (Owen[4]). The Urodela also show a tendency towards multiplicity of teeth in the larval stage and a reduction at metamorphosis. Throughout the Salamandridae, for example, larvæ have a splenial with several rows of teeth that are all lost in the adult, and multiple rows on the vomer are reduced to one in *Salamandra* and *Amblystoma*. Newly born larvæ of *Salamandra salamandra* and uterine larvæ of *S. atra* have four rows of teeth on the dentary and, although it has been claimed that these represent merely a single 'functional' row with successional replacements, they are arranged quincuncially and the two outermost are 'functional' in the sense that both are fused to the bone.

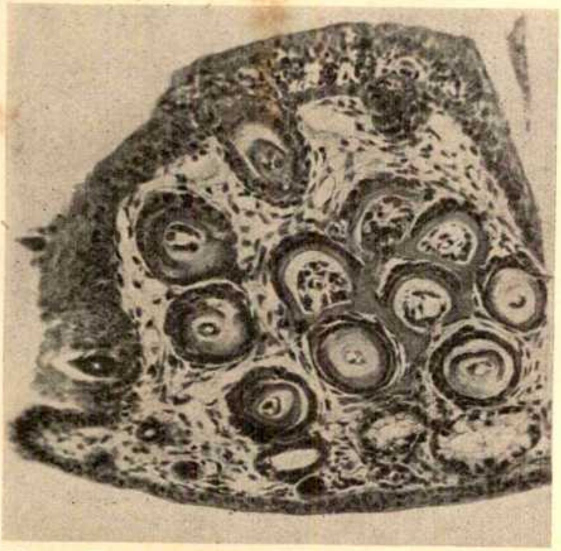

Fig. 3. *Chthonerpeton viviparum*. Transverse section of fœtal lower jaw, anterior to the symphysis, showing dental pedicels, some fused. (× 125)

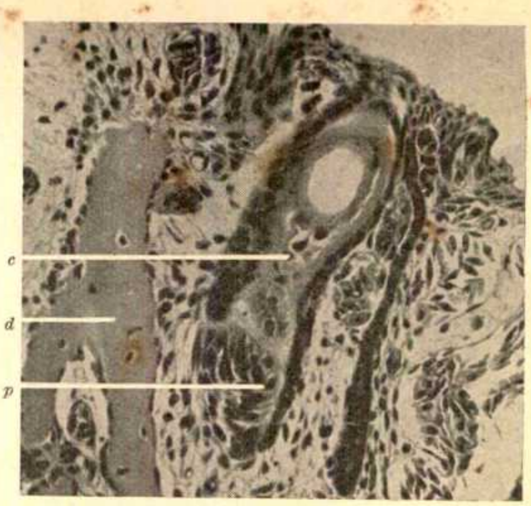

Fig. 4. *Schistometopum thomense*. Vertical section through a developing spoon-shaped fœtal tooth of the dentary series. The pedicel (*p*) is developing in association with the crown (*c*) and not as an outgrowth of the dentary (*d*). (× 200)

It seems, therefore, that the ancestor of the recent Amphibia possessed numerous rows of hinged teeth on all dentigerous bones. Owen characterizes a rasp-like dentition as "ichthyic"; but however that may be, there can be little doubt that this ancestral dentition was associated with a different method of feeding, and probably a different, perhaps vegetarian, diet. The ancestral dentition persists to the greatest extent in the most primitive group, the Gymnophiona, when circumstances permit, and to a lesser extent in some of the Urodela. In this latter group, however, as in those caecilians with a free larval life, their predaceous, carnivorous habits have required complete, or almost complete, suppression of the multiple, hinged, teeth and their substitution by single rows of rigid teeth modified from the original pattern by elimination of the hinge and simplification of the crown. The horny dentition of the Anuran tadpole must be accounted a secondary feature developed in association with a further change in larval feeding habits.

DIMORPHISM IN THE PORTUGUESE MAN-OF-WAR

By A. H. WOODCOCK

Woods Hole Oceanographic Institution, Mass.

THE interesting problems of the sailing of *Physalia* have been revived by Totton and Mackie[1] and Fontaine[2]. Since the publication of my observations on the predominance of the left-sailing *Physalia* in the North Atlantic[3], I have had numerous opportunities to observe them in various parts of the world. These observations continue to show that North Atlantic animals are predominantly right-handed. Observations of *Physalia* in the North Pacific show similar results. Unfortunately, the southern hemisphere data are not yet extensive enough to test fairly my original suggestion that most of the animals on the southern seas may be mirror images of those in the northern hemisphere.

The purpose of this communication is to present and discuss these additional observations (see Table 1) and to discuss further the suggestions of Wilson[4] and of Totton and Mackie[1] concerning the role of wind direction in altering the 'landfall' possibilities of the two differently-sailing *Physalia*.

First, it should be pointed out that the original observations showing the dominance of the right-handed (left-sailing) *Physalia* in the northern hemisphere were made on the open sea. These data are not subject to the local wind-direction errors of beach observations, a fact which Totton and Mackie seem to have overlooked. Beached animals do, however, show a clear and similar dominance of right-handedness in the northern hemisphere when the local winds are nearly directly on shore. For example, compare observations 1, 2 and 3 in Table 1.

The greater number of the right-handed animals on the open sea does not necessarily indicate that this condition existed at the time the animals changed from the larval form. However, the numerical dominance of the right-handed animals, which was evident among the smallest of the *Physalia* found on a Florida beach (see Fig. 1 and Table 1), suggests that this dominance is present at the start.

These Florida observations, and many of those in Hawaii as well, indicate that the selective processes favouring the left-sailing animals begin very early in the life of the animal, if one supposes, with Totton and Mackie, "that in each brood of *Physalia* the two forms are produced in rough equality . . .".

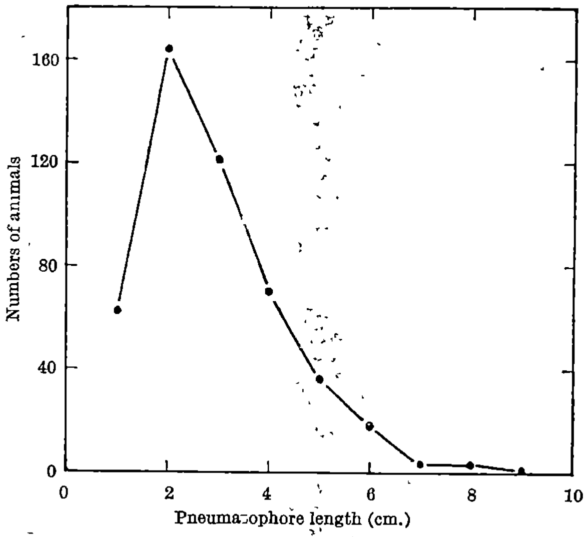

Fig. 1. A representative distribution of pneumatophore length among the *Physalia* seen during March, April and May 1944 on Ft. Pierce Beach, Florida. See Table 1 for total numbers

I have also measured roughly the sailing speed of a left-sailing North Atlantic *Physalia*, its angle of motion relative to the wind, and the approximate rate of down-wind drift of the upper 0·5 cm. of surface water. My results are about the same as those of Totton and Mackie, and are illustrated in Fig. 2.

Note in this figure that the number of animals which can land in unit time and on a unit length of beach (H) depends upon the angular relationship between their sailing-course line (for example, line BC) and the beach line (H). These lines control the angle α, and the length of line A. Thus the sine of the angle equals the ratio of the total possible landings on a section of beach (H) to the observed landings. This relationship is expressed in the following equation, and may be applied to all *Physalia* where α is known.

$$N_c = \frac{1}{\sin\alpha} N \qquad (1)$$

Table 1. OBSERVATIONS OF THE NUMBER OF RIGHT-HANDED (LEFT-SAILING) AND LEFT-HANDED (RIGHT-SAILING) *Physalia* SEEN ON THE SURFACE OF THE OPEN SEA AND ON VARIOUS SHORES. THE 'AT SEA' DATA INCLUDE THE ORIGINAL OBSERVATIONS FROM REF. 3

Data No.	Name	No. observed		Date	Location	Ratio of right-sailers to left-sailers	Average on-shore wind angle*	Position		Place name
		Right-handed	Left-handed					Lat.	Long.	
1	*Physalia physalis* L.	159	3	1939–45	at sea	0·02	—	25°–40° N.	46°–80° W.	North Atlantic
2	*Physalia physalis* L.	344	9	1942	at sea	0·03	—	26°–28° N.	84°–89° W.	Gulf of Mexico

* The 'average on-shore wind angle' is measured in a counter-clockwise direction from a line parallel to the beach.
† From ref. 5.

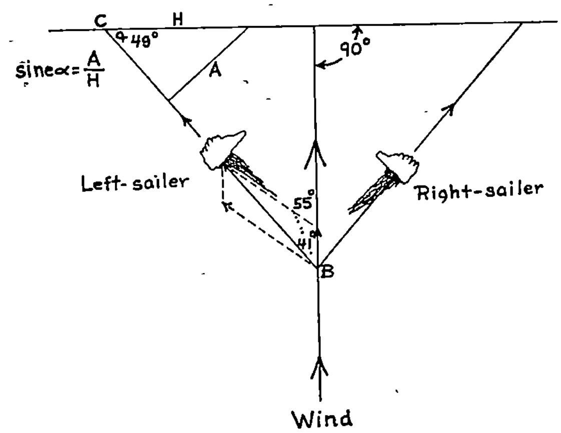

Fig. 2. Average sailing performance of a right-handed, left-sailing *Physalia physalis*, and further suggestions about effects of wind direction upon the number which will sail on to a shore (see text). A right-sailer is also shown in order to emphasize its markedly different sailing course in response to the same wind. Average speed of topmost 0·5 cm. of water = 9 cm. sec.$^{-1}$; average speed of wind = 680 cm. sec.$^{-1}$; average speed of *Physalia* = 26 cm. sec.$^{-1}$; pneumatophore length 17 cm., height 7 cm.

where N_c is the maximum possible number of arrivals in unit time and length of beach, and N is observed number of arrivals.

From Fig. 2 and the above equation it can be seen that the number of arrivals of the two forms of *Physalia* on a beach will represent the relative distribution on the sea only when the wind angle is 90° and the sailing angles α are equal.

The very small *Physalia*, such as most of those observed in Florida (see Table 1 and Fig. 1), sail much more slowly than the large *Physalia*. Their sailing course, assuming the same angular relationship to the wind as the large animal, would tend, therefore, to approach the shore at an angle which more nearly equalled that of the wind. For example, an animal sailing at one-fourth speed would follow a course from B, Fig. 2, shown by the dotted line. This may explain why the ratio of the right to the left-sailers on the Florida beach (see Table 1, observation 4) was so similar to this ratio among those observed on the open sea, despite the occasional obliquity of the wind.

On Lanikai Beach, Oahu, Hawaii, the north-east trade wind was almost always blowing from the sea and nearly normal to the beach. Hence the relative number of the two types of animals observed on this beach, as given in Table 1, observation 3, should represent their relative distribution on the open sea. During one exceptional period of several days, however, southerly or 'Kona' winds occurred, producing off-shore winds on the lee side of Oahu which carried the normal *Physalia* population far out to sea. Thus the lee side of the island became a 'shadow zone' for right-sailers (Fig. 3). For a period of about a day after the shift from southerly winds to the normal 'trades' occurred, only left-sailing *Physalia* were seen on the beach (see observation 5, Table 1). This result is explicable as illustrated in Fig. 3, the Kaiwi Channel producing a local separation of the two forms. (For convenience, equal numbers of lines are shown representing the differing sailing courses of the two forms during south-south-west winds. It is not intended to imply that an equality of number of the two forms exists at sea.) The first left-sailing *Physalia* to reach Lanikai beach after the wind shift to the north-east would presumably come from point A, while the first right-sailer would sail a greater distance from point B. Assuming the same sailing speed and sailing direction relative to the wind as that of the Atlantic *Physalia* (Fig. 2), the difference in the arrival time of *Physalia* from these two points would be about thirteen hours and may account for the observed complete dominance of the left-sailers among the first arrivals on the beach after the wind shift.

Observation 6, in Table 1, was made on the southern end of Deewhy Beach, Sydney, and seems to support the idea that most of the southern hemisphere animals sail to the right of the wind. On the only day when I was free to walk on the beach and to observe the stranded *Physalia*, the average wind angle was about 45° to the general trend of the irregular coast line of this region. According to equation (1), very few right-sailers should have been found on Deewhy Beach, since the angle α for the right-sailers would in this case become 4°, and the sine about 0·07. Actually, about one-half of the animals seen were right-sailers. These Deewhy Beach observations, when 'corrected' for the effects of the average sailing angle on the number of the right-sailers arriving on the beach, suggest a dominance of this form on the open sea of about ten to one of the left-sailers. This ratio agrees roughly with that among the southern hemisphere museum specimens discussed in the previous paper[3].

The above 'correction' is open to the serious objection that it is made using the sailing characteristics of the somewhat larger North Atlantic *Physalia*, which are given on Fig. 2. Also, in common with all beach observations of stranded animals, there are the added questions about the effects of coastal currents, and of changes in wind direction which may have occurred after they sailed ashore and before I arrived at the beach to observe them. It is hoped that someone will soon test these rather unsatisfactory southern hemisphere data by direct observation on the open sea in the Sydney region or elsewhere.

If further work proves the existence of a world-wide difference of *Physalia* form and sailing performance in the two hemispheres, we shall wish to know to what extent various physical factors may have produced this difference. Will such dominance of one form in each hemisphere be due to ecological factors acting selectively on each generation, to established genetic differences, or perhaps to 'tack' changes

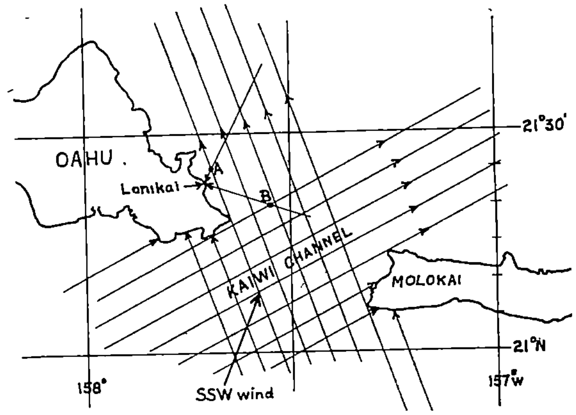

Fig. 3. Assumed separation of left-sailing and right-sailing *Physalia* in passing through Kaiwi Channel before a south-south-west wind. Note that the lee side of the islands is, in varying degree, a 'shadow zone' for either one or both forms. Following a wind shift to the normal east-north-east trades, the first animals of the two forms arriving on Lanikai Beach would sail different distances, along the new course lines shown, from points approximating intersections A and B

caused by migration of the tentacles on the pneumatophore? The answers to these questions will be interesting and perhaps useful in further studies.

My earlier proposal concerning a possible selective influence of small-scale wind-induced eddy motions in the surface waters[3] still seems reasonable to me. Larger-scale wind and water motions may be important, however. It is worth noting here that left-sailing *Physalia* in the average anti-cyclonic wind systems of the North Atlantic and the North Pacific[6] will move away from the centres of the systems, and often in the direction of coastal waters. The average wind systems of the oceans of the southern hemisphere tend to be cyclonic[6]. In cyclonic wind systems a right-sailer will also tend to sail away from the centres of the systems and in some cases toward coastal areas.

I am convinced that there is much that oceanographers can learn about the surface waters of the seas from detailed studies of the sailing of *Physalia*.

I am indebted to my young son, John B. Woodcock, for his enthusiastic help in collecting observations in Hawaii.

STIMULATION OF COLEOPTILE- AND ROOT-GROWTH BY EXTRACTS OF MAIZE

By S. HOUSLEY*, A. BOOTH and I. D. J. PHILLIPS

Botany Department, University of Manchester

PAPER chromatography of the acidic ether-soluble material in plant extracts has revealed the presence of several growth-promoting and -inhibiting substances in a range of plant material[1] including roots and shoots[2,3]. One promoter, termed accelerator-α, has been shown[3,4] to enhance the growth of both roots and coleoptiles above that of a control at certain concentrations, yielding in the case of roots a characteristically shaped activity curve (similar to Fig. 3). Accelerator-α, an ether-soluble substance[5], possibly does not normally occur in plants[6]; but is thought to be formed during the preparation of plant extracts for chromatography from other compounds which occur in the aqueous ether-insoluble portion of extracts[5]. With tomato roots[6] this aqueous material, after chromatography on paper with ammoniacal n-butanol and bioassay with coleoptile sections, gives three zones of growth promotion. At least two of these zones, if eluted from the paper individually and then rechromatographed in the same solvent system on a new paper, result in chromatograms with the same pattern of growth promotion, showing that some of the active substances on the chromatograms may be converted readily from one to another. The present work reports the occurrence of similar compounds in maize and describes their effect upon the growth of cress roots.

Coleoptiles (703 gm.) and roots of four-day old maize seedlings (a dent-type derivative from Rhodesian 'White Salisbury' commercially termed 'African Giant Horse Tooth Hybrid') grown in the dark at 25° C. were quickly frozen, coarsely comminuted, and extracted separately in 1·5 l. ether at −5° C. and natural pH (approximately 5·5) for 4 hr. Protein was precipitated from the aqueous ether-insoluble fraction with ethanol (2 vol. absolute : 1 vol. aqueous fraction) and centrifuged off, and the alcoholic remainder distilled under reduced pressure to an aqueous syrup (34·7 gm. coleoptile extract) at a bath temperature of 40° C. The extracts were stored at −15° C. Paper chromatography was carried out in n-butanol saturated with $1 \cdot 5\,N$ ammonia; details of the chromatographic technique and of chromogenic spray reagents are described elsewhere[5], except for the Salkowski reagent (1 ml. 0·5 M ferric chloride + 50 ml. 35 per cent perchloric acid). The methods of bioassay with coleoptile sections of oats (Victory)[7] and roots of cress[5,8] have been reported previously. In the cress test, test solutions were pipetted on to filter paper in Petri dishes and were not incorporated into agar as previously described[5]. All means are derived from ten replicates, except in Figs. 3 and 4, where the number is shown above the standard error or mean.

Chromatography of the coleoptile aqueous syrup (0·33 gm., equivalent to 7·2 gm. fresh weight, on an 18 cm. starting line) in n-butanol/ammonia usually results in a histogram with four peaks (Fig. 1); but there may be less (Fig. 2, 0·74 gm. syrup on a 19 cm. line); similar results are obtained with corresponding extracts of roots. Although activity in the roots and coleoptiles is rather low compared with tomato roots[6], it is consistently present. Unpublished work by Mr. G. Britton in these laboratories has shown that these zones of growth promotion behave in a manner similar to those of tomato roots[6] when they are rechromatographed.

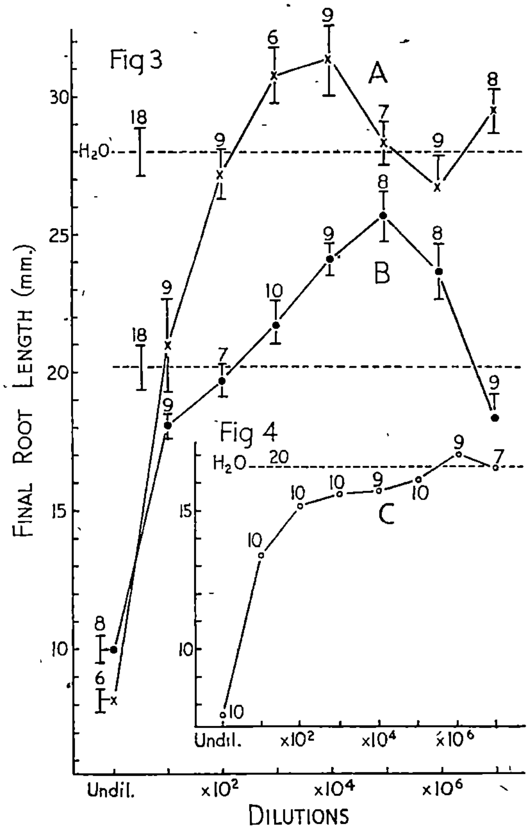
Results obtained with chromogenic sprays on chromatograms of coleoptile extracts are shown in Fig. 1. With roots, the chromogenic pattern with the same sprays was very similar except that the R_F values were smaller, and p-dimethylaminobenzaldehyde gave a more intense purple reaction (R_F 0·13–0·21) and ferric chloride/perchloric acid a yellow reaction in the same zone: in this respect it is of interest that R_F values may be influenced considerably by the viscosity of the aqueous syrup and the quantity loaded on a chromatogram. No evidence was obtained of the presence of 3-indolylacetic acid on any chromatogram. Ether-soluble material of the coleoptile and root extracts was also chromatographed, bioassayed and examined with chromogenic sprays; again, no evidence of the presence of 3-indolylacetic acid was obtained.

To examine the effect of growth promoters in the aqueous ether-insoluble fraction on the growth of roots, chromatograms were prepared in a manner similar to that used for Fig. 1 and a longitudinal strip bioassayed with coleoptile sections. The remainder was stored dry in the dark at −15° C. for 24–48 hr. until the R_F values of the active zones were known; these, between the limits of R_F 0 and 0·5, were then cut out of the stored portion, eluted with water and tested on cress roots. In some tests activity curves similar to *A* and *B* (Fig. 3) were obtained, whereas in others curves similar to *C* (Fig. 4) were given. Other data of interest were obtained when certain zones of a maize coleoptile chromatogram (Fig. 2) were tested on cress roots before the result of the corresponding oat assay was known. It is seen that in addition to the active zone *B*, the inactive zone *A* has stimulated root growth above a water control (Fig. 3, *B* and *A* respectively). Two other zones of the chromatogram were also tested (R_F 0·6–0·7 and 0·8–0·9); both gave curves similar to *C* in Fig. 4.

---

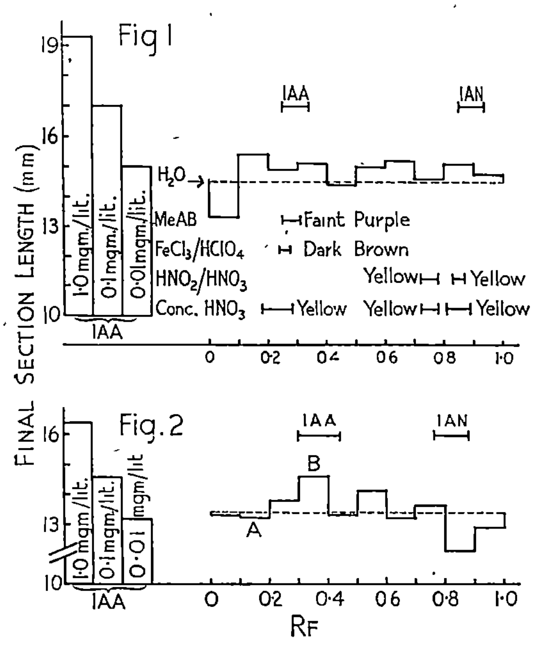
* Present address: Horticultural Department, Colworth House, Sharnbrook, Bedford.

To account for these results, in which enhanced coleoptile- and root-growth may occur in the same zone or in different zones of chromatograms, it may be suggested that there were two chemically distinct types of growth-inducing substances present in the extracts, one auxin-like[9] inducing coleoptile-growth and the other, possibly hormonal[9] but not auxin-like, inducing root-growth. On the other hand, there may be a closer chemical relationship between these substances, and conversion from one to the other has to occur before enhanced root-growth can be obtained. The present data, including those of zone *A* in Fig. 2 in which conversion could have occurred before chromatography was carried out, may be interpreted equally well by either hypothesis and further work is required before a firmer opinion can be expressed.



Figs 3 and 4 Activity curves of cress roots (initial length 5 mm.). Curves *A* and *B* were obtained from eluates taken from zones *A* and *B* of the chromatogram of Fig. 2. Curve *C* was obtained from the eluate of a zone of a maize root chromatogram (not shown) corresponding to R_F 0 1–0 2 in Fig 1

The inability to detect free 3-indolylacetic acid in coleoptiles and roots of maize seedlings confirms other unpublished work carried out at Manchester on maize in which no indolylacetic acid has been found in the plant except in the fruit. This absence of indolylacetic acid is of particular interest in growth studies, for it has been long held that it is the sole or principal auxin in plants and that in roots it is present at supra-optimal concentrations. However, from the present studies and others in progress at Manchester, we have been led to question these views. On chromatograms of aqueous ether-insoluble extracts and on many chromatograms of ether-soluble materials, active zones of coleoptile elongation cannot be systematically associated with the chromogenic reactions given by those reagents generally used for indole detection. This and other evidence available at the present time suggests that in the plant there are other hormonal substances besides 3-indolylacetic acid controlling growth, the chemical nature of which may be non-indole.



Figs 1 and 2. Chromatography in *n*-butanol/ammonia of the aqueous ether-insoluble fraction of extracts of maize coleoptiles. The R_F of marker spots of 3-indolylacetic acid (IAA) and 3-indolylacetonitrile (IAN), and the response of oat coleoptile sections (initial length 10 mm.) in solutions of IAA are shown. MeAB = *p*-dimethylaminobenzaldehyde

We thank Prof. S. C. Harland for generous facilities in the Department of Botany, and Drs. P. F. Wareing and R. Pecket and Mr. J. Hannay for constructive criticism and valuable discussion. The work was supported by grants to two of us (A. B. and I. D. J. P.) by the Department of Scientific and Industrial Research.

Drift Experiments with Radioactive Pebbles

An experiment on the detection of movement of pebbles on the sea bed was carried out off Scolt Head Island in Norfolk during April and May 1956. Pebbles marked radioactively were used for this purpose. It is believed that it is the first time that such a method has been used in Britain to trace pebbles.

In each pebble, a hole ½ in. deep and ⅛ in. diameter was made. It was found that local flint from the beach was very difficult to drill, and a compromise had to be made by using pebbles of Permian Sandstone, with a few flints only, and also a number of pebbles made of cement. The pebbles averaged about 2 in. in major diameter and were all rounded. The specific gravity of the pebbles averaged 2·4, which is about 0·2 less than that of flint. In all, some twelve hundred were used.

The radioactive tracer used was barium-140, an isotope with a half-life of 12 days, which decays by beta-emission and low-energy gamma-radiation into lanthanum-140 (half-life 40 hr.). The lanthanum emits a series of gamma-rays of which the principal has an energy of 1·6 MeV., and it was these gamma-rays which were used for detection under water.

For loading the pebbles, pure barium-140 was used to avoid health hazard from the gamma-rays. The lanthanum-140 activity, which was negligible during loading, then built up to a maximum in about five days, after which it was almost in equilibrium with the barium-140 and decayed with an effective half-life of 12 days. About 15 microcuries of barium-140 was adsorbed to each of twelve hundred resin particles, and one of these was placed in each pebble and sealed with a resin-based adhesive.

In this experiment, three Geiger counter tubes with a sensitive length of 60 cm. were enclosed in a brass cylinder of 1 metre in length. The cylinder was mounted on a heavy metal sledge. The sledge was towed along the sea bed over an area of several hundred yards around the dumping position on each search. In the boat was a rate-meter, connected to the tubes in the cylinder by a multicore cable. The detector was capable of 'finding' a pebble at a distance of about twelve inches under water.

On April 5 the pebbles were all dumped at the same moment from a boat at a point some 500 yd. seaward from normal high-water mark off Scolt Head, in water varying in depth between 12 ft. and 25 ft., depending on the state of the tide. Throughout most of the time of the experiment the depth of water over the main dump of the pebbles was of the order of 16–20 ft. The shallowest depth of 12 ft. was only recorded at low-water springs and the greatest depth at high-water springs. The floor on which the pebbles were to be dumped was hard and consisted of shingle and sand. The place had been marked with a buoy which was placed 20 yd. farther seawards of the dump so that when detecting operations were carried out the buoy ropes should not foul the detecting apparatus. The position of the buoy was fixed by intersection from angles measured by theodolite and sextant from three fixed points on the island. The position of the stones was fixed by sextant angles from the boat to those points on the land. The weather at the time the pebbles were dumped was squally, and the following night there was a wind reaching force 5–6. It was impossible to make any further observations until April 8. On that day, clear records were found of some of the pebbles having moved southwards and a little west up to a distance of 200 ft. Further searches were made on April 9, 12, 20 and 23 and on May 5 and 15. The results obtained on all these dates were generally consistent and showed clearly that a number of pebbles had moved and continued to move very slowly in a direction slightly west of south, that is, inshore. The maximum movement was of the order of 260 ft. In addition, observations made on May 15 showed that some pebbles had also moved north and west, one definite record being found about 450 ft. north-west of the original dump. It may have been that this north-westerly movement had occurred previously, and was only found on May 15 ; but this seems unlikely since the area had been swept over on each search. It should be appreciated that the detecting apparatus sweeps a band only one metre wide, and therefore a considerable time is needed to sweep even a small area of sea bed, and it is impossible to guarantee that every square yard of a given area has been searched.

Nevertheless, the results show that in ordinary weather, with a few squalls but no true storms, pebbles can be moved along the sea floor. Waves during this period are not likely to have exceeded 3 ft. in height. The flood current in this part of Norfolk flows west, and the ebb to the east. The maximum speed of the flood at springs is about 2½ ft./sec. It seems unlikely that the current itself can move pebbles of this sort; but it might certainly work in with wave action and help to do so.

This experiment was designed to work out a technique for the use of radioactive tracers in determining underwater movement of coarser beach material. If the method can be perfected, it will give a very important aid to coastal physiographical study.

Radiation-induced Changes in Reactivity of Bovine Fibrinogen

The acute effects of total body irradiation on mammalian hæmostasis are now well established[1]. Information concerning direct effects on individual clotting components is meagre, and in the case of fibrinogen is confined to observations following the application of doses of X-rays of such high magnitude as to have no practical significance in the field of mammalian radiation damage[2,3]. The present study of fibrinogen is therefore concerned with the direct influence of low doses of irradiation.

Purified bovine fibrinogen (lot No. 55199) was generously supplied by Dr. E. C. Loomis, of Parke, Davis and Co., and was shown to contain 90–93 per cent clottable protein. Solutions of this fibrinogen (3 mgm./ml.) in 0·15 *M* sodium chloride buffered

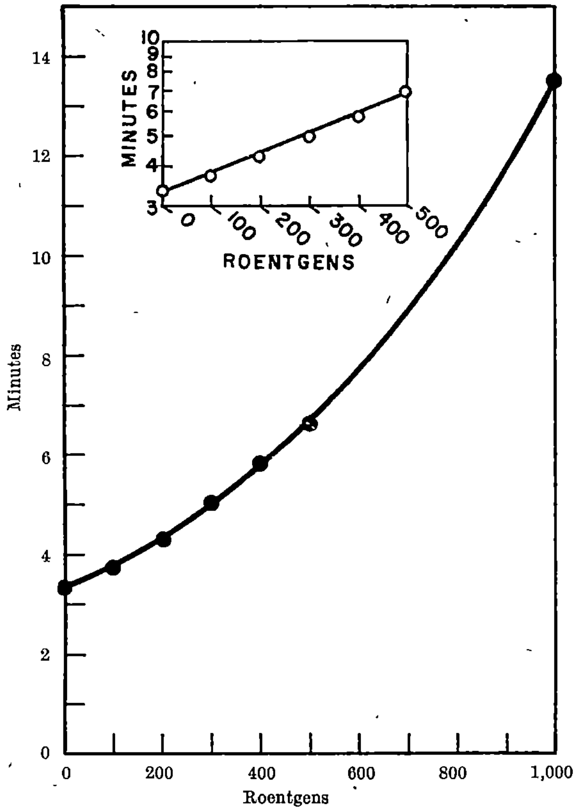

Fig. 1. Firm-gel clotting-time of irradiated bovine fibrinogen. (Inset: semi-logarithmic plot of data)

with imidazole at pH 7·4 were exposed to single X-ray doses, and the firm-gel time of a 0·3-ml. sample upon the addition of 0·05 ml. containing 1/16 unit of purified bovine thrombin was determined at 37·5° C. As Fig. 1 shows, the clotting time was increased with increasing X-ray dosage in the range of 100–500 r. and above. A similar relationship was obtained in the range of 25–100 r. The clotting delay was found to be independent of the fibrinogen concentration from 1 mgm./ml. to 5 mgm./ml., but was proportional to the thrombin concentration in the range of 0·063–0·5 units, at which point the clotting delay was abolished.

The clotting delay was accompanied by an alteration of the firm-gel characteristics. The rate of solution in 5 *M* urea of fibrin clots obtained from irradiated fibrinogen was accelerated. Apparently, irradiation alters some of the links which bind together the units of fibrin so that they become more readily accessible to the action of urea.

In view of the above influence of X-rays on final gel structure it appeared desirable to test the effect of sulphydryl compounds, since sulphydryl groups may play a part in firm-gel production[4]. Addition to fibrinogen, prior to irradiation, of solutions of 10^{-3} *M* cysteine or glutathione failed to alter the radiation-induced clotting defect but prolonged the clotting time in both the irradiated and unirradiated solutions. Thioglycollic acid (10^{-3} *M*), as well as higher concentrations of cysteine (10^{-2} *M*), completely inhibited the clotting process in both the irradiated and control solutions. These findings do not exclude the possibility that the polymerization phases of the clotting process are dependent on sulphydryl, since Scheraga and Nims[2], using very high doses, found that cysteine protects radiation-sensitive sites in the fibrinogen molecule.

The foregoing changes are also accompanied by a significant reduction in the release of fibrinopeptide during the clotting of irradiated fibrinogen (500 r.). Using the method of Lorand[4], a value of 3–4 per cent peptide split was obtained from unirradiated samples; in contrast, 30 per cent less peptide was liberated after irradiation. Despite this reduction in the thrombin-induced release of fibrinopeptide, the amount of clottable protein or the ratio of clottable/total protein in the fibrin clot remained unchanged.

From the above it follows that the radiation-induced defect in clotting does not simply lead to an inactivation of the fibrinogen molecule but to a specific alteration. If it is assumed that the exposure of charged sites as a consequence of the release of peptides results in the formation of linear polymers, then the reduction in peptide liberation provides an adequate explanation of the decreased rate of clotting. The observation, however, that the characteristics of the firm gel are also altered may reflect a dependence of the terminal processes on the extent of peptide release.

The specific modification(s) in the fibrinogen molecule induced by low doses of radiation may represent a mechanism of interaction between radiation and biologically active proteins. This may be of importance with regard to generalized radiation damage.

We wish to thank Messrs. J. L. Weatherwax and L. Stanton, of the American Oncologic Hospital, for the use of the X-ray apparatus. This work was carried out while one of us (P. R.) was working under U.S. Atomic Energy Commission contract *AT*(30-1)-1554.

Paper Electrophoresis of Rat Pancreatic Juice and Water-Soluble Proteins of the Pancreas

ELECTROPHORETIC fractionation of pancreatic juice components in a dog has been described in the literature[1-4]. Some of the authors[2,3] isolated part of the fractions and studied their enzymatic activities. All authors used the free electrophoresis method with the exception of Delcourt and Delcourt[4], who employed paper electrophoresis for the separation of the different fractions.

As part of a general study of the synthesis of proteins of rat pancreas, pancreatic juice was analysed by means of paper electrophoresis. It was collected for three hours after a secretin–carbamoylcholine stimulus, as described by Junqueira, Hirsch and Rothschild[5], at 0° C. The electrophoresis of 10-μl. samples of pancreatic juice (average protein content; 6 per cent) was performed on Whatman No. 1 filter

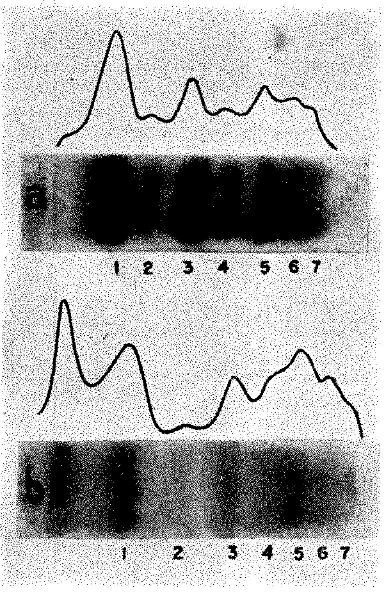

Fig. 1. *a*, Electrophoretic pattern of the rat pancreatic juice. 1—amylase; 2—ribonuclease; 3—proteolytic activity (trypsin) plus esterase and lipase activity; 5—proteolytic activity (chymotrypsin). *b*, Electrophoretic pattern of the water-soluble proteins of the rat pancreas. 1—amylase; 2—ribonuclease; 3—proteolytic activity plus esterase and lipase activity; 5, 6, 7—proteolytic activity

paper strips during 20 hr. at room temperature. Veronal-acetate buffer of pH 8·6, ionic strength 0·1, was used with a current of 110 V. 0·5 mA. per cm. in electrophoresis apparatus (No. 3276, L.K.B., Stockholm). Six or seven fractions could be separated in these conditions (Fig. 1*a*). A part of the paper was stained for proteins with amido black 10 *B* [6] and the other part cut into corresponding fractions, eluted with a suitable buffer and tested for their enzymatic activity. No lipoproteins or periodic acid–Schiff reagent-positive substances could be detected in the ionographs.

Amylolytic activity, as assayed by the method of Smith and Roe[7], was found to be associated only with fraction 1. The maximum of ribonuclease activity, determined by Rabinovitch's modification of the method described by Kunitz[8], was present in fraction 2. Residual activity could be detected in fractions 1 and 3. Lipase and esterase activity, measured by the method of Seligman and Nachlas[9], using β-naphthyllaurate as substrate, with and without taurocholate, was found to be associated with fraction 3, with little residual activity in the adjacent fractions. Esterase activity was also demonstrated directly on the paper, applying the histochemical method of Nachlas and Seligman, as modified by Gomori[10], using α-naphthylacetate as substrate. Proteolytic activity, as assayed by the Kunitz casein method[11], was found in fractions 3 and 5. Since trypsin, as well as chymotrypsin, are measured by this method, trypsin inhibitors such as ovomucoid and the soy-bean inhibitor were used, in order to distinguish the two enzymes. About 80 per cent inhibition was obtained with ovomucoid in fraction 3 and 40–50 per cent in fraction 5. The soy-bean inhibitor had a more marked effect. The results suggest that trypsin is probably associated with fraction 3 and chymotrypsin with fraction 5.

An interesting fact is that proteolytic activity appears without the addition of an activator, whereas this does not occur in fresh pancreatic juice. There is probably an autoactivation during the time of the electrophoretic run. This activation is, however, partial. On adding an activator, such as trypsin, to the different fractions, proteolytic activity appears in addition to bands 3 and 5, and also in the fast-moving bands 6 and 7. This suggests that the precursors of the proteolytic enzymes, namely, trypsinogen and chymotrypsinogen, may be located there.

Water-soluble proteins of rat pancreas, obtained from a centrifuged (40 min. at 15,000 *g*) 20 per cent aqueous homogenate of the pancreatic tissue, were subjected to paper electrophoresis as described above, using 30-μl. samples of the solution. A similar number of fractions as for the pancreatic juice was obtained (Fig. 1*b*), with an additional fraction that remained at the origin under the experimental conditions used. Amylase activity is associated with fraction 1; ribonuclease activity with fraction 2; esterase and lipase activities with fraction 3. Autoactivation of the proteolytic enzymes was only exceptionally observed. When activated with trypsin, proteolytic activity appeared in the fast-moving bands and also in fraction 2, instead of fraction 3, as in the case of the pancreatic juice.

Comparison of the Metabolic Stimulating Action of Aspirin and Thyroid

SALICYLATE is a powerful metabolic stimulant in animals (Reid, J., personal communication, 1952), in man[1] and in tissue slices[2]. In hypothyroid patients it is possible to restore the basal metabolic rate to normal levels with dosage of the order of 8 gm. aspirin daily in divided doses.

Comparison of the effects of aspirin and thyroid (given seriatim) in two cases of myxœdema shows that they possess several actions in common: both cause increased oxygen consumption, decrease in the serum cholesterol, and hæmodilution. Since many features of myxœdema which have been attributed to the low metabolic rate (for example, slow cerebration) are unaffected by aspirin, the question arises as to whether the type of metabolic stimulation produced by aspirin and that by thyroid can be similar.

Fig. 1 shows a dose-response curve for thyroid extract in myxœdematous patients, constructed from data of Means and Lerman[3]. At each dose-level the drug was given for a prolonged period, until a constant effect was obtained. This constant basal metabolic rate is taken as the effect of the given dose.

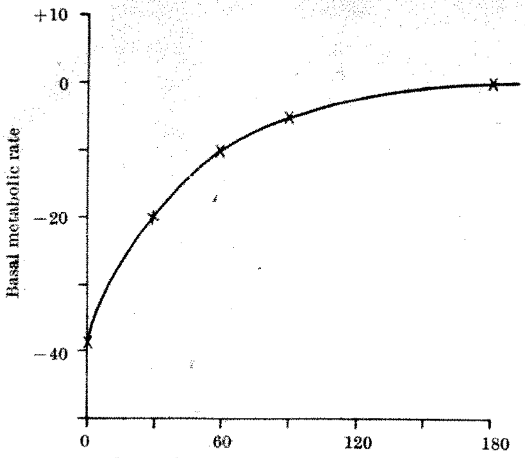

Fig. 1

Fig. 2 shows the serum salicylate-level plotted against basal metabolic rate in two female patients (*a*, age 65 years; *b*, age 43 years) with classical primary myxœdema. A similar linear relationship is obtained when dose of salicylate is used instead of serum-level.

	a	*b*
Number of observations	15	13
Correlation coefficient	0·931	0·944
Value of *P*	<0·001	<0·001

Fig. 2

The dissimilarity in the dose-response curves obtained with thyroid and with aspirin suggests that though they both produce metabolic stimulation, it is not of the same kind.

Details of this work will be published later.

Synthesis and Biological Activity of a New Potent Analogue of Oxytocin

USING the recently described method for the synthesis of oxytocin[1], it was possible to prepare structural analogues of oxytocin by replacing the isoleucyl group by valyl, leucyl or phenylalanyl groups. Of the series obtained, the valyl analogue of oxytocin ('valyl-oxytocin') was the most active and interesting substance. A description of its synthesis and some biological properties follow:

N-CBO-S-benzyl-L-cysteinyl-L-tyrosine was coupled in tetrahydrofurane by the mixed anhydride procedure with L-valine methylester to give the tripeptide ester, melting point 132°, $[\alpha]_D^{18}$ − 36° (*c*. 2·9 in methanol). This was transformed, through the hydrazide, melting point 241°, into the azide, melting point 110°, which, by reaction with the hexapeptide (N-CBO-L-glutaminyl-L-asparaginyl-S-benzyl-L-cysteinyl-L-prolyl-L-leucyl-glycinamide) gave the nonapeptide (N-CBO-S-benzyl-L-cysteinyl-L-tyrosyl-L-valyl-L-glutaminyl-L-asparaginyl-S-benzyl-L-cysteinyl-L-prolyl-L-leucyl-glycinamide), melting point 232°. 20 mgm. of the nonapeptide was dissolved in 5 ml. liquid ammonia and reduced with sodium[2]. 5 mgm. of ammonium chloride was added; the ammonia was evaporated and the residue added to 100 ml. of water, the *p*H adjusted to 6·8, carbon-dioxide-free air bubbled through the solution for 2 hr., and the *p*H adjusted to 4·5. By this procedure the cyclic octapeptide was obtained.

This solution of 'valyl-oxytocin' was assayed by several methods, the international post-pituitary standard powder being used for comparison throughout. The tests used included the blood pressure in the chicken (sodium phenobarbitone anæsthesia)[3], the isolated rat uterus[4], the isolated cat uterus, the milk ejection pressure of the rabbit mammary gland (urethane anæsthesia)[5], the rat uterus *in situ* (urethane anæsthesia), the cat uterus *in situ* (chloralose urethane anæsthesia)[6], the anti-diuresis in non-anæsthetized rats[7] and the blood pressure in spinal cats.

The effect on the blood pressure in the chicken and on the isolated rat uterus was equivalent to that of 3 I.U./ml. These two methods usually recommended for the assay of oxytocic preparations therefore produced identical results. However, by measuring the milk ejection pressure of the rabbit mammary gland, which has been claimed to be the most sensitive test for oxytocin[5], the effect was equivalent to that of 15 I.U./ml. This figure was surprising, since synthetic oxytocin exerted identical effects in all three tests.

The remarkable difference between the effect on the isolated rat uterus and blood pressure in the chicken, on one hand, and on the milk ejection pressure of the rabbit mammary gland on the other, necessitated further investigation. On the cat uterus *in situ*[6] the effect was equivalent to that of 16 I.U./ml., whereas on the cat uterus *in vitro* it was equivalent to that of 6 I.U./ml. A similar difference was also found in experiments on rats; whereas the effect on the isolated uterus was equivalent to that of 3 I.U./ml., the effect on the uterus *in vivo* was approximately equivalent to that of 10 I.U./ml.

Finally, the anti-diuretic and pressor activity was investigated. In non-anæsthetized rats 'valyl-oxytocin' had an anti-diuretic effect equivalent to that of 0·03 I.U./ml. In spinal cats its pressor activity was approximately equivalent to that of 0·015 I.U./ml. Therefore, the relationship between the pressor activity and the uterine activity of 'valyl-oxytocin' is even more in favour of the uterine activity than is the case with natural and synthetic oxytocin[5,6].

These results show that for 'valyl-oxytocin': (1) there is good correlation between the effect on the blood pressure in the chicken and that on the isolated rat uterus; (2) the effect on the milk ejection pressure of the rabbit mammary gland bears no correlation to the effect on the blood pressure in the chicken and the effect on the isolated rat uterus; (3) there are great differences between the effect on the uterus *in vitro* and on the uterus *in situ* of the same species (rats and cats); (4) there are distinct species differences in sensitivity (rats and cats).

These findings suggest that synthetic compounds with oxytocin-like properties should be tested not only on the isolated rat uterus and on the blood pressure of the chicken but also on a much larger battery of tests to define their characteristics.

Extensive investigation into the chemistry, pharmacology and clinical activity of 'valyl-oxytocin' and related compounds is being pursued, and the results will be published in detail elsewhere.

In vivo Inhibition of Oxidative Phosphorylation of Rat-liver Mitochondria by 2:4 Dinitrophenol

In a recent publication, Dianzani and Scuro[1] claimed that the oxidative phosphorylating capacity of mitochondria isolated from various rat tissues was greatly decreased 20 hr. after intraperitoneal injection of 2:4 dinitrophenol. The inhibition of P/O ratios from the mitochondria was 60 per cent; from kidney, 54 per cent; from heart, 51 per cent; and from skeletal muscle, 87 per cent.

Changes such as these are difficult to reconcile with the existing knowledge of the mode of action of 2:4 dinitrophenol. Like 3:5 dinitro-ortho-cresol[2], 2:4 dinitrophenol is an acute poison which, by intravenous or intraperitoneal injection, either kills an animal in 2–3 hr. or is followed by complete recovery in the next few hours. Further, this compound can be injected daily without any increase in susceptibility[3,4]. It has also been shown that *in vitro* inhibition of oxidative phosphorylation may be reversed by washing[5,6].

Table 1

No of animals	Treatment	Oxygen uptake (μmoles)	Inorganic phosphate uptake (μgm. atoms)	P/O ($\pm$ S.D)
5	None	3·39 ± 0·59	7·91 ± 2·0	2·36 ± 0·26
5	Dinitrophenol*	3·56 ± 0·60	8·23 ± 1·0	2·35 ± 0·26
3†	Dinitrophenol*	3·83 ± 0·92	8·92 ± 2·4	2·32 ± 0·20

* Intraperitoneal injection of aqueous solution of 2:4 dinitrophenol at 3 mgm./100 gm. body weight.

† Mitochondria isolated in sucrose.

Mitochondria prepared as in Aldridge and Cremer (ref. 7).

Each manometric flask contained: mitochondria equivalent to 250 mgm. fresh tissue; 0·02 *M* sodium phosphate buffer, *p*H 7·4; 0·001 *M* adenosine monophosphate; 0·0067 *M* magnesium sulphate; 0·025 *M* potassium chloride; 0·00001 *M* cytochrome *c*; 0·033 *M* glucose; 0·0167 *M* sodium fluoride and 300 units of yeast hexokinase ('step 3' purity, according to Berger *et al.* (ref. 8)), 0·5 ml. 30 per cent perchloric acid in side-arm. Total vol. 3·5 ml. Temperature 25° C. Gas phase, air. Potassium hydroxide in centre. Equilibrium for 7 min. followed by measurement of oxygen uptake for 10 min. Reaction stopped by tipping acid from side-arm. Phosphate on deproteinized fluid by Fiske and Subbarow (ref. 9).

In view of the importance ascribed to oxidative phosphorylation in energy metabolism and the relevance of these observations to the toxicology of 2:4 dinitrophenol and related compounds confirmation of Dianzani and Scuro's experiment was sought. Table 1 shows that there was no significant difference between the oxidative phosphorylative capacity of mitochondria isolated from the livers of normal rats and that of mitochondria from rats previously injected with 2:4 dinitrophenol. As during the preparation of these mitochondria they were washed with potassium chloride, a further experiment was made in which the mitochondria were isolated entirely in 0·25 *M* sucrose. Again no difference could be detected. Finally, six rats were each injected with 3 mgm. 2:4 dinitrophenol/100 gm. body weight on each of five successive days. These animals survived the experiment.

The discrepancy between these results and those of Dianzani and Scuro awaits elucidation.

An Estimation of the Nature of Nucleoproteins by an Analytical Method

In previous publications[1,2] we have shown that a very constant relationship exists between the amount of deoxyribonucleic acid and the amount of arginine in the nucleus of an erythrocyte; we found the ratio 5·0 in the erythrocytes of all the species we studied (trout, pike, carp, tench, perch, barbel, roach). In the case of spermatozoa of some of these species, we found that this ratio is not the same as in erythrocytes. When the sperm contains a typical protamine (trout, pike), the ratio deoxyribonucleic acid/arginine is 1·6; in other cases (carp, tench) this ratio approximates to 5·0, just as in somatic nuclei.

A similar analytical study was performed with bovine species—on isolated calf thymus nuclei and on bull sperms; it was shown that the ratio 5·0 was found in the case of the somatic nucleus (thymus) and the ratio 1·48 in the case of sperm. This result led us to think that the bull sperm probably contains a protein rich in arginine; that is, a protein of the protamine type. The nature of the protein linked to the deoxyribonucleic acid in bull sperm, and that in the sperm of other mammals, is not known for certain, for the routine methods for the extraction of nucleoproteins cannot be applied to such material. We thought that an indication of the nature of the spermatogenetic modifications of the protein linked to deoxyribonucleic acid might be given (at least in many cases) by a simple determination of the deoxyribonucleic acid/arginine ratio. This method would need but minute quantities of biological material, and could be applied to small animals, for example, insects. In order to test the validity of this hypothesis, we applied our analytical procedure to a case recently studied by Daly *et al.*[3]. These authors isolated a nucleoprotamine from rooster sperm, and a histone from the nuclei of erythrocytes. Using our analytical method, we were able to confirm these data. Expressing our results per nucleus, we found for the rooster's erythrocyte, $2 \cdot 2 \times 10^{-6}\gamma$ of deoxyribonucleic acid and $0 \cdot 45 \times 10^{-6}\gamma$ of arginine. The ratio deoxyribonucleic acid/arginine is thus 4·88. In sperms, on the contrary, we found $1 \cdot 10 \times 10^{-6}\gamma$ of deoxyribonucleic acid and $0 \cdot 78 \times 10^{-6}\gamma$ of arginine per sperm, the ratio being 1·41. This result indicates the possibility of the presence in rooster sperm of a protamine rich in arginine, which is in a good agreement with the data of Daly *et al.*

Summarizing, the study of the ratio deoxyribonucleic acid/arginine could afford a rapid procedure for an extensive study in living species of the nature of the nuclear protein linked to the deoxyribonucleic acid in the nuclei, in order to determine whether a general process exists in the biochemistry of the formation of male gametes.

Serotonin and Connective Tissue

Serotonin (= 5-hydroxytryptamine = enteramine) has been demonstrated in carcinoids of the small intestine as well as in the blood and urine of patients suffering from this disease[1]. The symptoms of these conditions are ascribed to the release of serotonin to the blood and tissues[2]. They consist primarily in cutaneous vasomotor signs (flushing), tachycardia, asthma-like dyspnœa and hyperperistalsis. Right-sided heart disease with tricuspid and pulmonal valvular lesions are noted in some but not in all cases. In prolonged cases pulmonary stenosis appears to be a fairly constant sign. Firm connective-tissue masses have been found to envelop the pelvic organs, as well as the iliac and hypogastric arteries. Considerable masses of connective tissue have also been observed deep to the cardiac valves, and microscopic examination has revealed connective tissue proliferation[3]. Articular swelling has been observed[2]. Hedinger and Gloor[3] mention the possibility that carcinoids and their metastases may secrete a substance stimulating connective-tissue formation.

It has been suggested that serotonin might act as a histamine-liberator substance, some of the clinical signs resembling a histamine effect[4]. Various histamine liberators are able to induce degranulation and disruption of tissue mast cells[5].

Since connective-tissue formation is invariably initiated by an accumulation of mast cells believed to produce important ground-substance components and to contain histamine, the effect of serotonin upon mast cells was studied.

Living connective tissue with intact circulation was studied in the cheek pouch of the hamster under nembutal anæsthesia by a method previously described[6]. Unstained living cells were studied in the phase-contrast microscope fitted with a water immersion lens and a warm stage. Mast cells stained with an aqueous solution of toluidine blue, 1 per mille, were studied in the bright-field microscope. By the last-mentioned method, the mast-cell granules stain metachromatically, indicating a content of mucopolysaccharides. Physiological saline was used as the immersion fluid.

Serotonin creatinine sulphate (National Biochemical Corp.), injected intraperitoneally in doses of 1 and 2 mgm., induced pronounced œdema of the connective tissue, and the animals showed signs of respiratory impairment as well as cyanosis of the muzzle and paws. A pronounced degranulation of the mast cells was observed within 10–20 min. When the metachromatic granular substance was no longer demonstrable in the mast-cell body, a basic structure resembling a sponge or a honeycomb was left in the cells, which were otherwise intact. Irreparable breakdown of the cells was observed only in exceptional cases.

The connective tissue formation caused by carcinoids and their metastases may be related to the degranulating effect of serotonin upon the mast cells. The tissue œdema induced by this agent is supposed to be primary to the release of water-binding mucopolysaccharides from the cells.

This work was aided by grants from Eli Lilly and Co., Indianapolis, Indiana, the Danish Anti-Cancer League, and the National Danish Association against Rheumatic Diseases.

A Substance promoting Hatching and Liberation of Young in Cirripedes

DURING their passage through the oviducal tract, the eggs of barnacles appear to be mixed with a sticky secretion. Eggs removed directly from the ovaries remain separate; but those extruded from the oviducal openings cohere in strings, and eventually clump together, forming the paired egg masses. These are at first soft and gelatinous, but gradually become firmer, presumably because the secretion binding them together hardens. There is a clearly visible membrane surrounding each mass of eggs. Though when first formed each egg-mass is joined loosely to the oviducal opening, this connexion is transient and the egg masses lie freely in the mantle cavity for practically the whole of their development. Therefore, barnacles, unlike other Crustacea which retain eggs, need not lose them during the casting of the integument, nor is ecdysis a necessary part of the process by which embryos are discharged into the sea. Casting can and does occur regularly in many species while the eggs are still retained in the mantle space[1].

Egg masses are often retained for a considerable period after reaching their final stage in development[2], and throughout this period they will hatch only if removed from the parental mantle cavity and broken up in sea water. Although the mantle cavity is in direct communication with the sea and must exchange sea water freely when the barnacle feeds, hatching evidently takes place only when the individual eggs have access to sea water. They cannot hatch when in the centre of a mass of eggs, either because it is mechanically impossible or perhaps because the oxygen supply is too limited to allow the vigorous hatching movements to take place[3]. Natural hatching in all species studied is preceded by a breaking down of the egg masses into a soft pulp of separated eggs. These leave the mantle space in the jet of water forced out during the normal cirral beat between the last pair of cirri and the carina. Hatching usually occurs to some extent in the mantle space itself; but many unhatched eggs, some still clumped in small groups, are usually expelled with the freely swimming larvæ.

Aqueous extracts of tissues comprising mantle wall or body, but not of egg masses themselves, were found to stimulate liberation. If gravid barnacles were placed in such extracts liberation was sometimes induced within 10 min. The extracts clearly influenced the egg mass itself, not the parent barnacle, since equally rapid hatching and breakdown of isolated egg masses could be observed in watchglasses containing the extracts. Preliminary experiments showed the active principle to be heat-stable and non-specific.

It was noted that individuals of *Balanus balanoides* containing fully developed eggs which were kept in well-aerated sea water in the laboratory, but not fed, did not liberate their young at the normal time. The egg masses remained coherent and in some instances, particularly in those individuals maintained at temperatures exceeding 10° C., began to decompose in the mantle cavity. If the barnacles were fed, whether on animal or plant food, liberations took place normally within one or two days. This behaviour suggests the secretion of an active substance following the ingestion of food, perhaps the same substance that could be extracted from the tissues.

This response to food would normally delay the liberation of young until conditions were suitable for their nutrition. Thorson[4] has postulated a similar behaviour in other arctic forms, notably lamellibranchs. It might explain why the southern boundary of *B. balanoides* coincides with the March isotherm of sea temperature[5]. Too high a temperature in winter would accelerate development, and the eggs might be ready to hatch while there was scarcely any planktonic food available. If the temperature remained too high during this period the basal metabolism of the fully developed embryos might rise beyond the point at which sufficient oxygen could diffuse into the egg mass for its survival.

Liberation in response to feeding might also explain the limitation of this species to estuaries in Cornwall, Brittany and other places at the southern limit of its range[6]. The greater amount of detritus might provide sufficient food to stimulate barnacles growing in these estuaries to liberate their nauplii earlier and so avert the risk of embryonic suffocation.

In an environment where high temperature is limiting, this mechanism of liberation may render the species ill-adapted, so that a small difference in nutrition would have an important influence on distribution. In the arctic, where temperatures may be low all the year round, and where the season of plankton production is short, liberation of young in response to improved nutrition would be obviously advantageous.

Production of Patulin in Apple Fruits by *Penicillium expansum*

IT has been thought unlikely that antibiotics are produced under natural conditions, (*a*) because the necessary nutrients would not usually be available and (*b*) because other micro-organisms might be expected to compete for nutrients and, in some cases, to destroy metabolically any antibiotic formed. Nevertheless, a plant parasite may have access to a relatively rich nutrient supply and may be, in early stages of an infection at least, isolated from the influence of other micro-organisms. *Penicillium expansum* is an unspecialized plant parasite, causing storage rots of apples; most freshly isolated strains produce the antibiotic patulin (synonyms: clavacin, expansine) in suitable culture media. We thought it of interest to see whether it produces patulin in apple tissues.

A strain of *P. expansum* known to produce patulin in culture was found to produce an antibiotic in apple tissues. The antibiotic had the same spectrum of antimicrobial activity as patulin, and its behaviour on paper chromatograms, using three different solvent systems, was the same as that of patulin. There seems no reason to doubt that it was, in fact, patulin. Its concentration in sap expressed from rotted tissues at times reached high levels; concentrations of the order of 600–1,000 mgm./l. (by bioassay) were found in rots of Bramley's Seedling apples. We have also found that sap from natural rots caused by *P. expansum* frequently contains an antibiotic with the antimicrobial spectrum of patulin. Thus the antibiotic patulin is produced under natural conditions, and, in view of the importance of *P. expansum* as an apple pathogen, probably in considerable quantities.

The known phytotoxic properties of patulin suggested that it might play a part in the production of rot symptoms. Strains of *P. expansum* which produce little or no patulin in culture media also produced no detectable quantities in apple fruits and yet caused equally vigorous rots. Thus it seems unlikely that patulin is concerned in pathogenesis. We hope to deal with this point more fully, in a later publication, and to consider at the same time the role of pectic enzymes. However, it is interesting to speculate whether the production of such substances as patulin, fusaric acid[1] and alternaric acid[2] in plant tissues by fungal parasites may not to some extent discourage secondary invaders, preserving territory, as it were, for the primary parasite.

Response of Animal Fibres to Acid Attack

The stress–strain curves given by a wide range of animal fibres in air or water are practically alike, apart from differences in the low-strain region due to the presence of crimp. It has now been observed that even closely similar wools can exhibit substantial differences in the mechanical properties of their fibres, and corresponding differences in solubility in alkali, after exposure to chemical attack, such as boiling acid solution.

Such differences had been found to exist earlier among keratin fibres from different animal species[1]; but their occurrence between wools from the same type of sheep was unexpected.

The two wools used in these studies were closely similar in mean diameter (21·9 and 22·1μ, respectively), but differed in their crimp-level (14·8 and 8·9 crimps/in. in the staple). Samples of clean intact wool were treated under reflux with 100 vol. of boiling 0·04 *N* sulphuric acid for various times, following the procedure used earlier in this laboratory[1,2]; the alkali solubility was then determined, and the rate-constants for the acid-sensitizing reaction calculated, assuming two concurrent first-order reactions, by fitting the equation

$$\text{wool}_t = F_o e^{-k_o t} + F_p e^{-k_p t}$$

where wool_t is the fraction of wool found insoluble in the alkali-solubility test after *t* hours of exposure to acid. The '*o*' fraction presumably corresponds to the ortho portion of the fibre cortex, and the '*p*' to the para[1]; but this is not of primary importance to the present work. The results obtained are given in Table 1.

Table 1

Wool	F_o	k_o	F_p	k_p
High crimp	0·513	0·377	0·408	0·0440
Low crimp	0·521	0·458	0·408	0·0830
P		0·05		<0·001

Both rate constants are greater for the low-crimp wool, indicating that it is more susceptible to acid attack.

Force-extension tests to break were made on the Instron tensile tester at 70° F., in aqueous borate buffer, *p*H 9·2, at a constant rate of extension[3] of 50 per cent/min.; eighteen fibres were examined for each wool in the intact state and after two exposures to acid. The results for two mechanical properties of the fibres, together with the corresponding alkali-insolubility values, are reported in Table 2.

Table 2

Time in acid (hr.)	Alkali-insolubility			Elastic modulus (gm./cm.^{2}) $\times 10^{-6}$			Breaking energy (gm.-cm./cm.^{3}) $\times 10^{-4}$		
	High cr.	Low cr.	*P**	High cr.	Low cr.	*P**	High cr.	Low cr.	*P**
0	93·4	94·1	—	13·6	14·5	0·2	34·1	36·7	0·2
4	47·0	39·1	0·001	8·4	6·7	0·01	14·3	10·2	0·0
16	24·7	16·6	0·001	4·0	3·6	—	3·4	2·7	—

* Values greater than 0·2 not listed

All the parameters derived from the stress–strain curve show, like the alkali-insolubility values, that the low-crimp wool has suffered greater degradation as a result of acid treatment. The properties derived from the yield portion of the curve (stress at 20 per cent extension, energy for 20 per cent extension) exhibit less change after acid attack, and differentiate less clearly between the two wools than either the low-strain properties (uncrimping stress, elastic modulus, stress at 5 per cent extension) or the properties at break (particularly breaking stress and breaking energy).

The difference between the two wools in their susceptibility to chemical degradation is sufficiently large to be detectable in the properties of fibres from fabric dyed with metallized acid dyestuffs; furthermore, this difference is reflected in the resistance of the fabric to flex-abrasion, wet, determined on the Stoll tester[4].

Preliminary results on other wools do not suggest that the difference in response to acid attack between the two specimens studied is related directly to their crimp configuration.

Measurement of Mean Red-Cell Thickness by the Use of a Probability Function

WHEN attempting to find the mean thickness of any kind of circular and biconcave red cell, one has either to be content with the mean corpuscular thickness, obtained by treating the cell as a cylinder and dividing the mean cell volume by πr^2, or one has to measure the dimensions of red cells on edge[1], thus obtaining the greatest thickness, the least thickness, and so on. The former method does not take the shape of the cell into consideration, and the latter method is laborious. This communication describes a new method, intermediate in accuracy but sufficiently reliable for many purposes. It depends on the fact that the number of red cells seen on edge, in a preparation in which the cells are randomly oriented, depends on the mean dimensions of the cells, including the diameter. Virtually no cell will be seen exactly on edge ; but a number will present themselves in the direction of observation in such a way that their observed thickness will be less than a selected value w—where w is a little larger than t, the true mean thickness. The probability f of such cells being seen in the preparation is

$$f = \frac{w - t}{d - t} \qquad (1)$$

an expression for which we are indebted to Dr. R. T. Cox (the proof of this expression is a little too long to be included here ; but we shall be glad to communicate it to anyone who is interested), and which treats the cross-section of the red cell as a rectangle with a semicircle at each end.

A preparation of red cells in plasma is made between slide and coverslip, and is examined under conditions of reasonable high resolution (× 20 objective, N.A. 0·5, × 5 eyepiece, and Kohler illumination). The preparation is stirred up by pressing on the coverslip so that the red cells move in the currents thus produced, and several fields are photographed (Leica 111 *f* camera with Adox *KB*-17 film) at an exposure of 0·001 sec., provided by a Strobonar IV electronic flash. After development, the fields are projected at a magnification of about × 800, and a cell is considered to be on edge if its image falls within two lines separated by a distance w and drawn on a glass plate ; it is convenient to choose two values for w, one about 1·5 times and the other about twice the estimated cell thickness. The values chosen for w are not particularly important, although they must be known exactly in μ. The number of red cells on edge and the total number of cells in the fields examined give f, from which t, the mean cell thickness, can be calculated for each of the two values of w. Virtually the same value of t is usually obtained from the two values of w.

This method has given excellent results. For the red cells of man $t = 2{\cdot}07 \pm 0{\cdot}1\mu$, which is in good agreement with the value found by photography of human red cells on edge[1]. For rabbit red cells, $t = 2{\cdot}1 \pm 0{\cdot}1\mu$, which again agrees with direct observations if one allows for the limitations which the latter suffer because of diffraction phenomena at the cell edge. For the mouse red cell, $t = 2{\cdot}05 \pm 0{\cdot}05\mu$.

A corollary to expression (1) is that if no red cell or ghost presents itself on edge, the cells or ghosts are necessarily spherical. Their volume is then $4\pi r^3/3$, where r is their radius, and their surface area is $4\pi r^2$.

Electrical Properties of the Plasma Membrane of Erythrocytes at Low Frequencies

EARLIER investigations of the dielectric properties of biological interfaces dealt with the plasma membrane of erythrocytes and obtained from its capacitance a value of its thickness near $10\varepsilon_M$A., where ε_M is dielectric constant of membrane[1]. Other contributions considered the possibility of a frequency dependence of cellular membrane impedance which can be expressed by a power law[2]. Both frequency dependence of membrane and complexity arising from variability in cell size and shape may affect similarly dielectric properties of cellular suspensions in the R_F-range.

Thus, measurements of biological interfaces at lower frequencies than previously investigated are indicated to differentiate power law behaviour of interface from form and size variation effects.

This study was undertaken to obtain data of resistivity and capacitance of erythrocytes at low frequencies. Accurate impedance measurements on red cell suspensions were obtained in a frequency-range of 10–200,000 c./s. Heparinized fresh beef blood was washed with Ringer tyrode, *p*H 7·6, and centrifuged to 80–90 per cent volume concentration of erythrocytes. The packing was done to reduce artefacts due to electrode polarization[3]. This concentrated suspension was placed in a cylindrical electrolytic cell, the impedance of which was measured in a precision bridge[4]. Temperature was stabilized to 25° C. ± 0·01° C. Effects of distributed capacitances and leakage conductances were eliminated by a substitution technique. The measurements of impedance as function of frequency (f) were made with high accuracy, resistance to ± 0·0005 per cent except at 10 c./s. and capacity to $(0{\cdot}5/f_{\text{kc.}} \pm 0{\cdot}5)$ per cent. Changes due to small temperature variations and sedimentation were eliminated by alternating experimental measurements with control readings at 1 kc./s. The small drift of the control readings with time was found independent of frequency and used for determining corrections for the experimental data at other frequencies.

Electrode polarization impedance, which appears in series with the sample impedance, was nearly independent of sample volume. Hence, the difference between measurements at two electrode spacings could be taken to be proportional to the impedance of the differential blood volume[3,5]. Accuracy of these difference measurements was kept high by minimizing

Table 1

2	0·996	200	0·961

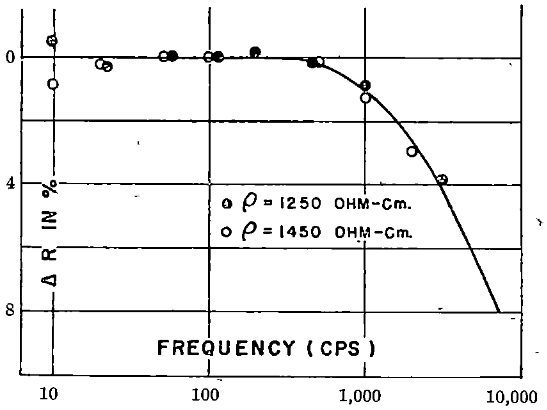

Fig 1

polarization with electrodes heavily covered with platinum black and using large electrode spacing (up to 15 cm.). Fig. 1 represents specific resistance ρ of two samples. Results are typical of all samples investigated. Table 1 gives dielectric constant values, averaging eight samples. The drop in resistance above 1 kc./s. and in dielectric constant above 10 kc./s. is the result of the known dispersion caused by the cell interior. Measurements have also been carried out with rabbit blood with the same results. The frequency dependence reported previously by others for rabbit erythrocytes[5] between 500 and 5,000 c./s. cannot be confirmed.

The results in both resistance and capacitance support the frequency independent nature of the erythrocyte membrane. If a power law $C=C'f^{-m}$ would characterize membrane capacitance, then accuracy of capacitance data corresponds to m deviating from zero by less than 0·004, that is, the phase-angle of the interface must be equal to 90° within 0·4°. From the frequency independence of resistance, and from measured capacitance of suspensions and known capacitance of plasma membrane[1], it follows that the conductance of the plasma membrane per cm.^{2} of its surface is constant between 20 and 500 c./s. within 0·1m.mho. Electrical relaxation effects due to structure occur if different molecular layers are arranged in series[6]. Presuming such a structure, our results mean that dielectric losses of these layers are extremely small, placing the relaxation effect outside our range of observation. A more likely possibility to explain our results is a mosaic structure of the lipid–protein complexes[7]. Such a mosaic arrangement cannot show a frequency dependence, at least as long as its components are independent of frequency.

This investigation was supported by a research grant *H*-1253(*C*2) from the National Institutes of Health, Public Health Service.

Energy Relations of Mitotic Activity in Mouse Hair Bulbs

It is now recognized, especially from studies on the physiology of adult epidermis, that the energy requirements of mitotic activity are high[1]. There is a marked diurnal rhythm in epidermal mitotic activity, and this appears to be determined by variations in the rate of uptake of glucose from the blood. Hair bulbs contain cells which are epidermal derivatives; but their mitotic activity follows a remarkably individual pattern, which is not influenced by the diurnal rhythm. Waves of hair-growth pass slowly across the body of a mouse, and, according to the position of these waves, the hair bulbs are either completely quiescent or are engaged in the most violent mitotic activity.

It has been shown *in vitro* that epidermal mitotic activity is dependent on an adequate supply of glucose and oxygen so that, in the absence of one or other of these substances, mitosis is severely depressed or even eliminated. Efficient energy-production through respiration is essential to epidermal mitotic activity, and such activity cannot be supported by anaerobic means, although in embryonic tissues this is evidently possible[2]. The question now arises whether the peculiarly violent and short-lived mitotic activity of the hair bulbs in the growth zone is also dependent on respiration, or whether it is supported by some alternative or ancillary mechanism. The following experiments were designed to provide an answer.

Adult male mice of Kreyberg's *WLL* strain had their body hair removed by electric clippers, and within a few days the regions of active hair growth became obvious. When the leading edge of the advancing growth-wave had reached the flank regions, the mice were killed and a strip of skin containing active hair bulbs was removed from both sides of the body and cut into small pieces (size approximately 50 mm. × 100 mm.). The skin fragments, arranged so that each group consisted of three pieces of skin each taken from a different animal, were immersed in a phosphate-buffered saline medium maintained at 38° C. in a Warburg flask. They were incubated for 1 hr. in order to eliminate those mitoses which were present in the hair bulbs when the skin was taken from the mouse. Colchicine was then added and the incubation continued for a further 4 hr. During this period, all the developing mitoses were arrested in the metaphase by the colchicine. Full details of this technique have been given elsewhere[3].

In addition to determining the effects of the presence or absence of glucose and oxygen, a study was also made of the effects of cyanide (which inhibits the cytochrome system), of fluoride (which inhibits glucolysis) and of 2 : 4-dinitrophenol (which is said to inhibit energy transfer). The results, taken from sections cut 7μ thick, are given in Table 1.

Accurate mitosis counts, similar to those previously obtained for epidermis, were difficult to make; but it was found that the results were so uniform and so obvious that this was unimportant. There was high mitotic activity in the group given both glucose and oxygen, low mitotic activity in the group deprived of glucose, and no mitotic activity at all in the groups treated with nitrogen and with optimum concentrations of cyanide, fluoride and 2 : 4-dinitrophenol.

It is evident from these results that the energy relations of mitosis in hair bulbs are similar to those

Table 1. MITOTIC ACTIVITY IN MOUSE HAIR BULBS INCUBATED *in vitro* FOR 4 HR. AT 38° C.

Note: ++ indicates high mitotic activity.
+ indicates low mitotic activity.
0 indicates full inhibition of mitotic activity.

already described for epidermis. In the first place, it appears that sufficient energy is stored during the antephase to ensure that, when glucolysis and respiration are inhibited, any mitoses already in progress are capable of passing to completion. In the second place, it is clear that few, if any, new mitoses can develop in cells in which the antephase storage of energy is prevented by the absence of glucose or oxygen. Normally, in the rapidly dividing cells of the hair bulbs this storage of energy must occur very quickly. It evidently depends on active respiration, and it cannot be accomplished by glucolysis alone.

It has been suggested that the normal ability of an epidermal cell to undergo mitosis is limited by the degree of activity of the cell surface in absorbing glucose. If the same is true in the case of mouse hair bulbs, then it appears that, according to the stage of the hair cycle, these cells must alternate between an exceedingly low and an exceedingly high rate of glucose uptake, or, in other words, between a state of very low and very high cell-surface activity.

We thank Miss Anne Rogers for her assistance in this investigation, which was supported by a grant from the British Empire Cancer Campaign.

Assay of Spider Venom and Antivenene in *Drosophila*

DURING studies on the toxicity of the venom of the Australian red back spider (*L. hasseltii*) it was found that the venom injected into *Drosophila* causes paralysis of the insect. This effect has been utilized for assaying antivenene.

Venom was obtained from the dissected venom glands of *L. hasseltii* as described elsewhere[1]. About 0·2 c.mm. of varying concentrations of venom was injected with a capillary pipette into the thorax of *Drosophila* under carbon dioxide anæsthesia. The results are shown in Table 1, where the amount of venom which was injected is expressed in fractions of the venom of one spider. With the higher concentrations of venom, the insects became paralysed within 5–20 min. after the injection. With concentrations of venom near the minimum lethal dose the insects showed progressive difficulty in turning over when they were made to fall on their backs and became paralysed without recovery during the next 24 hr. Results were recorded 24 hr. after the injections. It can be seen from Table 1 that 5 × 10⁻⁶ of the amount of venom contained in one spider constituted the minimum lethal dose for *Drosophila*. It has been found previously that on the average one spider contains about 0·1 mgm. of venom. Thus 5 × 10⁻⁷ mgm. of spider venom was sufficient to kill one *Drosophila* weighing about 1 mgm. A mouse of 20 gm. is usually killed by 0·2 of the amount of venom of one spider. On the basis of body-weight the venom of *L. hasseltii* is therefore approximately eight times more toxic in *Drosophila* than in the mouse. Millot[2] suggested that spider venom is most toxic to those animals on which the spider normally feeds.

Table 1. TOXICITY OF SPIDER VENOM IN *Drosophila*

Amount of venom in fractions of one spider ($\times 10^{-3}$)	No. of insects	No. paralysed
0·2	6	6
0·1	3	3
0·05	3	3
0·02	3	3
0·01	3	3
0·005	3	3
0·002	3	0
0·001	3	0
0·0005	3	0

Antivenene was prepared in a rabbit using venom adsorbed on aluminium phosphate[1]. The antivenene (*F*7) used here was obtained seven days after the second dose of venom. Using mice, it was found that one millilitre of serum neutralized the venom of four spiders.

For assaying antivenene in *Drosophila*, equal volumes of fixed quantities of venom were mixed with varying dilutions of serum. Each dose of 0·2 c.mm. contained the venom of 0·0001 spider which corresponded to twenty lethal doses. Table 2 shows the amounts of serum injected with each dose and the results which were obtained. It can be seen that 0·3 × 10⁻⁴ ml. of serum neutralized 1 × 10⁻⁴ of the amount of venom contained in one spider. One millilitre of serum, therefore, neutralizes the venom of about 3·3 spiders. This result agreed reasonably well with that obtained when the same serum was assayed in mice.

The use of *Drosophila* as an index of antigen–antibody reaction for the titration of spider-antivenene enables a larger number of lethal doses of venom to be injected and neutralized than is practicable in the case of mice. A more reliable estimate of the potency of the serum is therefore possible[3]. At the same time, there is a considerable saving in the amount of venom required for assaying antivenene, and results are available within 24 hr.

The method here described is simple and might prove useful for assaying antisera of medical import-

Table 2. ASSAY OF SPIDER ANTIVENENE IN *Drosophila*

Histamine and Histidine in Excreta of the Blood-sucking Bug *Rhodnius prolixus*

Paper chromatographic studies of the dry excreta of *Rhodnius* fed in the laboratory on the rabbit have shown the presence of the following amino-acids or related compounds: leucine, histidine, histamine, taurine, glycine, valine, phenylalanine and alanine—the first three giving particularly intense spots with ninhydrin.

The presence of histidine and its amine in substantial concentration was confirmed by tests with the diazo reagent of Pauly as applied to chromatograms by Dent[1]. Histidine was further checked by parallel runs with pure substance. The histamine spot corresponds to the position allotted to it in the literature[1] and when eluted with 0·9 per cent sodium chloride solution, and scratched into the skin, it gave a marked reaction compared to a negative response with distilled water. A value of 0·041 mgm. histamine/100 mgm. dry excreta was obtained by an assay kindly performed by Dr. W. E. Ormerod on guinea-pig ileum by comparing the contractions produced with those produced by a standard dose of known histamine concentration.

A semi-quantitative study of the free amino-acids in *Rhodnius* hæmolymph by the method of Auclair and Dubreuil[2] has shown that histidine accounts for almost 35 per cent of the total free amino-acids detected (2,594 µgm./ml.). It is well in excess of all others in the amino-acid picture. It was not detected in excreta of bugs fed on horse serum through a rubber membrane, and histamine was present in low concentration. Sterile bugs, that is, bugs deprived of their intestinal micro-symbionts, *Actinomyces rhodnii*, gave excreta with a significant decrease of histidine but with an intense histamine spot.

The high concentration of histidine in both hæmolymph and excreta of *Rhodnius* is similar to that found in *Bombyx mori*, where it has been detected in hæmolymph of larvæ[3] in equally high concentration[7], of pupæ[4] and of adults[5]. In addition, it has been found in large amount in larval fæces[6] and adult urine[5]. There appear to be no previous records of the detection of histamine in insect excreta or tissues.

Histamine was not detected in *Rhodnius* hæmolymph at any time, so one can assume that decarboxylation of histidine has occurred in the gut prior to elimination of the amine. Since it appears in excreta of sterile insects, it must arise as a result of tissue decarboxylation of histidine and not by bacterial agency. Also, the absence of histidine (and most of the amine) in excreta of serum-fed bugs suggests that both may be derived predominantly from the substantial concentration of histidine in the dietary blood, where it forms 6–10 per cent of the globin derived from hæmoglobin[8]. In other words, the red blood cells in the diet account for the high concentration of histidine and its amine in the excreta. There is further confirmation for this, as histamine does not appear in the copious urine immediately after the blood meal but only in the excretory products of digestion which takes place weeks after ingestion of the blood. Ingested hæmoglobin may remain red for several weeks[9]. The lower concentration of histidine in excreta of sterile insects is difficult to explain as it does not correspond to any change in its amine, which is present in high concentration. It is possible that the intestinal symbionts are contributing histidine to the host.

The detection of histamine, a 'tissue poison', in high concentration in the gut is particularly interesting. It is curious to find an organism converting a harmless substance into a 'toxic' derivative before excreting it. The presence of both these substances could be further elucidated by studies on the excreta of other blood-sucking insects.

This research formed part of a study for the degree of Ph.D. of the University of London and was carried out under the late Prof. P. A. Buxton, whose fundamental criticisms and assistance were most valuable. It is a pleasure to thank the South African Council for Scientific and Industrial Research for generous financial support during the study.

The Small Saphenous Vein as a Route for Intravenous Injection in the White Rat

A number of years ago, in searching for an accessible vessel from which blood could readily be obtained several times a week, we found that the small saphenous vein could easily be visualized and entered through the skin on the dorsum of the rat's foot. This vessel has since proved far more satisfactory than the commonly used tail vein for either bleeding or injection[1,2]. The technique of injection by this route has been briefly, but obscurely, described[2], and it thus remains not generally known.

The location of the small saphenous vein on the foot is shown in Fig. 1. The unanæsthetized rat is prepared for injection by wrapping in a towel or by insertion in a restraining cylinder. In either case, the one leg chosen for injection is left protruding. Shaving the area over the vein not only makes it easier to see through the skin, but also by provoking increased circulation causes the vein to distend prominently. The latter effect may be enhanced by washing the skin with 70 per cent alcohol and by snapping one's finger against the foot; application

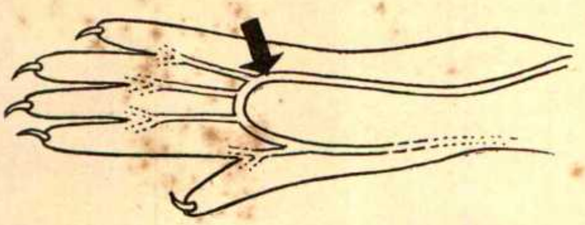

Fig. 1. Dorsal venous arch on the right hind foot of a rat. The small saphenous vein forms the lateral limb of the arch proximal to the arrow

of heat has never been necessary. The operator holds the foot by the toes during the procedure, and an assistant aids by holding the knee in such a manner that its sudden flexion and consequent withdrawal of the foot are prevented. A 1-in., 26-gauge hypodermic needle directed toward the ankle is inserted through the skin and into the vein at the approximate point indicated by the arrow in Fig. 1. With pressure of the operator's thumb over the point of insertion, the foot and needle are held firmly between thumb and index finger so that with any slight movement of the foot the needle and syringe move with it. Extreme variations from the venous pattern illustrated are rare and constitute no special hazard.

A *p*H Gradient Agar Plate

IT is often advantageous for the microbiologist to know the *p*H limits within which a micro-organism will grow, and the influence of *p*H on the antimicrobial action of various drugs. Customarily, such studies are carried out in a series of separate vessels, each adjusted to a different *p*H-level. This note describes a modification of the Szybalski gradient plate technique[1] so as to provide a *p*H gradient across the surface of an agar plate, thus facilitating studies involving *p*H effects on the growth of micro-organisms.

The Szybalski technique involves solidification of a layer of agar (containing an antibiotic) while the Petri dish is held in an inclined position. An equal amount of agar is then added which is allowed to harden while the plate is level, thus forming two complementary slanted layers, and establishing a graded antibiotic concentration across the plate. The modification presented involves the introduction of K_2HPO_4 into the lower layer, and KH_2PO_4 into the upper layer (antibiotic omitted). In practice $1M$ buffer solutions are sterilized separately and added to the medium just prior to pouring (1 : 10 v/v). These plates develop a gradient ranging from about *p*H 5·6 to *p*H 7·8 and which is readily visualized by placing filter paper strips, each impregnated with a different *p*H indicator, on the agar surface. The colours formed provide a convenient guide to the *p*H at any position along the gradient. A photograph of such a plate with indicators transferred to the agar (after removal of the paper strips) is shown in Fig. 1.

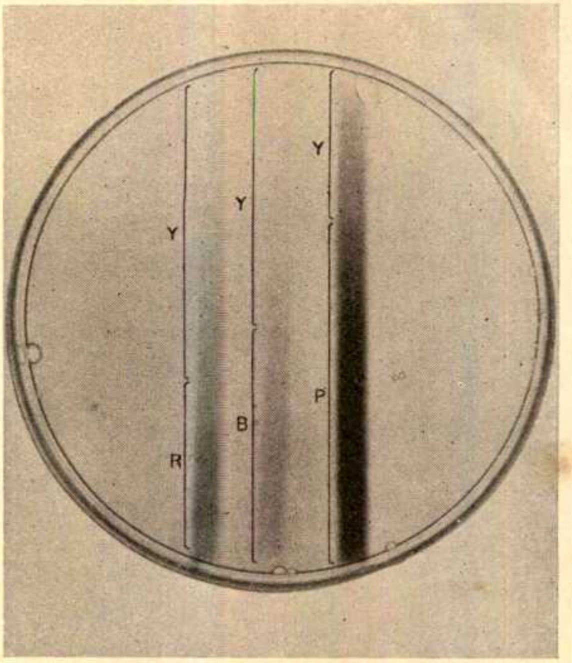

Fig. 1. *p*H gradient plate, showing *p*H indicators transferred to the agar by contacting the agar for about ten minutes with filter paper strips impregnated with the indicator. Indicators are (left to right) phenol red, brom thymol blue, brom cresol purple. Bottom is alkaline, top acidic

The influence of *p*H upon antibiotic action can be determined in several ways. The simplest is to incorporate the antibiotic in a thin surface layer (10 ml. per 150 mm. plate) of 2 per cent agar. The test

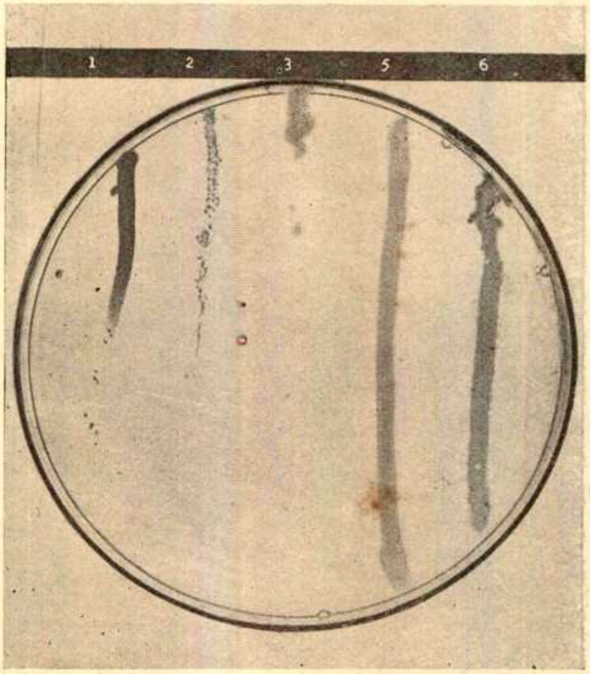

Fig. 2. Influence of *p*H on the antibacterial action of streptomycin. 1, *Staphylococcus aureus* (H). 2, *S. aureus* FDA 209. 3, *Bacillus megaterium* B-938. 5, *Escherichia coli* 456. 6, *Serratia marscesens*. Surface layer contains 20 p.p.m. Note absence of growth in alkaline regions for organisms 1, 2, 3

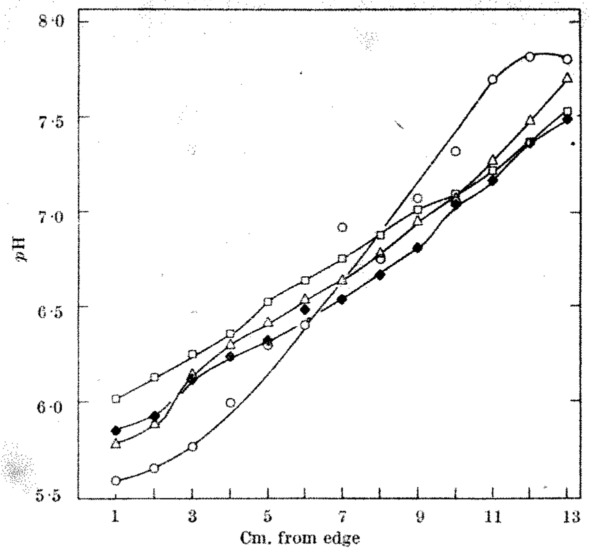

Fig. 3. Stability of pH gradient. ○———○, 1 hr. after pouring agar; △———△, 1 day; ■———■, 2 days; □———□, 8 days; pH determined with glass electrode; plates held at 25° C., 0 to 4 days; at 5° C., 4 to 8 days

organisms are then streaked along the gradient with swab sticks soaked in suspensions of 24-hr. cultures. Several plates, each with a different antibiotic concentration, are generally prepared, along with a control plate from which the antibiotic is omitted. Fig. 2 shows the increased effectiveness of streptomycin in the alkaline region[2]. An alternative method (cf. Streitfeld and Saslaw[3]) involves placing a filter-paper strip impregnated with the antibiotic on the plate and overlayering with a thin layer of 1 per cent agar containing the inoculum. Flaring of the inhibition zone indicates increased activity in that region of the gradient.

The pH limits within which an organism will grow may be readily determined by omitting the antibiotic from the surface layer, and streaking. By using H_3PO_4 instead of K_2HPO_4 a pH range of 2 to 5 may be obtained.

The pH gradient is quickly established, and changes but little in 48 hr. On the 150-mm. plates shown, the pH values shifted appreciably only at the extremes of the gradient where buffering capacity is poor (Fig. 3).

Generic Status of *Glossopteris*, *Gangamopteris* and *Palæovittaria*

Though the *Glossopteris* flora has been known for more than a hundred years now, our knowledge of this flora does not extend beyond the gross features of the plants comprising it. As is well known, the fronds of the three important genera, *Glossopteris*, *Gangamopteris* and *Palæovittaria* are more or less similar in external form and are usually distinguished by the presence or absence of midrib and anastomosing of the secondary veins. But many times the characters of one genus merge into another and then it becomes difficult to refer it definitely to any one of the three genera. Some good examples are, *Glossopteris mitchelli*, *Glossopteris intermittans*, *Glossopteris decipiens* and *Gangamopteris indica*. Owing to such inconsistency shown by these external characters, doubts were raised in the past about the generic status of *Gangamopteris* and *Palæovittaria*. It appears that between the three genera there are no sharply defined distinguishing features, and the criteria like the presence or absence of midrib and the anastomosing of secondary veins are too inconsistent to be relied upon as generic characters.

As Prof. B. Sahni[1] remarked, while describing the cuticle of *Glossopteris angustifolia*, in dealing with material of this nature any information that took us beyond the gross features would be welcome. Fortunately in India these plant remains are found as impressions, many of which are carbonized and therefore suitable for cuticular studies.

Such studies of the *Glossopteris* flora of India have now been taken up at this Institute. The late Dr. P. N. Srivastava made cuticular studies of the following:

Glossopteris browniana, *G.* cf. *divergens*, *G. communis*, *G. communis* var. *stenoneura*, *G. conspicua*, *G. formosa*, *G. retifera*, *G. damudica*, *G. intermittans*, *G. tænio-pterioides*, *G. sahnii*, *G. arberi*, *G. longicaulis*, *G. tænioides*, *Gangamopteris* cf. *cyclopteroides*, *G.* cf *hughesi*, *G. indica*, *G. flexuosa*, *G.* sp. *A.*, *G.* sp. *B. Palæovittaria kurzi*.

He compared all his specimens with the type specimens which were available, and it is provisionally presumed that the specific determinations are correct.

Srivastava's cuticular studies show that it is again not possible to delimit the three genera as defined at present on the basis of epidermal characters, because there are species in two genera which show very similar characters and some species of a single genus show such diversity as cannot be regarded only of specific importance. It is therefore evident that the three genera include diverse types, perhaps belonging to different genera, but possessing somewhat similar external features.

If only epidermal characters are taken into consideration, the various species of the three genera described by Srivastava fall into six groups which may provisionally be considered as of generic rank. For example, *Glossopteris angustifolia* and *G. retifera* might well be the species of a single group, whereas *G. formosa* and *G. communis* appear to be the species of another group. Similarly, *Gangamopteris* cf. *cyclopteroides* and *G.* cf. *hughesi* are the species of two distinct groups. Srivastava's studies are shortly to be published in full in the *Palaeobotanist*.

However, before the three genera are broken up into natural genera, one important fact has to be taken into consideration. Recently some fructifications have been described as borne on the leaves of certain *Glossopteris* species[2] and it can be hoped that similar discoveries may be made in the case of other related genera. When such organs are found in connexion it is natural to connect them together and define more exactly the taxonomic limits of the plant to which they belong. But before doing so in the case of *Glossopteris* and other related genera it would be desirable if the true identity of the leaves is first established on the basis of cuticular study (provided, of course, the cuticle is available). Otherwise, as Srivastava's studies have shown, the identification of a fructification-bearing leaf based only on external features may be wrong to start with and consequently lead to wrong conclusions regarding the definition of the plant represented by these organs.

Polyploidy and Radiosensitivity

THE effect of polyploidy on the radiosensitivity of cells has been the object of some discussion in the past, and it may be of some practical importance in such cases as cancer therapy, for example, since tumours are often mixed diploid–polyploid populations[1,2]. For chromosomal aberration production by radiation, polyploid sensitivity equal to[3,4], greater than[3], and less than[5,6] the diploid have been reported. Each of the various experiments involved a comparison of different diploid and polyploid species, and the lack of agreement between the experiments may be due to intrinsic differences in species sensitivity, rather than to the effect of polyploidy itself.

The ideal situation—irradiation within a single tissue or organ of a single mixed population of normal cells and polyploid cells derived from them—was realized through a fortunate accident in a *Tradescantia* radiation experiment designed for another purpose. A single *Tradescantia paludosa* flower bud (made into a single acetocarmine slide) was found with a mixed population of haploid and diploid microspores. The bud had been irradiated four days previously (500 r. of 250-kVp. X-rays in 1 min., hvl., 1·45 mm. of copper) while the cells were in postmeiotic interphase, an extended period of uniform radiosensitivity; the bud was examined at the microspore mitotic division. About half (48 per cent) of the cells were diploids.

Chromosome aberrations were carefully counted at metaphase in 50 of the haploid (6-chromosome) and 25 of the diploid (12-chromosome) microspores, with the results given in Table 1.

Table 1. CHROMOSOME ABERRATION PRODUCTION BY 500 R. OF X-RAYS IN HAPLOID AND DIPLOID MICROSPORES WITHIN A SINGLE FLOWER BUD OF *Tradescantia*

Cell type	No. of cells	Aberrations per 100 cells					
		Exchanges			Deletions		
		Intrachange, interarm (centric rings)	Interchange* (dicentrics, etc.)	Total ± S. E.	Interstitial 'minutes'	Terminal	Total ± S. E.
Haploid (6 chromosomes)	50	22	160	182 ± 19	292	60	352 ± 26
Diploid (12 chomosomes)	25	16	344	360 ± 38	624	157	776 ± 56
Ratio of diploid to haploid							
aberrations per cell				2·0 : 1			2·2 : 1
aberrations per chromosome				0·99 : 1			1·1 : 1

* No. of interchanges = 1 (dicentrics) +2 (tricentrics) + 3 (quadricentrics) + . . . ; for haploid cells = 1 (82) + 2 (24) +3 (10) + 4 (0) = 160; for diploid cells = 1 (240) + 2 (32) + 3 (8) + 4 (4) = 344.

The aberrations observed in both haploid and diploid cells are the customary chromosome kinds resulting from irradiation of undivided chromosomes in interphase. Per cell, the diploid cells have almost exactly twice as many aberrations as the haploid. However, *per chromosome* (since there are twice as many chromosomes per cell in the diploid) the aberration frequency is the same in the diploid and haploid cells. Thus, in the ideal situation of mixed cells in the same tissue, we can say that chromosomal radiosensitivity, or sensitivity per unit length of chromosome, is identical in haploid and diploid cells.

This conclusion probably is not compromised by differences in stage and sensitivity of the haploid and diploid cells, which could result from a possible difference in the rate of development of the cells. Both kinds of cells displayed only the chromosome type of aberrations, which indicates that both were in the same stage, interphase, when irradiated. In addition, radiosensitivity in this interphase is known to be uniform for not less than one day before and one day after the time the radiation was delivered[5].

The observation that for the same dose diploid cells have only twice as many exchange aberrations per cell as the haploid cells affords geometric evidence of the limitation of space over which chromosome breaks can interact to produce an exchange. It is known that with X-rays, exchange aberrations, which result from the interaction of two independently produced breaks, increase as the square of the dose; it is believed with considerable reason that the breaks increase linearly with dose[7]. Now, per nucleus, a doubling of the number of breaks can be achieved by doubling either the dose (chromosome number constant) or the chromosome number (dose constant). In terms of concentration, doubling dose doubles the number of breaks per nucleus, and also breaks per unit volume; however, doubling chromosome number doubles only breaks per nucleus—breaks per unit volume remain the same if volume is also doubled. The ratio of diploid to haploid volumes, both cellular and nuclear, on this slide was roughly about 2·8 : 1, as estimated from the ratio of measurements made on pairs of cells in the same stage and lying side by side; total chromosome length, from metaphase measurements, was in the ratio 2 : 1. The finding that, for the same dose, a diploid cell has twice, not four times, as many aberrations as a haploid cell shows that breaks do not exchange freely over the entire volume of the nucleus but only over a very limited volume. Two breaks, to exchange, must be very close together.

This work was performed under Contract No. W-7405-eng-26 for the U.S. Atomic Energy Commission.

Allium neapolitanum: a Mixed Species

In two samples of *Allium neapolitanum* bulbs, received from Van Tubergen, Holland, Levan[1] reported 14 and 28 chromosomes. Feinbrun[2] also reported the tetraploid form ($2n = 28$) of this species growing wild in Palestine. In a sample I have received from de Jager's, Holland, I have found only the diploid. In a second sample, however, there were again tetraploids; in addition there were two new types, triploids ($2n = 21$) and pentaploids ($2n = 35$).

No great differences were observed in chromosome form between the four strains. All of them had chromosomes, ranging in size from 8μ to 12μ, with median or submedian centromeres. However, an interesting feature was observed in one small chromosome of the triploid and occasionally of the tetraploid form. There was a pronounced attenuation of the centromere, which had the appearance of a long thread joining the two arms. An analogous situation has been described in several species. It has been attributed to two possibilities: (1) to unspiralized heterochromatin at one side of the centromere, as in *Fritillaria lusitanica*[3] and *Fritillaria pyrenaica*[4]; (2) to a close proximity of the nucleolar organizer, which seems to be the case in *Poa alpina*[5] and in *Campanula persicifolia*[6]. There are also other examples where for reasons unknown the centric constrictions appear accentuated, as in *Aconitum*[7] and in *Crocus*[8].

The presence of an extended polyploid series in *Allium neapolitanum* reminds one of the situation described by Levan[9] in *Allium nutans*, where the whole range from $2x$ to $12x$ was found. The fact that three different forms can occur in the same commercial sample of bulbs seems, however, unprecedented. It suggests that this species has a form of versatile reproduction in which either fertilization or meiosis, or both, may be omitted from the normal sexual process.

This investigation was made possible by a scholarship from the State Scholarships Foundation of Greece, to which grateful acknowledgment is made.

A Gene for Eyelids Open at Birth in the House Mouse

In a stock of mice kept by one of us (J. H. B.) there has arisen a mutant gene which in the homozygous condition causes the eyelids to be open at birth. A similar character has been observed in mice by others[1,2]; but this seems to be the first occasion on which it has been found to have a simple genetical basis.

In a normal mouse the eyelids fuse about five days before birth and reopen about nineteen days later. In the abnormal mice described here, there is no pre-natal fusion of the eyelids. One day after birth an inflammatory exudate covers the eye opening; about four days later this falls away and a whitish excrescence may be seen in the superior fornix conjunctivæ. This excrescence gradually decreases in size and has usually disappeared by the eighteenth day after birth. The eye is then smaller than normal. Corneal opacity results but tends to diminish with advancing age.

Table 1. Data from Backcrosses in Coupling for *wa*-1 and *eo*

Sex of heterozygous parent	Offspring				
	wa-1 *eo*	*Wa*-1 *Eo*	*wa*-1 *Eo*	*Wa*-1 *eo*	Total
Female	39, 40	49, 48	4, 1	1, 4	93, 93
Male	54, 47	43, 43	6, 7	4, 2	107, 99

The first figures refer to females, the second to males

The recessive gene wavy-1 (*wa*-1) for wavy coat and vibrissæ was segregating in this stock, and at first the eye abnormality was observed only in *wa*-1 homozygotes. All offspring from matings between *wa*-1 homozygotes with abnormal eyes but none of the offspring from outcrosses of such abnormal *wa*-1 homozygotes had the eye abnormality. Some progeny from these outcrosses were mated together and others were backcrossed to the wavy parent with abnormal eyes. A few wavy mice with normal eyes and some non-wavy mice with abnormal eyes appeared in the next generation. The backcross data (Table 1) which have accumulated from this and later genera-

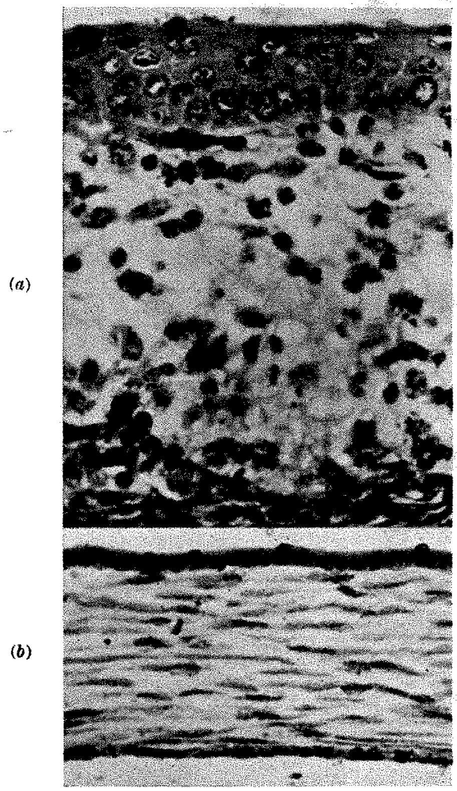

Fig. 1. Section through epithelium overlying the cornea, (*a*) in a four-day old mouse with eyes open at birth, showing œdema and polymorphonuclear infiltration of the substantia propria corneæ with hyperplasia of the external epithelium, and (*b*) in a normal four-day old mouse. (× *c*. 387)

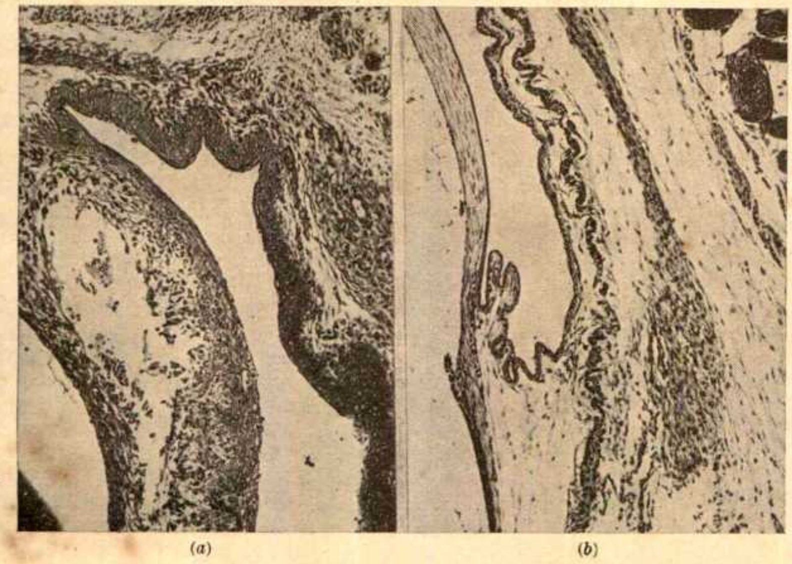

(*a*) (*b*)

Fig. 2. Section through the cornea, (*a*) in a four-day old mouse with eyes open at birth, showing swelling and vesiculation of substantia propria corneæ, and (*b*) in a normal four-day old mouse. (× *c*. 83)

tions seem to indicate that 'eyelids open at birth' is due to a single recessive gene (*eo*) linked with *wa*-1, the recombination frequency being 5·376 ± 1·654 per cent in females and 9·223 ± 2·016 per cent in males. All these data have come from coupling backcrosses. Repulsion backcrosses, which have been set up, have not yet had time to produce offspring. Our estimates of the recombination frequency consequently may be biased because of differential viability. There was no noticeable difference in viability between the normal and affected mice under laboratory conditions; but the mutant homozygote presumably would be at a selective disadvantage in the wild.

More than three hundred mice with eyelids open at birth have now been reared and in all but ten (four females and six males) both eyes were affected. One of these ten mice had an abnormal right eye and the others had abnormal left eyes. In five other mice, the eyelids were open at birth but the conditions described above failed to develop.

Eyes of seventeen- or eighteen-day old embryos from an abnormal-eyed female crossed with a male heterozygous for the eye character were examined histologically. The thirteen embryos were sorted into two groups—those with opaque and those with clear eyes. Coronal sections of their eyes confirmed that the eyelids were open in embryos of the second, but not in those of the first, group. Six abnormal four-day old mice were also examined. The separated eyelids were swollen and purplish-red, and the cornea was visible. The eyes and lids of these mice and of six normal ones were excised and serially sectioned. The corneæ of the affected mice were thickened, the nuclei of the substantia propria were enlarged, and there was an infiltrate of a few polymorphonuclear leucocytes. The overlying epithelium, instead of being a single layer of cuboidal cells (Fig. 1), consisted of three or four layers with a few mitotic figures. The connective tissues of the eyelids were œdematous; but cellular infiltration was not conspicuous (Fig. 2). There was no indication of a conjunctival slough such as has sometimes been said to be associated with this condition[1].

The histological appearances suggest that infection may account for the abnormal post-natal eye conditions. The eyes and lids of several abnormal four-day old mice were therefore excised under sterile conditions, ground, and an extract prepared with a suspension of a sterilized rabbit serum in saline solution. This extract was centrifuged and the supernatant liquid, after it had been mixed with sufficient penicillin and streptomycin to destroy bacteria, was inoculated intraperitoneally into one group of three-day old mice and intracerebrally into another. None of these mice showed signs of disease during the ten days in which they were afterwards observed. The extract was also injected into eleven-day old chick embryos, by the chorioallantoic route in one group, and into the yolk sac in the other, but no growth of virus was detected. Cultures were prepared aerobically and anaerobically from the centrifuged material before the addition of penicillin and streptomycin; but no bacteria were detected.

Sections from the eyes of abnormal ten-day old mice showed œdema of the cornea, especially in its outer part. Polymorphonuclear leucocytes were scanty; and the overlying epithelium had fewer mitotic figures than did that from four-day old mice. In abnormal adult mice the cornea was found to consist of two distinct zones, an outer œdematous zone and an inner compact zone of fibrous tissue.

The histology indicates a mild inflammatory reaction with the subsequent development of corneal fibrosis leading to opacity. The hypothesis that the inflammatory reaction is due to trauma, probably associated with the eyes being open at birth, is supported by the presence of sterile cultures and by the absence of an inflammatory reaction in the corneæ of open-eyed mice *in utero*.

An Adhesive for labelling Animals exposed to Sea-Water over Long Periods

THE adhesive, 3*M EC*-1341, has been found to be successful in attaching paper labels to the valves of experimental oysters which were living in a natural salt pond for eight months.

The method of labelling was as follows.

A small (2 cm. × 2 cm.) smooth area of the oyster's valve was scrubbed clean with a brush, washed with fresh water, then with 80 per cent alcohol, and finally wiped with a dry cloth. Next the oyster was placed either in the sunlight or under a gooseneck lamp for 5–10 min. until the treated area became completely dry. Then the adhesive was applied to the clean, dry surface with a brush. A small (7 mm. × 7 mm.) paper label was placed on this spot and covered with a second application of the adhesive. Again the oyster was set aside to dry, this time for 30 min. or until the sticky fluid became completely dry and hard. The oyster was then placed, with others in the series, in a wire cage which was submerged in the water of a natural salt-pond. When the oysters were examined at the end of an eight-months period all the labels (fifty oysters) were firmly attached and easily readable.

The labels were cut to the desired size from regular filing cards and the appropriate data were marked upon them with a sharp but soft lead pencil.

This method is by far the most successful of any of the various means of labelling which have been tried in the past. First, the labels remain attached for the longest period of time. Secondly, the numbers can be marked on the paper labels with a fine-pointed pencil before the labels are stuck on to the valve. This is a great advantage over using a wax crayon, small paint-brush or pen upon either the surface of the valve itself or upon adhesive tape already adhering to the relatively rough surface of the valve. Furthermore, the second coat of adhesive protects the identification numbers so that they are as easily read after eight months as the day they were written. Their appearance suggested that they would remain in this condition for many more months.

The adhesive 3*M* *EC*-1341 is a liquid which, if it becomes too thick for easy application, can be diluted with acetone. However, the container should be kept closed whenever the adhesive is not being used. The adhesive was kindly given by the Minnesota Mining and Manufacturing Co., 700 Grand Avenue, Ridgefield, New Jersey.

An Interfacial Barrier observed during Liquid–Liquid Extraction of Uranyl Nitrate

Earlier investigations on the transfer of solutes across liquid–liquid interfaces in a stirred cell[1,2] have been extended to a study of the transfer of uranyl nitrate, in both directions, between water and three solvents, dibutyl carbitol, methyl *iso*butylketone (hexone) and tributyl phosphate; the last-named was used as 20 per cent solutions in the inert diluents, 'odourless kerosene', benzene, and carbon tetrachloride. The same apparatus was used as previously described, the two phases, contained in the upper and lower compartments of the transfer cell, being stirred independently. An annular gap between the two compartments enabled the interface to be constrained to a fixed plane of known area. A rigorous study of the hydrodynamics of this transfer cell had already been made[1], so that it was possible to compute the diffusional resistances on each side of the interface for any stirring conditions. The stirring-rates used were sufficiently high for transfer to and from the interface to take place by eddy diffusion, molecular diffusion being negligible.

With the dibutyl carbitol–water and hexone–water systems the observed 'overall' mass-transfer coefficients for transfer in either direction were initially generally either in good agreement with the values calculated assuming the diffusional resistances to be the rate-controlling processes or else somewhat higher. As in the earlier work the higher rates were found to occur in those systems where interfacial turbulence arose[2,3]. These results appear to indicate that initially there is no significant interfacial barrier present. It was found, however, that the rate of transfer fell off markedly during each experiment, eventually reaching values of about a fifth of the initial value. The final slow rate, which in any particular system was substantially independent of concentration, corresponded to an apparent interfacial barrier several times larger than the eddy diffusional resistances. In the case of the dibutyl carbitol–water system experiments were carried out at 50°, as well as 20°; but the final slow rate was independent of temperature. The transfer of uranyl nitrate from water to the tributyl phosphate solutions was also initially controlled by eddy diffusion and the rate fell off as before to a slow final value independent of concentration. With transfer in the reverse direction, however, slow rates corresponding to an interfacial barrier were always obtained.

The reciprocal of the transfer-rate is equivalent to a transfer resistance so that the difference between the reciprocals of the observed and calculated rates gives the value of the additional interfacial resistance. This, of course, is equal to the reciprocal of an interfacial transfer-rate. Typical variations of the resistance with time are shown in Fig. 1.

The transfer of uranyl nitrate between the dibutyl carbitol–water and hexone–water phases has been previously studied by Murdoch and Pratt[4], in a

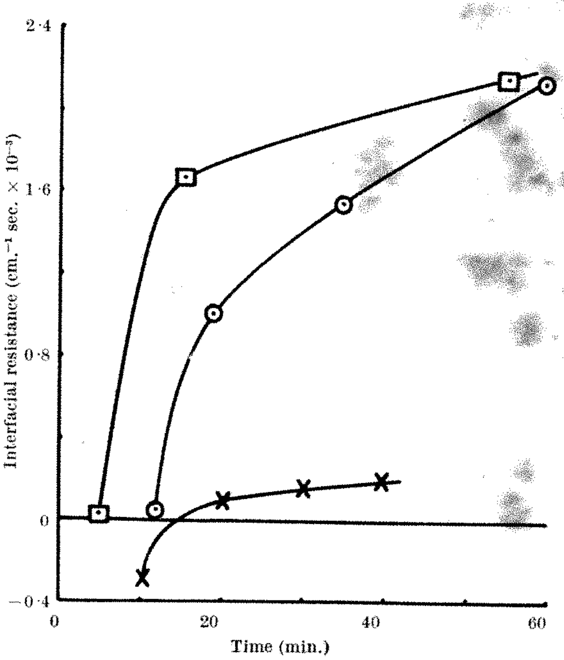

Fig. 1. Increase of interfacial resistance with time: ⊡—⊡—, water → tributyl phosphate/kerosene; ⊙—⊙—, dibutyl carbitol → water; ×—×—, hexone → water (interfacial turbulence)

'wetted wall' column in which the interface was continuously being renewed. An interfacial resistance was shown to be present; but the interfacial transfer coefficients reported were greater than those obtained in this work, for example, about 0·015 cm./sec. as compared with final values of about 0·001 cm./sec. This difference might conceivably be due to the rapid renewal of the interface in the wetted wall column, each element of which is replaced in a few seconds, as compared with the increasing age of the interface in the transfer cell.

A study of the extraction of uranyl nitrate from water into a hydrocarbon solution of tributyl phosphate has recently been carried out by Hahn[5]. Neither phase was stirred, so that transfer to the interface was by molecular diffusion. No interfacial barrier could be detected; but as molecular diffusion is considerably slower than eddy diffusion, a barrier sufficiently large to affect the rate of transfer in stirred systems might be undetectable in Hahn's experiments.

All attempts to provide a theoretical explanation for the fall-off in rate have so far been unsuccessful; however, it has been shown that the effect is real and not due to surface contamination.

I wish to thank Mr. A. S. White for his continued interest in this work and Dr. H. R. C. Pratt for much useful discussion.

Relation between the Volume of a Liquid and its Internal Energy

IN a recent paper[1], Benninga and Scott have pointed out that an adequate theory of liquids must account for the approximate identity, EV = constant. E is defined as being equal to the difference between the internal energy of the substance in the perfect gas state and in the liquid state at a given temperature, and will be identified with the potential energy between the molecules: V is the molar volume of the liquid. We wish to point out that this relationship can be made a direct consequence of the simplest form of 'hole' theory. Although only the case of spherical molecules of a single species will be considered here, it is intended that a treatment generalized to include the case of mixtures of non-spherical molecules will be published elsewhere in the near future.

Although the molecules in the liquid state do not in general display long-range order, 'short-range' order is known to exist: thus there is a fairly clearly defined distance l between the centres of molecules which are nearest neighbours. The expansion of such a liquid with change of temperature or pressure can be considered from two extreme points of view: either the distance between all the molecules may alter, resulting in a uniform stretching of the whole liquid structure, or the distance l may remain constant and vacant sites may appear in the ring of nearest neighbours surrounding each molecule. The former theory—uniform stretching—leads, on the basis of a Lennard-Jones 6–12 intermolecular potential, to the law[2] EV^2 = constant. In order to investigate the implications of the second theory, two simplifying assumptions will be made: (*a*) that the vacant sites are randomly distributed throughout the body of the liquid; (*b*) that the vacant sites (or 'holes') are equal in size to a molecule.

Let there be h such sites and N molecules, and let e be the interaction energy due to each pair of molecules which are nearest neighbours. Longer-range interactions will be neglected. Then

$E = \frac{1}{2}NZe \times$ (proportion of nearest neighbour sites which are occupied by molecules)

$$= \tfrac{1}{2}NZeN/(N + h)$$
$$= \tfrac{1}{2}NZeV'/V$$

where V' is the molar volume of the hole-free lattice, and V is the molar volume of the liquid.

Thus this method of expansion leads to the required relationship $EV = \frac{1}{2}NZeV'$ = constant.

Production of Carrier-free Cobalt-58 by Pile Irradiation of Nickel

IN the course of a study of neutron–proton reactions in the Harwell pile, we have irradiated nickel metal both in the ordinary irradiation facilities and in a hollow uranium bar. In this bar the energies of the fast neutrons available approximate to the spectrum of fission-neutron energies.

The yields of cobalt-58 obtained are shown in Table 1; the fast-neutron fluxes were measured by counting phosphorus-32 formed in sulphur monitors irradiated at the same time as the nickel, assuming a cross-section of 0·03 barn, as given by Hughes[1], for the reaction sulphur-32 (n,p) phosphorus-32.

We have separated cobalt-58 from irradiated nickel in a carrier-free state, obtaining about 80 per cent yield. The nickel was dissolved in nitric acid, the solution evaporated to dryness, and the residue taken up in 9 N hydrochloric acid. This solution was added to a column of 'De Acidite FF' anion-exchange resin, when the nickel passed through and the cobalt was adsorbed. When all the nickel had been removed

Table 1

Irradiation	Fission neutron flux (neutrons/cm.^{2}/sec.) ($S(n,p)$ ^{32}P monitors)	Saturation activity (mc./gm. Ni)	Cross-section (Ni-58) (millibarns)	Cross-section (Ni metal) (millibarns)
Hollow slug, 9 days	4·9 × 10^{11}	4·4	47	31·5
Thermal flux, 1·4 × 10^{12} (n/cm.^{2}/sec.), 6·4 days	2·7 × 10^{11}	2·3	45	31
Thermal flux, 1·2 × 10^{12} (n/cm.^{2}/sec.), 6·4 days	2·3 × 10^{11}	1·9	44	30
Thermal flux, 1·0 × 10^{12} (n/cm.^{2}/sec.), 6·4 days	2·0 × 10^{11}	1·7	44	30

with more 9 *N* hydrochloric acid, the cobalt was eluted with water and dilute ammonia[2].

From 5 gm. of spectroscopically pure nickel irradiated for eighteen months a solution of cobalt-58 was obtained with the following characteristics, extrapolated back to the end of irradiation (assuming a half-life for cobalt-58 of 70 days).

Activity = 33·6 millicuries
Volume = 50 ml.
Nickel concentration = $<0·2$ p.p.m. of solution
Cobalt concentration = $<0·4$ p.p.m. of solution
Specific activity = $\geqslant 1,680$ curies/gm. cobalt

The cobalt concentration was below the lower limit of the spectrographic and spectrophotometric methods used for its determination. In this specimen of cobalt-58 there was present 0·06 per cent cobalt-60 at the end of irradiation; as the maximum estimated cobalt in the solution would produce only 0·03 per cent cobalt-60 by (n,γ) reaction, 0·03 per cent at least must be due to the reaction nickel-60 (n,p) cobalt-60. This gives a cross-section for this reaction of between 3 and 7 millibarns.

No other radiochemical impurities have been found in the cobalt-58, either by $\beta +$ absorption in aluminium, rate of decay, or by examination with a γ-scintillation spectrometer.

The cross-section for fission neutrons of 47 m.barns for the reaction nickel-58 (n,p) cobalt-58 is the highest recorded for a reaction of this type, the next highest being that of sulphur-32 (n,p) phosphorus-32 at 30 mb. It is about four times the cross-section calculated from consideration of mass differences and proton penetrability in the way described by Hughes[3].

An absolute determination of the radioactivity of one cobalt-58 solution was obtained by coincidence measurements and by counting positrons in a 4π Geiger counter, the source being covered with 260 μgm./cm.^{2} of aluminium to cut out Auger electrons. A branching ratio of 15 per cent for positrons was assumed, and an accuracy claimed of ± 5 per cent. Other cobalt-58 solutions were referred to this one by comparing peak heights obtained for the 0·81 MeV. γ-ray on a γ-scintillation spectrometer.

We should like to thank Dr. R. A. Allen, of the Physics Group of the Isotope Division, for providing a standard phosphorus-32 solution, and for standardizing a cobalt-58 solution, and Mr. F. Birks for spectrographic analysis of our cobalt-58 solution.

Ca II Emission Lines in the Twilight Spectrum

Spectra obtained at Saskatoon during the summer of 1955 showed sharp emission lines of wave-lengths 3933·8 A. and 3968·4 A. ± 0·2 A. to be present at times in the twilight. The spectra were obtained with two Schmidt spectrographs of dispersion 20 A./mm. and 10 A./mm. A microphotometer tracing of a twilight plate obtained on July 14 is shown in Fig. 1.

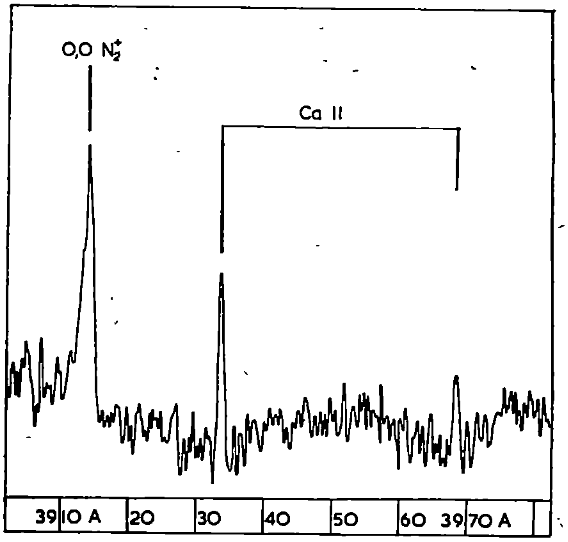

Fig. 1. Microphotometer tracing of twilight spectrum obtained July 14, 1955

The wave-lengths of the *H* and *K* lines of ionized calcium are 3933·7 A. and 3968·5 A. Comparison of the measured wave-lengths with the "M.I.T. Wave-length Tables"[1] showed that no other element besides Ca II could give rise to both emission lines. A measured intensity ratio of 2·1 ± 0·5 is consistent with the identification with Ca II. The theoretical intensity ratio in the absence of self-absorption for a non-selective excitation process is 2. For a resonance excitation process due to sunlight, as is suggested below, the ratio will be reduced slightly since there will be less energy available in the solar continuum at the wave-length of the stronger line than at that of the weaker. The variation in the intensity of the solar continuum is, of course, due to the *H* and *K* Fraunhofer absorption lines.

The twilight spectra were obtained by directing the 'line of sight' of the spectrograph so that it intersected the boundary between the illuminated and dark regions of the atmosphere at a constant height of 100 km. (neglecting atmospheric refraction). Exposures of three hours or more in one night are possible at Saskatoon in midsummer. The altitude and azimuth of the line of sight must, of course, be varied continuously according to a precalculated programme. The zenith angle varied from 30° to 85°.

It was found that the emission was not present with constant intensity. A continuous programme of observation was therefore carried out from early July until December. The results of this series of spectra

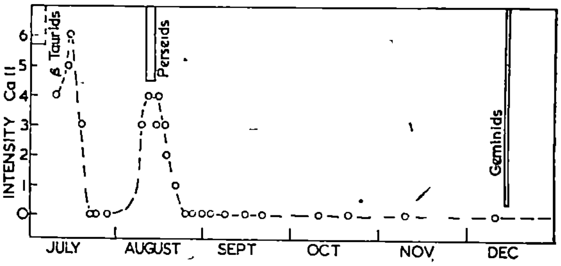

Fig. 2. Eye estimates of the intensity of Ca II lines in the twilight spectrum obtained during months of July–December, 1955. The times of the principal meteor showers occurring during this period are indicated in the upper part of the graph

are shown graphically in Fig. 2. Each point represents a satisfactorily exposed plate. Most of the later plates were exposed for two or more days; the median date is indicated. It will be noticed that the emission lines disappeared by the end of July but reappeared strongly about August 9–10. The intensity then decayed steadily over a period of about ten days; no further reappearance of the line was detected.

While the lines were observable, two exposures were programmed for a height of 80 km. and two for a height of 120 km. No emission was detected for the 80 km. spectra whereas the plates for 120 km. showed the lines with measurable intensity. There is thus some evidence for supposing that the emission may be concentrated in the region 100–120 km.

The question as to whether or not the emission is primarily a twilight phenomenon was investigated by exposing five plates to the morning and evening twilight for one half of the slit and to the night sky (and aurora) for the other half of the slit. Two of these plates obtained over the period August 11–12 showed the Ca II emission lines to be present also in the night sky and aurora; indeed, the emission was stronger in the latter section of the plate. In the case of these two plates it is not possible to be sure whether the emission was really associated with the night sky or aurora. The spectrograph which was directed towards the lower part of the northern sky may have received some residual twilight radiation from higher atmospheric levels or may even have recorded the Ca II lines emitted directly from meteor trails. However, in the three other plates obtained during the period of declining activity in August, the lines were observed only in the twilight and were absent in the night sky and aurora.

The most reasonable interpretation of the above results is that the observed emission is due to a resonant excitation of the calcium ions by sunlight analogous to the well-known twilight spectrum of sodium. The intermittent appearance of the emission would possibly suggest that the calcium was of meteoric origin. In Fig. 2, the dates of the principal meteor showers are indicated[2]. There is a striking correlation between the August reappearance of the calcium emission and the Perseid meteor shower. The earlier appearance of the emission may have been connected with the day-time meteor activity occurring in June and early July. Further observations planned for the coming summer should enable a definite decision to be reached on this point. The failure to observe any twilight emission in December at the time of the Geminid meteor shower is not very significant since no exposures were obtained between December 7 and December 18, whereas the meteor shower has its maximum intensity about December 13–14.

The heights quoted above are derived from calculations of the position of the shadow of the surface of the Earth neglecting the effect of the atmosphere. Two corrections must be made to these results. The first is that due to atmospheric refraction which tends to lower the shadow boundary by 20–30 km. The second correction is that due to the high extinction coefficient of the lower regions of the atmosphere for radiation of wave-length 4000 A.; as a consequence of this effect some higher level of the atmosphere rather than the surface becomes effective in casting the shadow. The latter effect consequently tends to raise the effective shadow height. It is quite likely that in this case these two corrections may cancel one another.

The maximum absolute surface brightness, B, of the stronger line referred to the zenith was estimated provisionally to lie between $0 \cdot 4$ and $2 \cdot 4 \times 10^6$ photons cm.$^{-2}$ sec.$^{-1}$ steradian^{-1}. In terms of the recently proposed new unit, the rayleigh[3], this brightness corresponds to a value of $4\pi B$ between 5 and 30 rayleighs. An extinction coefficient of $0 \cdot 10$ km.$^{-1}$ was taken for the atmosphere at 4000 A., following the results of Baum and Dunkelman[5].

I am indebted to Dr. D. M. Hunten for valuable discussions on the subject of twilight spectra.

Sudden Absorption of Atmospherics due to Increase in Cosmic Ray Intensity

An effect of the solar flare and cosmic ray increase of February 23 reported by several observers[1–4] was recorded on the atmospheric noise study apparatus located at the U.S. Air Force Cambridge Research Center site at Fourth Cliff, in Scituate, Mass.

The sudden absorption of energy that occurred is of interest because it was recorded during the night. The night-time absorption appears to be directly related to the cosmic ray increase.

The apparatus consisted of a whip antenna feeding a receiver, set at a frequency of 49 kc./s. The output of the intermediate-frequency amplifier was fed into a probability computer designed and built by the University of Florida. A milliammeter recorded the percentage of time that the electric field intensity exceeded the threshold voltage set on the computer. The level on the accompanying illustration is such that an input of 2 µV. exceeds the threshold voltage 50 per cent of the time when the chart time reads at the middle of the scale. The time constant of the unit was 16 sec.

Fig. 1 illustrates the absorption of signal taking place at approximately the time of observation of the

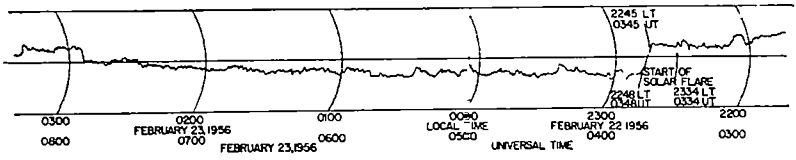

Fig. 1

flare. The exact sequence of time was as follows: The flare was observed in Tokyo at 0334 U.T. February 23. At 0340 U.T. an S.I.D. was reported. The drop in signal-level of the 49 kc./s. atmospherics started at 0344, a few minutes earlier than the beginning of the cosmic ray increase noted at 0348 at Cheltenham, 0350·3 at Chicago, and 0353 at Godhavn, Greenland. At 0343 Pierce and Moritz[4] observed at Cambridge, Mass., an increase in the rate of change of phase of 16 kc./s. signals from Rugby, England.

The time lapse involved between the S.I.D. and the sudden absorption of atmospherics (4 min.) and the fact that the event occurred at 2244 local time seems to indicate that the disturbance observed was produced by the cosmic ray increase rather than being connected with the S.I.D. produced by the ultra-violet. Considering the geometry of the situation it seems unlikely that the decrease in signal-level was due to the increase in absorption of atmospherics in the sunlit portion of the globe, because observations were made around the period of local midnight.

The signal intensity decreased to its daylight value within the period of 5 minutes. It returned to its pre-absorption level at 0830 U.T. or 0330 L.T. At this time the Cheltenham and Godhavn cosmic ray increases were down to about the same level as their pre-flare value, while the Chicago amplitude had declined to approximately 200 per cent of its pre-flare level (it had increased by a factor of eighteen times). The time of onset of the sudden absorption and the rise to pre-flare value of the 49 kc./s. signal-level both indicate a close correlation with the sudden increase in cosmic ray intensity on the dark side of the Earth.

Considering the path taken by the cosmic ray particles and the ionization produced, it might be of interest to consider the role of the steady-state particles in producing the night-time ionosphere.

Representation of the Inelastic Deformation of Concrete by means of a Mechanical Model

THE non-linearity of the relation between the stress and the strain of concrete at high loads was observed by many of the early workers in the field of reinforced concrete research at the turn of the century. It is, however, doubtful whether the difference between non-linear elasticity and inelastic behaviour was fully recognized at that time. Glanville's experiments[1] established the existence of partially reversible inelastic strains, occurring at the lowest loads, which are for all practical purposes directly proportional to the concrete stress. These inelastic strains, usually referred to as creep, are consequently a viscous phenomenon, and rheological models have been constructed[2-4] to describe the visco-elastic deformation of concrete. Models of this type have satisfactorily explained the deformation of concrete subject to moderate loads over long periods of time; however, they fail to account for the observed relation between stress and strain in concrete tested to destruction at a constant rate of strain. Since 1938 stress–strain diagrams obtained from individual test pieces have been reported from time to time, which show a descending portion terminating at a relatively high ultimate strain. Both phenomena have now been confirmed by a systematic investigation[5].

Freudenthal[6] has suggested that the departure of the concrete stress–strain diagram from visco-elastic behaviour is due to breakdown of the adhesion between the cement and the aggregate. This is confirmed by the observation of minute cracks at about 60 per cent of the ultimate load by Berg[7] using an optical method, and by Jones[8] using an ultrasonic method; the presence of micro-cracks has also been inferred from tensile tests by Blakey and Beresford[9]. These considerations lead to the statistical concept of a concrete specimen made up of a number of elements with strengths distributed over a specific range. Williams and Kloot[10], working on the behaviour of timber specimens in tension, have produced a mathematical theory for a model of this type.

The mechanical model shown in Fig. 1 has been devised to reproduce the various features of the elastic and inelastic deformation of concrete referred to. It consists of two series of viscous dashpots and elastic springs in parallel, the dashpot of one of the units being blocked by non-return valves; and a series of brittle springs in parallel which behave elastically up to failure, the failing loads of these springs being distributed over a range. When this model is deformed by a moderate load, so that the brittle springs are not damaged, it exhibits an immediate elastic deformation proportional to the applied load, and a progressive inelastic deformation at a decreasing rate, the total inelastic deformation over an infinite period being proportional to the applied load. When the model is unloaded the procedure is reversed; but due to the blocking of the second dashpot some of the inelastic deformation is not recovered. When the model is loaded sufficiently rapidly to produce negligible deformation of the dashpots, it deforms elastically until the fracturing load of the weakest brittle spring is reached, and the subsequent inelastic deformation is irreversible. A typical load-deformation diagram of a model under these conditions is shown in Fig. 2, and this is very similar to the experimental stress–strain diagrams for concrete tested rapidly at a constant rate of strain which have been referred to. When the model is deformed sufficiently slowly to allow for appreciable deformation of the dashpots, and the load is carried

Fig. 1. Comprehensive mechanical model for the elastic and inelastic deformation of concrete

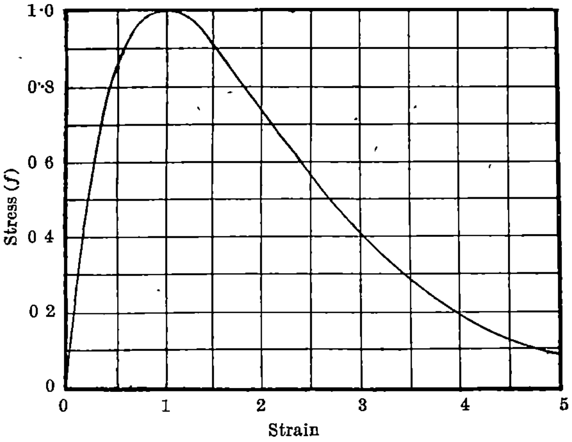

Fig. 2. Load-deformation curve produced by the mechanical model in Fig. 1 when it is deformed sufficiently rapidly to produce negligible viscous deformation (Expressed in terms of the maximum stress and strain)

at the same time above the fracturing load of the weaker brittle springs, then both types of inelastic deformation are reproduced.

Apart from the quantitative determination of the inelastic deformation of concrete, the model may assist the qualitative examination of the long-term behaviour of concrete under load. The recent successful application of the theory of plasticity to structural steel design has focused attention on the development of a similar theory for reinforced concrete structures. The plastic deformation of steel, like the viscous deformation of concrete, does not constitute structural damage although it results in permanent and frequently serious distortion of the structure. The deformation of concrete at high loads due to the formation of micro-cracks, on the other hand, results in structural damage which can be repaired only by chemical action over long periods. It has been established that stress relation due to creep over long periods increases the capacity of redundant structures to carry sustained working loads. Furthermore, the high inelastic strains due to micro-crack formation increase the load-bearing capacity in a continuous test to destruction. It cannot, however, be assumed that inelastic deformation increases the load-bearing capacity of a reinforced concrete structure for all combinations and sequences of loading.

Creep in Coal at Room Temperature

THE deflexion of a cantilever of a bituminous coal (Barnsley Hards) has been found to increase steadily with time under a constant load well below the rupture value. This movement is taken to be evidence of the phenomenon known as creep.

A typical graph showing the relationship between the deflexion of a cantilever of Barnsley Hards and the duration of loading is shown in Fig. 1. The deflexion d satisfies an equation of the form:

$$d = A + B \log t + Ct$$

where t is the duration of loading. This is similar in form to the equation used by Griggs[1] to represent the deformation of a cube of rock subjected to uniaxial compression.

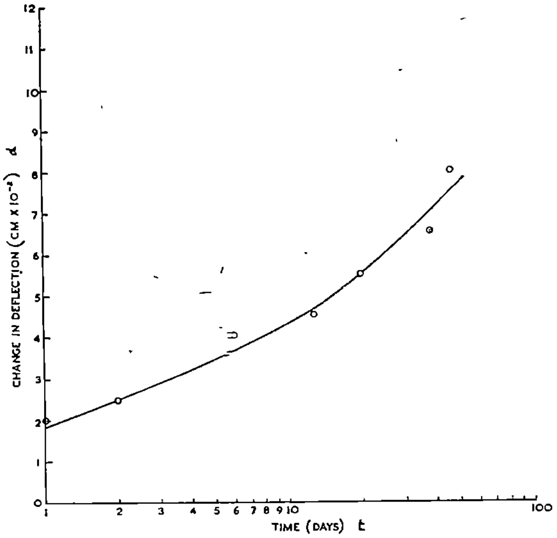

Fig. 1. Change of deflexion with time of a loaded cantilever of Barnsley Hards. Curve gives $d = 1{\cdot}95 + 1{\cdot}82 \log t + 0{\cdot}051\, t$. Specimen dimensions (cm.): width, 1·62; thickness, 0·24; unsupported length of cantilever, 8·5. Applied load, 31·4 gm. $\eta_c = 1{\cdot}81 \times 10^{16}$ poises

In like manner, the recovery of the cantilever when unloaded satisfies the equation:

$$d = A + B_1 \log t$$

used by Griggs for the recovery of cubes. The logarithmic term can be interpreted as a pseudo-elastic or recoverable creep and the linear term Ct as a pseudo-viscous creep. Using this subdivision, the creep viscosity η_c of Barnsley Hards coal at room temperature has been estimated to be of the order of 10^{16}–10^{17} poises, compared with 10^{20}–10^{22} poises obtained by Griggs for limestone. This comparison may not be strictly valid, since Griggs obtained his results from compression tests.

In similar experiments at the same sensitivity of observation, no creep of anthracite was observed.

Although Barnsley Hards and anthracite have closely similar compressive strengths across the bedding planes (about 8,000 lb./in.^{2} for 1-in. cubes), they are easily distinguishable by the manner in which they break. Anthracite breaks into conchoidal fragments which frequently have razor-sharp edges, whereas the Barnsley coal breaks into more regularly shaped pieces with less acute edges. In general, cubes of both coals break explosively when they are compressed between flat platens; but it has been found possible to induce non-explosive breakage in the Barnsley coal provided extremely low rates of straining are used. No matter how slowly the anthracite cubes have been loaded, explosive breakage has always occurred. These differences are probably related to the rheological properties of the coals, and in particular to the presence or absence of creep.

Somewhat analogous to the explosive breakage of cubes are the violent outbursts of coal from the seam which occasionally occur. These outbursts have occurred in many areas, but there is strong evidence that in the United Kingdom they are most prevalent in the anthracite areas. Outbursts have been attributed to many factors, but high in importance among these would seem to be the nature of the coal itself. If the coal can creep, the roof load will be more easily accommodated as the workings advance, so that the stresses in the coal remain below the breaking strength. If the coal cannot creep, there is a greater risk that the breaking strength of the coal will be exceeded, resulting in an explosive outburst. This may offer an explanation of the prevalence of outbursts in anthracite; but it would be unwise to generalize further since other considerations, such as the nature of the floor, the thickness of the seam and the rate of build-up of the overburden stresses all affect the problem.

Photographic Sensitizers in Gelatin

Thirty years ago, Sheppard[1] isolated allyl *iso*thiocyanate from extracts of photographically active gelatins. It has since been made evident that this sulphur sensitizer is not usually present in gelatins produced by existing methods. Steigmann[2] has demonstrated by chemical tests the presence in lime-treated hide gelatins of thiosulphate and trithionate ions, and has indicated a mode of formation of these sensitizing substances by alkaline degradation of cystine. Wood[3,4] has applied paper chromatography and paper electrophoresis to extracts from gelatins, and has detected thiosulphate and polythionates. He has suggested alternative mechanisms of sensitizer formation, including oxidation of sulphides used for depilatory purposes in gelatin precursor treatment, and also oxidation or autoxidation of sulphur dioxide. The purpose of the present communication is to indicate that a quantitative method has been devised for determining sensitizers in gelatin extracts.

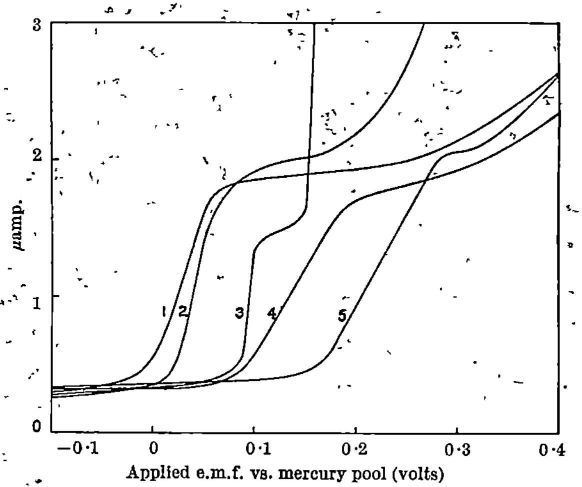

Fig. 1. Anodic polarograms of various sulphur sensitizers in 0·2 *M* potassium nitrate: (1) 0·4 m*M* Thiosulphate. (2) Gelatin extract. (3) 4 m*M* Allyl *iso*thiocyanate. (4) 0·5 m*M* Thiourea. (5) 0·5 m*M* Thiosinamine

The method of extraction was similar to that used by Wood[3], but on a smaller scale; 25 gm. of the gelatin were extracted at 0° C. with a total of about 200 ml. of water, and the extracts were concentrated *in vacuo* to 10 ml. These concentrated extracts have been examined polarographically. Fig. 1 shows the results of anodic polarography in 0·2 *M* potassium nitrate on the extract from a particular gelatin and on some known sensitizers. In making such comparisons, it is essential to compare at roughly the same wave-height, as the substances shown all have a half-wave potential which varies with concentration.

It will be seen that the sensitizer present closely resembles thiosulphate in its behaviour. Cathodically, in 1 *M* ammonium dihydrogen phosphate[5], tetrathionate has been detected in the extract. Apart from their polarographic characteristics, the identification of these constituents is confirmed by the behaviour of the extracts towards anion-exchange resins, and to such reagents as iodine (for the thiosulphate) and sulphite (for the tetrathionate).

This technique is readily applicable to the routine examination of gelatins. In this Laboratory, fifty-two gelatins have been examined in this way, and the conclusions indicated above have been found to be generally valid. Neglecting for the moment the tetrathionate content as of secondary importance[4], the thiosulphate contents of the gelatins tested range from 34 p.p.m. for a very active hide gelatin to 0 for inert gelatins. In general, the thiosulphate contents correlate well with the photographic activities of the gelatins.

This work will be reported in full elsewhere. Thanks are due to the directors of Ilford Limited for permission to publish this communication.

G. Russell

Chemical Research Laboratory,
Ilford Limited,
Brentwood, Essex.

Feb. 13.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Chemists and Physicists (with university degrees) in the Laboratories at Watson House, Fulham, London, S.W.6, to undertake research work on the utilization and design of domestic and industrial gas and coke appliances, particularly on cookers, water heaters, gas and coke fires, refrigerators and industrial apparatus—The Staff Controller, North Thames Gas Board, 30 Kensington Church Street, London, W.8, quoting Ref. No. 666/280 (August 9).

Assistant Lecturer in Chemistry—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (August 10).

Assistant Lecturer (preferably with an interest in applied mathematics) in the Department of Mathematics—The Secretary, University College, Gower Street, London, W C.1 (August 10).

Senior Lecturer (with a good honours degree and industrial and teaching experience) to teach Electrical Engineering and Electronics to at least Higher National Certificate standard—The Principal, College of Electronics, Radar Research Establishment, Ministry of Supply, Great Malvern, Worcestershire (August 10).

Assistant Experimental Officer (with a pass degree or at least G.C.E. at advanced level) in the Chemistry Section—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (August 11).

Assistant (graduate in chemistry or biochemistry) in Agricultural Chemistry—The Secretary of the University Court, The University, Glasgow (August 18).

Lecturers (with industrial experience, preferably teaching experience and a special knowledge of one of the following fields: electrical machinery; servos and automatic control; vibration analysis and engineering acoustics; communications (other than radio) in Electrical Engineering—The Secretary of the University Court, The University, Glasgow (August 18).

Leverhulme Senior Research Fellow (graduate in biochemistry or physiology and preferably experience with bio-assay or radioisotope techniques) to work on the effects of steroid hormones in ruminants, and in particular to investigate the physiological bases for the improvement in growth-rate resulting from hormone treatment—The Registrar, The University, Nottingham (August 18).

Lecturer or Assistant Lecturer (with special interests in inorganic or physical chemistry) in Chemistry—The Registrar, The University, Sheffield (August 20).

Research Officer (with a university honours degree in science, with biochemistry, chemistry or physical chemistry as a major subject, or equivalent qualifications, and preferably some research experience) in the Dairy Research Section, Commonwealth Scientific and Industrial Research Organization, Highett, Melbourne—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 410/54 (August 20).

Assistant Lecturer (Grade III) or Demonstrator in Physiology (Chemical Physiology)—The Registrar and Secretary, The University, Bristol (August 25).

Lecturer/Senior Lecturer in Geology at the University of Sydney, Australia, The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 25).

Principal (with a degree in engineering or equivalent, and industrial and teaching experience) with the Gold Coast Local Civil Service, to take charge of a Technical Institute—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD. 114/13/01 (August 30).

Assistant Lecturer in the Department of Philosophy—The Registrar, University College of Wales, Aberystwyth (August 31).

Chair of Botany at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 31).

Chair of Chemical Engineering at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (August 31).

Lecturer in the Department of Geology at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth 36 Gordon Square, London, W C.1 (August 31).

Lecturer (with interest and experience in biophysics) in Physiology—The Secretary, The University, Aberdeen (August 31).

Lecturers (2) in Zoology; a Lecturer in Geography; a Lecturer in Applied Mathematics; a Senior Lecturer in Education; and Chair of Education, at the University of Natal, South Africa—The Secretary. Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31)

Lecturer on the staff of the Department of Physics, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (September 1).

Lecturer (preferably with research interests and experience in the physics of solids) in the Department of Physics, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (September 1).

Reader in Mathematical Analysis at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 15).

Senior Lecturer, and a Lecturer in the Department of Psychology, Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 15).

Lecturer in Logic and Metaphysics at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Cape Town, September 21).

Professor and Head (with high academic qualifications, and wide experience in research, teaching and industrial processes) of the Department of Metallurgy—The Registrar, Indian Institute of Science, Bangalore, India (September 23).

Lecturer or Assistant Lecturer in Mathematics at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 24).

Chair of Mechanical Engineering at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 29).

Chair of Agriculture at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (September 30).

Analyst (with a university degree in chemistry or equivalent qualification in analytical chemistry, for example, A.R.I C., with two years research experience in pure or applied chemistry) in the Department of Agriculture Federation of Nigeria, to carry out analysis and testing of soils and plant materials in connexion with the research programme of a Soils and Crop Nutrition Team, and to supervise the routine work in the Chemistry Laboratory—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD. 63/14/037.

Assistant Warden (with an honours degree in botany, coupled with a general interest in field subjects) at Malham Tarn Field Centre, Near Settle, Yorks—The Secretary and Treasurer, Field Studies Council, Balfour House, 119/125 Finsbury Pavement, London, E.C.2

Cytologist (graduate in zoology with an interest in cytology) in the Cytogenetics Group—The Director, Medical Research Council Radiobiological Research Unit, Atomic Energy Research Establishment, Harwell, Berks.

Demonstrators in Physics; and Research Assistants in Physics to work on the magnetic properties of molybdenum permalloy and on the properties of adamantine compounds—The Registrar, The University, Nottingham.

Lecturer or Assistant Lecturer in Physical Chemistry—The Registrar, The University, Nottingham.

Principal Research Officer (with a university honours degree in natural science, postgraduate research experience and an aptitude for directing investigational work) in the Department of Agriculture, Federation of Nigeria, to supervise rice research work at the Federal Rice Research Station, and to undertake his own research project—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/14/016.

Research Assistant (honours graduate in chemistry) in the School of Chemistry—The Registrar, College of Technology and Commerce, The Newarke, Leicester

Senior Lecturer (preferably with high qualifications and considerable research. industrial or teaching experience, and the ability to develop some branch of applied physics) in Physics—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex.

Technical Abstractor (with a degree in chemistry, experience in the preparation of informative abstracts and literature surveys, and ability to translate scientific German) in the Intelligence Section—The Intelligence Officer, Coal Tar Research Association, Oxford Road, Gomersal, near Leeds.

VACUUM DEPOSITION OF THIN FILMS

by

L. Holland

(Head of the Vacuum Coating Research Laboratory, Edwards High Vacuum Ltd.)

Foreword by

PROFESSOR S. TOLANSKY, F.R.S.

Size. 9″ × 5¾″ 560 *pages* 164 *figures* 25 *plates* 70*s. net*

In spite of the advances which have been made in the development of thin film technology, no comprehensive work exists, dealing with both deposition procedures and the physical properties of thin films, which can serve both as a reference book and guide to the interested worker. Mr. Holland here attempts to fill the need for such a book. As Professor Tolansky says in his foreword: "There is in fact a crying need for an adequate summary of technical procedures such as has been gathered here."

GENERAL RELATIVITY AND COSMOLOGY

by

G. C. McVittie, O.B.E., PH.D., M.A.

(Professor of Astronomy, University of Illinois)

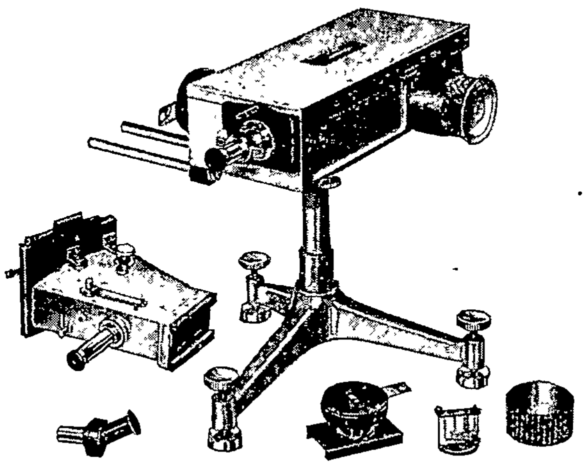
Size · 10″ × 6″ 208 *pages* *Illustrated* 42*s. net*

This is the fourth volume in the International Astrophysics Series. The first five chapters contain an account of the basic theory of relativity and its application to the gravitational field of the sun, and the rest of the work deals with gas dynamics and cosmology.

37 ESSEX STREET, LONDON, W.C.2

PRECISION INSTRUMENTS

Direct Reading Wavelength Spectrometer



for use in the visible spectrum and also, when required, in the ultra violet and infra red. Reading in wavelengths directly.

A camera attachment can be supplied giving the following length of spectrograms :

With quartz prism, wavelength 10,000 A. to 2,200 A., 70 mm.

With glass prism, wavelength 10,000 A. to 3,600 A., 125 mm.

A large range of accessories can be supplied with this spectrometer making it a really universal instrument, and our staff will at all times be pleased to recommend the equipment most likely to meet special requirements.

SCIENTIFIC AND ENGINEERING MAN-POWER IN THE UNITED STATES

AT a Sigma Xi meeting of the American Association for the Advancement of Science in December 1955, Dr. James R. Killian, jun., president of the Massachusetts Institute of Technology, outlined the strategy for augmenting the scientific and engineering man-power resources of the United States (*Amer. Sci.*, April 1956).

The nature of the present dearth of scientists and engineers, he said, is not simply a shortage of men. First and basically, it is a shortage of intellectual talent adequately educated and in the right place. Second, it is more a shortage of specific talents and skills adaptable to specific areas than a general shortage of numbers.

The shortage of high talent is aggravated by the fact that too many young people of exceptional intellectual ability drop out of the educational system before they have achieved an education which fully exploits their abilities. Of the ablest 50 per cent of high-school graduates, only about a third take degrees at college. Too many of the ablest youth of America fail to get the kind of education their abilities deserve. Without dropping standards, only a limited increase in college population can be achieved by stepping up the percentage of high-school graduates who go to college. These conclusions stress the importance of motivating and using more of the exceptional talent and directing attention to its conservation and cultivation.

The American nation would be better served, in Dr. Killian's opinion, by augmenting the total pool of exceptional talent so that all professions benefit, rather than by giving exclusive attention to science and engineering, even though the need for man-power in these fields is at the present time the most urgent. If an attempt is made to build up science and engineering through methods which apparently deprive other professions of talent, it may generate undesirable reactions and side-effects inimical to the welfare of science in the long run. It may also attract into science too many whose talents and predilections are more compatible with other kinds of careers and who would therefore become indifferent scientists and engineers.

Any grand strategy for augmenting scientific man-power must be related to a concerted effort to identify, encourage and more fully educate the top talent among youth.

Considerations of quality show that employers are not looking merely for university degrees; they are looking with a critical eye for very special qualifications—for a sound education in fundamentals, for analytical power, for a grasp of the new and advanced fields of technology. They are looking less for specialized competence at the first-degree level and more for men who have the versatility to follow successfully any one of several specialties.

These special demands indicate a great shortage of young engineers with a mastery of engineering science and thus a competence to handle new, advancing technologies, such as data processing, internal and external aerodynamics, energy conversion, communications, servo-mechanisms, 'molecular engineering' and solid-state physics for the design of materials, and similar functional components of technology.

Thus industry and government are pressing the colleges for engineers of more advanced education and analytical powers. They are looking for men with a fundamental, integrated education in science, engineering and the humanities, rather than for men specialized in some field of technology at the expense of fundamentals.

In the basic sciences the most pressing needs are for those scientists who have the imagination and trained creative power to make the discoveries and generate the new concepts which advance science.

Despite the critical shortage in the rank and file of good competent scientists and engineers, the really acute shortage is now in the 'flag-officer' group.

In the secondary schools the first requirement is to fill in the depleted ranks of science teachers and to do this, not with culls from other fields, but with teachers possessing a grasp of science and the perception to identify and stimulate young people with the bent and capacity for science.

There is the need for earlier identification of scientific talent and for more rigour, more emphasis on excellence in the secondary school. Much of the flight from science at the secondary school-level has resulted from the fear of science as a difficult subject of study.

Blame for this aversion to rigorous thinking rests with parents even more than it does with the schools. "The United States has hitherto displayed an attitude of condescension toward hard intellectual labour in our schools." The survival of the United States requires that the American people attach a higher value to the hard labour of rigorous thought.

The high-school programme should also be flexible, so that an early election of programme does not commit a boy or girl irrevocably to some prematurely selected career or educational programme.

Although the education of the future scientists and engineers has been neglected with effects endangering the nation, the education of other kinds of people is also important. No group of young people should be neglected in order to strengthen another. Secondary schools play a major part in maintaining the fluid, classless society of the United States. Methods for strengthening science teaching and increasing the numbers of scientists will not result in unfortunate distortion of this broader function of the secondary school programme. The highest priorities should be given to better provision for intellectually gifted young people, greater stress on the more rigorous teaching of intellectual skills, and on higher standards of excellence for both teachers and pupils.

At the college-level there are many opportunities available for strengthening scientific and engineering education. The liberal arts colleges are the principal sources of candidates for graduate schools of science. The Wesleyan study and others have shown how remarkable has been the success of a number of small liberal arts colleges in preparing men and women to become distinguished specialists in science.

The needs of the colleges for science teachers is as serious as in the schools, and particularly in those institutions where little research is done; industry and other agencies have drawn the promising young material away by providing opportunities to do research and development and by higher compensation. More grants and fellowships should be given to enable professors of science in liberal arts colleges to have time off from teaching to do research or to have first-hand contacts with creative work in science in the universities or in industrial or government laboratories.

The professional schools of science and engineering have suffered in the competition for top-flight men. The engineering schools are especially vulnerable because their young and imaginative graduates and teachers—especially those in the advancing, growing fields of technology—are more in demand for non-educational employment than any other group in the educational institutions in the United States.

If engineering education is to meet this challenge it must find a way to make engineering schools a more attractive environment for top-flight engineers and thus for top-flight teaching of future engineers.

The teaching loads in engineering schools are very high, with the result that their staffs have too little opportunity for the creative work that leads to further professional development both as teachers and engineers.

The engineering profession or society can no longer be adequately served by a professional engineering education that is predominantly undergraduate. While qualified recipients of the bachelor's degree in engineering frequently go on for graduate study in other fields such as the physical sciences and management, the amount of advanced study in engineering still seems small compared with the advanced study required by the professions of law and medicine. The number of advanced degrees in the United States in engineering, both master's and doctor's, in 1953–54 totalled about 4,800, while the totals of M.D.'s and LL.B.'s were 6,757 and 9,898, respectively.

Many educators are also advocating changes in undergraduate engineering courses, and engineering education seems to show signs of the bold experimentation and innovation that marked it in its early days when it was struggling to throw off the unsympathetic sanctions of classical education. There is a spreading conviction that the engineering curriculum must include a larger content of basic science, less of its traditional compartmentalization, more emphasis on such fundamental functional aspects o engineering as materials, thermodynamics, fluid flow and energy conversion. It bodes well for the future quality of technology that some of the new ideas are originating in the engineering schools. A superb opportunity exists to provide a new type of libera education polarized about science, unified by professional requirements, and relevant to the needs o our technological society. In the American institutes and schools of technology there is a vision of a new kind of university, a modern university built around science and social technology rather than classica studies, but embracing the arts, the social sciences and the humanities as essential and equal partners in its corporate aims and culture.

The goal should not be set as an academic numbers race with the Russians. The Russian educationa system serves the State, the American the individual The Russians are highly specialized in their scientific and engineering education and the United States is developing towards more fundamental generalized education, especially at the undergraduate-level.

One of the great difficulties is the surprising amount of fear of science and of a misreading of what science really is. Some of this adverse reaction arises from anti-intellectualism, from the disdain and distrust toward the learned man and the realm of reason. This drawing away from science is related to an attitude of antagonism and fear with respect to scientists. There is the common attitude that because a man is a scientist, he is disqualified for public and private administrative responsibility even though he may have all the qualifications.

This attitude reflects something wrong in the relationship of the scientist to society and in society's current estimate of the scientist. The scientist and engineer are themselves partly to blame for the manner in which their function in public affairs has been derogated. They have tended too much to professional parochialism.

The humanist, too, has a responsibility for this hurtful condition. There is still too much of the separatist spirit among the lower reaches of the humanists, too much facile criticism of science as materialistic, too much envy of the scientist for his intellectual achievements, too much protesting that only in the liberal arts can the true gospel of man be found.

It is the great humanistic responsibility of colleges and universities to stress the kinship, indeed the unity, of all knowledge, and to ease the vested interests and snobberies which sometimes appear among learned men. Objectivity, for example, is not the exclusive monopoly of science, nor humanism the tight monopoly of the liberal arts.

If science is to continue to prosper it must combat the notions that science and engineering are incompatible with the disciplines of the great humanities, and that they are narrowly materialistic and destructive of human values. Scientists have an obligation to make this true character of science better understood by the balanced and tolerant presentation of science as one of the powerful means by which man can increase his knowledge and understanding, and still remain humble and ennobled before the wonder and the majesty of what he does not understand.

As Dr. Caryl Haskins, president of the Carnegie Institution of Washington, recently remarked, it seems that the United States and Great Britain have problems in common with regard to the training of scientists and engineers and to the supply of the man-power of the right calibre. Dr. Killian's opinions as expressed in his address at the American Association proves this. All men of science and those concerned with scientific man-power problems would do well to read this address with the object of producing not only more, but also better educated, scientists and engineers in the future.

PRINCIPLES OF THE DYNAMO

Electromagnetic Principles of the Dynamo

By Prof. E. B. Moullin. (Oxford Engineering Science Series.) Pp. xi+367. (Oxford: Clarendon Press; London: Oxford University Press, 1955.) 50*s.* net.

It happens not altogether infrequently that a book which has been projected and upon which a substantial amount of work may have been done fails for one reason or another to achieve completion and publication. Most of those who, twenty-three years ago, read in the preface to Prof. E. B. Moullin's book, "Principles of Electromagnetism", that he hoped to publish shortly a book entitled the "Principles of the Direct Current Dynamo", must long ago have assumed that the volume would never now appear. On the contrary, this book, under the slightly altered title of the "Electromagnetic Principles of the Dynamo", has now taken its place in the literature of electrical machines.

Prof. Moullin explains in the preface that the manuscript, almost complete, lay aside from 1933 until 1950 and was then on the point of being discarded. At that time, Mr. G. E. Middleton, who had for many years been engaged on the design of electrical machines, joined the staff of the University of Cambridge, and he was invited to read the manuscript and express an opinion as to whether it would still be worth while to complete the book. Happily, Mr. Middleton recommended the completion of the task, and the author records his appreciation of the invaluable help rendered by him in the completion and revision of the manuscript.

The book conforms closely to the terms of its title and deals almost exclusively with the electromagnetic principles of direct-current machines. After an initial chapter on basic principles come five chapters dealing individually with the estimation of the ampere turns on the poles, the magnetic effects of the armature current, characteristic curves, efficiency and energy losses and commutation. These are followed by two chapters, one of which deals with a group of special machines, and the other, the last chapter, is entitled "Supplementary Matter". This treats in considerable detail certain topics which have been dealt with less fully earlier in the book and with a number of problems which link alternating-current with direct-current machines.

Perhaps the essential quality of this book can best be described by saying that, in it, the author has asked himself and has answered to his own satisfaction most of the searching and often awkward questions which an acute and critical mind would ask when presented with the conventional treatments of the theory of electromagnetic machines. Many of the paradoxes and conundrums which tantalized electrical engineers of an earlier generation receive serious study and elucidation. The induction of the electromotive force in the homopolar machine, the magnetic force on conductors embedded in slots and the e.m.f. in such conductors are examples of these problems. The treatments which are given of such topics as commutation and of the load characteristics of machines are exceptionally thorough and penetrating. There is a particularly interesting analysis of the Rosenberg dynamo, a machine which has nowadays a greatly increased interest as it is, in principle, the prototype of an important class of control machine.

At the end of the book is a collection of examples, eighty in number, taken for the most part from Cambridge examination papers, which illustrate the topics discussed in the text, each example being accompanied by an outline of its solution.

Mathematical analysis is used in varying degree in relation to nearly all the subjects with which the book deals, but no advanced methods are involved. The standard required is well within the competence of a second- or third-year university student. The real interest lies, however, in the critical questioning of the assumptions underlying many accepted pieces of theory and in their justification often by more than one method. This searching examination of the physics of machine problems, with the consequent quantitative assessment of the validity of assumptions, not only illuminates the problems themselves but also illustrates that spirit of inquiry which is an essential characteristic of the scientific mind.

This is a stimulating book which will interest and satisfy the teacher concerned with the subject of electromagnetic machines, and it will do the like for the student whose intellectual curiosity and insight have crossed the 'pons asinorum' of his subject. While it is clearly for the student that this book has been written, it is not too much to say that the experienced designer of electrical machines may find in its pages a new approach to some fundamental matter which may elucidate an intractable practical problem.

J. Greig

OPTICS OF CHARGED PARTICLES

Handbuch der Physik

Herausgegeben von S. Flügge. Band 33: Korpuskularoptik. Pp. vi+702. (Berlin: Springer-Verlag, 1956.) 122.50 D. marks.

The first volumes of the new "Handbuch der Physik" are out and give every promise of its being a worthy successor to the original edition of Geiger and Scheel, which appeared between 1926 and 1930. The intervening quarter of a century has seen some notable advances in international co-operation as well as great progress in physics itself, and both developments are reflected in the new edition. The contributors are drawn from many countries, and the articles may be in English, French or German. The progress of physics is reflected in the complete recasting of the treatment and its extension to fifty-four volumes. The change is exemplified in the subject-matter of Vol. 33, "Korpuskularoptik", one of the first of the new series to appear. Vol. 22 of the old series, the second edition of 1933, included mention of beta-ray and mass spectrometers and of electron diffraction; but there was little on sources of electrons and ions, and nothing on their optics. We now have a volume of more than seven hundred pages dealing with these subjects and with the electron microscope. The concern with instrumentation is new to the "Handbuch". The emphasis previously was very much on the fundamentals of physics; although technical physics in the wider sense was given some space, it has now been excluded in order to keep the number of volumes within reasonable limits.

The individual articles in Vol. 33 vary considerably in length and treatment. The first, on electron and ion sources, by D. Kamke, is perhaps too much a collection of types of ion guns (in eighty-five pages), and, even so, sources for accelerators are left to Vol. 44, where they will be treated in conjunction with injector systems. Electron guns are given only thirty-three pages, and a number of important aspects are comparatively neglected or omitted, such as the work of Haine and Einstein on medium-high-voltage guns and the more recent work of Klemperer on waist formation in electron beams. In general, very few pieces of work later than 1953 are cited. The section on electron and ion optics by W. Glaser, on the other hand, gives a balanced and thorough treatment of its subject. It is essentially an abbreviated version, in 270 pp. instead of 700 pp., of his monumental "Grundlagen der Elektronenoptik". Every topic of any importance is handled with rigour and economy, including deflecting fields and systems with curved axes. A supplementary bibliography includes references well into 1955.

Similarly, S. Leisegang's treatment of the electron microscope is a *zusammenfassende Bericht* in the best German manner. It runs to 150 pages with 137 figures and is almost a "Handbuch" in itself. In addition to the design and performance of the instrument, fundamental problems of image formation are dealt with, such as phase effects and energy losses in the specimen. The bibliography is up to date.

The final two articles, on mass spectrometers by H. Ewald and on beta-ray spectrometers by T. R. Gerholm, have much in common in mode of presentation. Each describes, in sixty-odd pages, the various types of instrument which have been devised for the respective methods of analysis: principles, practical details of construction, and efficiency of operation in terms of gathering aperture and resolving power. The treatment of beta-ray spectrometers is rather more critical, perhaps, in its comparison of different types. It ends with a conversion table, to six figures, from electron momentum (in gauss-cm.) to equivalent energy from just below 1 keV. up to nearly 30 MeV. The bibliography in each article runs into 1955. It is perhaps due to the geographical position of the author (Sweden) that, in addition to being the only one in this volume to write in English, he is also alone in making any appreciable reference to Russian work.

On the other hand, Gerholm's article is by no means the only one in which misprints occur with a greater frequency than is to be expected in a work of this kind, and in the German even more than in the English text. It is perhaps a reflexion of haste in publication, in an endeavour to keep to the announced intention of issuing the whole work within three years. Layout, printing and illustration are up t the standard of the earlier series, but the bindin may not stand up so well to the hard use which th "Handbuch" must expect. One other point need mention: the absence, not only from this volum but also from the list of contributors to others, o many of the leading exponents of the respectiv subjects. Looking back into Vol. 22 of Geiger an Scheel, one finds that most of the articles were b physicists who had been major contributors to thei subject: Bothe, Frisch, Gerlach, Hahn, Meitner Paneth, Ramsauer, Stern. Furthermore, it is no a question of 'hind-sight', as most were already o established international reputation and almost al held a chair at a German university. It is probabl another sign of the growth of physics, in speed an complexity of research as well as in its technica importance, that its leading men are now too bus to write reviews of their subject. In the present volume only one author bears the title of professor and he is now in an industrial laboratory in th United States.

V. E. Cosslett

RESEARCH ON BREWING

European Brewery Convention

Proceedings of the Congress, Baden-Baden, 1955. Pp. xi+358. (Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd., 1955.) 55s.

THE idea of science infiltrating into brewing still frequently produces a reaction from the layman on the grounds that, first, beer has been brewed for more than six thousand years, so there can be little still to learn; second, the less the scientist has to do with it the better because it used to be better than it is (in fact, it is even hinted that nowadays "beer is made from chemicals"); third (triumphantly), brewing is an art and not a science. The first two points are born of ignorance of the real position, and the truth of the third depends on the sense of the word 'art': in so far as it refers to experience and skill in 'know how' it may be correct. Convincing arguments could be presented to explain why research in brewing is necessary, but perhaps it is adequate here to say that more research is being done in this field than ever before.

In Britain there is the Brewing Industry Research Foundation, financed entirely by the brewing trade, and organizations of a similar, albeit less comprehensive and fundamental, character exist on the Continent of Europe and in North America. In Europe there was formed after the Second World War a Brewery Convention which embraces those countries with organizations competent to be members. Congresses are held biennially at different centres, and scientific and technical papers on brewing and malting are presented. The attendance has risen to several hundreds of brewers and brewing scientists, and so far the temptation has been resisted of splitting the meetings into two sections, one for the brewers and the other for the scientists. Should that happen, one of the chief objects of the founders will have failed.

The present volume contains the papers and discussions presented at the 1955 congress at Baden-Baden. A glance at the papers shows the high standard of most of the three dozen papers, including the reports of the Convention's two standing committees, on barley and analysis. The papers are grouped under headings covering raw materials: that is, barley and malt and hops; carbohydrates, proteins and yeasts (surely wide enough); and 'miscellaneous', covering topics from the influence of alcohols and esters on beer foam to the survival of pathogenic bacteria in beer.

Some of the papers on hops show the recent progress in hop resin chemistry, which has been quite significant. The eventual practical result will be the more economical use of hops by the brewer. Investigations on barley and malt range from dormancy to cytolytic activity during malting. An important activity of the barley committee is the arrangement of simultaneous trials in many countries on new varieties of brewing barley. A topic touched upon, and which may well attract more future attention, is that of the barley gums and polysaccharides other than starch of barley and malt.

Two other fields of perennial interest have papers devoted to them in this volume—yeasts and barley proteins. The mechanism of yeast flocculation in fermentation is still imperfectly understood, and the proteins in beer must always rank high in research because they are associated with the curse of haze and the blessing of 'head'.

The Convention has in preparation a six-language dictionary of brewing and malting terms.

H. J. BUNKER

A DICTIONARY FOR THE NEW WORLD

Webster's New World Dictionary

Pp. xiv+1702. (London: Macmillan and Co., Ltd., 1956.) 70*s*. net.

THIS "New World Dictionary" contains more than 142,000 vocabulary entries. It is an up-to-date record of words and phrases, giving full etymologies and a discriminative choice of synonyms. The entire work comprises a single alphabetical listing of words and their meanings, abbreviations, and personal, place and Christian names, etc. This has the distinct advantage of rendering it almost impossible to miss an insertion if it is there at all.

Both British and American forms of spelling are given, either in their alphabetical sequence or with cross-references. For example, there are about forty main entries with the prefix "sulf-", and one entry "sulph-", followed by a cross-reference to the others.

The insertion of the names of distinguished men and women in a general dictionary of this sort is open to question. For example, Sir Alexander Fleming is described as "one of the discoverers of penicillin"; there is no indication who the others were, and Sir Howard Florey is not included. Lord Rutherford is described as a "British physicist, born in New Zealand; received the Nobel prize in chemistry, 1908"—not a very informative description of the great atomic physicist for a general reader. James Watt is described as a "Scottish inventor", but what he invented or discovered is not given. Yet, in other cases the compilers show considerable ingenuity in their brief descriptions; for example, Charles Darwin is described as the "English naturalist, originated theory of evolution by natural selection".

It is difficult to conceive of the qualifications needed by any living or dead person to justify his inclusion in such a compilation as this. Browsing at random, one comes across the names of Bohr, the two Braggs (William and Lawrence), Conant, Julian Huxley and Urey. Appleton appears not under his own name but under "Appleton layer". Conversely, thinking at random, one looks for Bronk, Chadwick, Dale, Hale, Meitner and Spencer Jones; but these are not there. Again, among the abbreviations, UNESCO is explained, but not WHO. There are only three insertions under the abbreviated form of "Fellows" of learned societies, namely, F.R.S. (Fellow of the Royal Society—though the Society itself is not inserted), F.R.S.L. (Fellow of the Royal Society of Literature) and F.R.S.S. (Fellow of the Royal Statistical Society). In order to avoid the sins of omission and commission in a compendium such as this, it might have been wiser to omit proper names, abbreviations and very technical terms and to stick to general words and their meanings; for the resulting tendency is to become a not very comprehensive encyclopædia which might give only enough information to enable the reader to satisfy the question-master in a parlour or quiz game.

Again, where certain common names have connotations different in the New World from the Old, then the definitions should be more explicit. For example, "cowslip" is described as "1, the marsh marigold, a swamp plant with yellow flowers. 2, a wild plant of the primrose family with yellow flowers; English primrose". This description would have been more informative and less misleading if it had ended at the semicolon, and if '(Amer.)' had been inserted at the end of 1, and '(Brit.)' at the end of 2. "Bluebell" is described as "any of the various plants with blue-bell-shaped flowers, as the wild hyacinth, harebell, etc.". This vague approach will cause many local arguments. The "snowdrop", besides receiving the correct British identity, is also defined as the "common anemone"; whereas "hazel" is described as a group of trees or shrubs of the birch family. British botanists will lift their eyebrows at these loose and, in some cases, erroneous definitions. The term "Alsatian" from the canine point of view is described only as "a variety of police dog"; but this breed did not originate from Alsace, though the reason for the name is well known. Cross-reference to "German shepherd dog" should have been given. Among the examples of "black-birds" is "the common English thrush"; the "robin" is described as "1, a large North American thrush with a dull-red breast and belly. 2, a small European thrush with a yellowish-red breast". Generally speaking, this may be accepted by the ornithologist; but it is just terse enough to confuse a layman.

The examples given indicate the difficulties of compiling a dictionary which will satisfy both the British and the American English-speaking peoples. Perhaps the compilers have aimed at too many insertions at the expense of clarity and sometimes even accuracy. Indeed, it seems that the time has come when we must admit that British and Americans, though speaking the same language basically, have rather different vocabularies. This New World Dictionary will certainly satisfy the general inhabitants of the New World, for it is biased in that direction. Nevertheless, many of the technical terms which are common to both worlds are quite cleverly defined and are certainly up to date; so it might well be worth considering an Old World version of this New World Dictionary.

Handbuch der Physik

Herausgegeben von S. Flügge. Band 2: Mathematische Methoden, 2. Pp. vii+520. (Berlin: Springer-Verlag, 1955.) 88 D. marks.

This is a valuable compendium of methods of mathematical physics which, while in no way threatening the pre-eminence of "Courant–Hilbert" and "Jeffreys and Jeffreys", makes its own selection of material and thus contains some valuable techniques which are absent from those standard works. It is stronger, particularly, on algebraical and geometrical methods. A fairly substantial account of the theory of groups (including group representation), rings, fields, ideals and linear algebras, with indications of fields of their application, is given first. It is followed by an account of analytical geometry, differential geometry and field theory, Riemann geometry, tensors, spinors, and canonical transformations. Next follows the longest section—functional analysis, by Prof. I. N. Sneddon; this section is in English, whereas the rest of the book is in German. He begins with a synopsis of Banach space theory and then goes on to a rather full account of integral transforms, including the Laplace, Fourier, Mellin and Hankel transforms, and various finite transforms such as the Legendre transform and other transforms arising from equations of Sturm–Liouville type. This section concludes with an account of operators in Hilbert space and Schwartz's theory of distributions.

The following, and second longest, section of the book is a fairly full account of numerical and graphical methods, which though on conventional lines contains many useful tips about practical procedure. Half this section is devoted to initial-value, boundary-value and eigen-value problems for ordinary and partial differential equations and to integral equations and functional equations. The book concludes with a rather brief account of modern computing machines of both the analogue and digital types. There are subject indexes, both in English and in German.

Like "Courant–Hilbert", the book will perform its most useful service by introducing to applied mathematicians a number of techniques which they are apt sometimes to regard (erroneously) as proper only to investigations in pure mathematics. A copy could usefully be purchased for any mathematics or physics library.

M. J. Lighthill

Thermodynamics and Statistical Mechanics

By Arnold Sommerfeld. (Lectures on Theoretical Physics, Vol. 5.) Translated by J. Kestin. Edited by F. Bopp and J. Meixner. Pp. xviii+401. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1956.) 7 dollars.

Sommerfeld died before completing this present volume of his theories on theoretical physics, but he had done a good deal of the work and the plan of the rest was clear enough for Profs. Bopp and Meixner to complete it, following as closely as possible the author's intention.

The book, which is now available in translation, shows no sign of these difficulties, and the treatment has preserved throughout Sommerfeld's characteristic clarity of approach and his emphasis on physical principles. He follows Boltzmann rather than Gibbs, even to the point of having to resort to the Darwin–Fowler contour integration method in the derivation of Fermi–Dirac and Bose–Einstein statistics in order to cope with the combinatorial difficulties. To the reviewer, who was introduced in Sommerfeld's lectures to the beauty and simplicity of the method of the grand canonical ensemble, this is a source for regret. It is clear from the author's preface as well as from the note by the editors that Sommerfeld himself was not satisfied with this section and might have intended to change it if he had had the opportunity to do so.

The treatment starts with thermodynamics as a logically independent subject and only later reaches statistical mechanics by way of the elementary kinetic theory of gases, an order which is not only the historical but also the simplest one logically if perhaps not deductively.

Chapter 4, which deals with the general principles of statistical mechanics, is perhaps the least satisfactory for the reasons already stated.

Chapter 5 gives an outline of an exact kinetic theory of gases and covers, in particular, transport phenomena and deviations from statistical equilibrium. This chapter, which is almost entirely due to the editors following what seemed to be Sommerfeld's intentions, is a useful addition in bringing out a very practical approach to many problems not usually covered in such books.

The book is a welcome addition to the text-books on this subject. Like the others in the series, it displays Sommerfeld's attitude of putting practical problems and their solution above abstract principles, an attitude by its nature closer to Boltzmann than to that of Gibbs.

The Chemical Constitution of Natural Fats

By Prof. T. P. Hilditch. Third edition, revised and enlarged. Pp. xix+664. (London: Chapman and Hall, Ltd., 1956.) 95s. net.

Since the second edition of this book in 1947, there has been a broadening of interest in the natural fats, which, through their number and variety, provide almost endless opportunity for systematic study. This has occurred, first, because shortages due to war and later economic factors have stimulated research for alternative fats for food and other purposes; at the same time, the development of new and more delicate methods has brought rewarding results in a field in which their introduction had become essential if further important advances in knowledge were to be made. Prof. T. P. Hilditch has thus been faced with an arduous task in incorporating the mass of new material available in the third edition of this book, and he has overcome the difficulties with much success.

The new edition naturally contains extensive additional data on the fatty-acid composition of many fats. More important, however, are the three rewritten chapters which discuss recent material advance in knowledge concerning the component glycerides, the nature of which plays a part in determining the industrial uses to which fats are put. Two other largely rewritten chapters also call for comment. The first is that which is concerned with the chemical constitution and synthesis of fatty acids, particularly of the naturally occurring unsaturated acids, and of some acids which occur rarely and in small amount. Many uncertainties are now cleared up, and some of the findings may prove of considerable importance in the biochemical understanding of fats. The second is important because in it are presented the methods of research on fats, with particular emphasis on such newer approaches as low-temperature crystallization from solvents and spectrophotometry, which are yielding valuable results.

This book, which includes findings published as recently as the end of 1954, thus remains a comprehensive reference book of great value in the field of natural fats and reflects throughout the experienced judgment of its author, who has carried out so much pioneering work on this subject for so many years.

Comprehensive Inorganic Chemistry

Vol. 4. Edited by Prof. M. Cannon Sneed and Prof. Robert C. Brasted. Zinc, Cadmium, and Mercury; by Howard M. Cyr and the Editors. Scandium, Yttrium, and the Lanthanide Series; by Thomas D. O'Brien and the Editors. Pp. xii+193. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1955.) 37*s.* 6*d.* net.

In judging a book like this, one naturally takes a few test samples, preferably on familiar topics; so I started by looking up the separation of the rare earths. I found that solvent extraction was dismissed as being no better than fractional crystallization; the authors have evidently overlooked the not inconsiderable literature on the use of tributyl phosphate. Ion exchange was somewhat better assessed; but the account was marred by a quite inadequate description of ion exchangers in general, going right back to peat, greensand and clay, which no sensible person would attempt to use for the separation of the rare earths. Moreover, the facts about the ion exchange methods actually used for the rare earths seemed scrappily chosen. A minor point was the use, without explanation, of the name "Manhattan Project". Does everyone nowadays know the name?

Next I tried looking up the calomel electrode, on which I found two sentences, giving its potential and its reproducibility, but no word at all of what it is or how it works. There were indeed similar inadequacies at every sampling point, although some attempt seems to have been made to repair the deficiencies of earlier volumes by means of a liberal sprinkling of thermodynamic and crystallographic data.

The root of the trouble probably lies in the basic conception of the series, with its uneasy combination of encyclopædic treatment with efforts to inculcate basic principles. The two can be integrated, as Sidgwick has shown. But inorganic chemistry is now so vast and complex that we shall probably be better served in future by books falling definitely into one category or the other.

Physical Properties of Chemical Compounds

Compiled by R. R. Dreisbach. Edited by the Staff of *Industrial and Engineering Chemistry*. Pp. iv+536. (Washington, D.C.: American Chemical Society, 1955.) n.p.

This book tabulates, for 504 cyclic organic compounds, properties such as boiling point, density, viscosity, latent heat and a number of derived values (for example, constants for the Antoine equation). Some properties have been checked or derived by the use of well-known equations or of others devised by the compiler.

The compounds may be put into two classes; the first comprises hydrocarbons (328) and sulphur compounds (51). For these, the primary data are drawn from the work of the American Petroleum Institute Research Projects. It is known that properties have been determined by these for a large number of highly purified compounds; but, to the outsider, it would appear that, for some items recorded by Project 44, for example, tritriacontyl*cyclo*pentane, values have been derived by mathematical relationships such as were devised by Smittenberg for density and refractive index in some homologous series of hydrocarbons. If this is so, it is perhaps questionable how far one is justified in applying further equations to values so obtained.

The other class is a miscellaneous group: phenols (52), halogenated benzenes (27), amines, etc., for which the basic data have been taken from the general literature or have been specially determined in the Dow laboratories.

Among minor comments, the title of phenol 25 has been mistyped, the tertiary amyl group is consistently formulated as $—CH_2{\cdot}C(CH_3)_3$, and the calculated surface tension of *n*-tetratriacontylbenzene is quite out of step with that of its several neighbours. There is, however, one serious blemish; phenols 37 and 51 are the same compound recorded under different names and, except for molecular weight and PV/RT, every figure differs, that of the boiling point by 11°. The seriousness lies in the fact that the data for forty-six other phenols have been taken from the same source as those for 37, so that, short of drawing invidious distinctions, at least a shadow of doubt falls on about a hundred items.

B. A. Ellis

Minerals in World Industry

By Prof. Walter H. Voskuil. Pp. vii+324. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 43*s.*

This is an authoritative study of the part played by commercially important deposits of mineral substances in peace-time economy, and also in international politics. It has taken two World Wars to bring home to both politicians and the public the prime importance to great nations that lies in the possession or control of deposits of what have often been termed 'strategic' minerals; and, conversely, the consequences that can ensue, particularly under conditions of modern warfare, when such supplies are cut off. There are, too, other aspects of the question. It should, for example, be a matter of much greater concern than it seems to be in Britain that, having extensive coal reserves, the nation seemingly prefers to import coal from abroad rather than make full use of them. Certain aspects of mineral economy have indeed received much publicity lately in Britain, notably the search for sources of the minerals used in the development of atomic energy, and the question of political control in the major oilfields.

Apart from coal, oil and the ores of such well-known metals as iron, copper and aluminium, there are many other minerals, metallic and non-metallic, which are essential for the highly developed chemical, engineering and metallurgical industries, and also for agriculture and food production. There are, too, a number of little-known metals, such as titanium, zirconium, germanium and rhenium, which already play an important part in industry, or are likely to do so in the near future. The author discusses the mineral resources of the world, both geographically and statistically, and the economic, social and political consequences that arise from their uneven distribution.

This is a thoughtful book, which should appeal to all whose interests extend beyond the borders of pure science.

WILLIAM BUCKLAND (1784–1856)

By J. M. EDMONDS

Department of Geology and Mineralogy, University of Oxford

AUGUST 14 of this year marks the centenary of the death of Prof. William Buckland, D.D., F.R.S., sometime reader in mineralogy and in geology in the University of Oxford and also Dean of Westminster Abbey. As the sponsor of the 'glacial theory' in Britain, he opened up a completely new field to physiographical investigation; he was among the first to recognize the comparatively late geological date of the great upward movement of the Alps; he described the fossil reptile, *Megalosaurus*, from Stonesfield, Oxon, and he illuminated a large variety of geological and palæontological problems by his researches.

It was after taking his B.A. degree at Oxford in 1804 that Buckland began to attend the lectures of Prof. John Kidd on mineralogy and chemistry, and those of Sir Christopher Pegge on anatomy, while, during the vacations, he searched out the field-evidence which was then being gradually brought together in order to establish the geological succession of strata, scarcely known at that time even in outline. In 1813, Buckland followed Kidd as reader in mineralogy in Oxford, and the success of his courses was such that, on the intervention of the Prince Regent, a readership in geology was endowed in 1818, and to this Buckland was also elected.

When Buckland delivered his inaugural lecture, "Vindiciæ Geologicæ", in 1819[1], the chief challenge to him as a theologian was to reconcile the evidence revealed by the young science with the accepted teachings of the Scriptures. He set out the facts as he saw them, which supported his belief in the 'Mosaic records', but introduced the hypothesis that there was an undefined period of time before the last great change that affected the surface of the Earth and before the creation of its present animal and vegetable inhabitants, a period during which a long series of operations and revolutions were going on "wholly unconnected with the history of the human race". Four years later, he adopted the same point of view in his first major work, "Reliquiæ Diluvianæ"[2], which was essentially a record of his own exploration and excavation of caves with a description of the animal remains found in them. To this was added an account of the 'diluvial' deposits (surface gravels, sands and loams). These he linked in date to the cave deposits by means of the fossil content of elephant, rhinoceros, hippopotamus, bear, tiger and hyæna, which are no longer present in Britain but which were shown by him to have inhabited the country with more familiar animals in 'antediluvian' times.

There is no continuous record of the modifications which came to Buckland in his interpretation of this problem, which so limited the horizon of contemporary thought. There seems to have been no fundamental change in his views in regard to the origin of the surface deposits by 1836 when he published "Geology and Mineralogy considered with Reference to Natural Theology"[3], although he now ascribed them to causes distinct from "the comparatively tranquil inundation described in the Inspired Narrative".

The accounts of grooving and scratching of surfaces of solid rock by the movement of boulders (believed to have been carried along by water) had long been known to Buckland, and he had himself observed that these markings showed some alignment in particular localities. In 1838, he was shown polished, striated and furrowed surfaces and transported granite boulders by Louis Agassiz in Switzerland, where they were attributed by the latter to the agency of ancient glaciers. When he had confirmed the explanation by means of an independent examination of existing glaciers in the Alps, Buckland began to relate it to similar phenomena in Scotland and northern England. At the Glasgow meeting of the British Association in 1840, Agassiz described the action of glaciers and the deposits associated with them, and then he accompanied Buckland to examine the evidence for former glaciation in Scotland. Soon they returned to London to present their findings to the Geological Society, of which Buckland was then president. Their exposition, together with a paper by Lyell (whom Buckland converted after the Glasgow meeting), was the introduction of a new theory regarding the origin of much of the surface deposits covering Britain, and Buckland went so far as to assert[4]: "The subject appears to me the most important that has been put forth since the propounding of the Huttonian Theory: and the surface of the whole Globe must be examined afresh with the view of ascertaining how far the effect of Glaciers and Ice-bergs and of Floods produced by melting ice and snow can be found and identified with the actual effects of ice and snow in our present polar and Alpine regions".

It is probable that Buckland's most important contribution to geology was his ability to present palæontology and the past history of the Earth in such vivid terms. In the "Bridgewater Treatise" and in his lectures, fossils were no longer treated as markings on stones or even as the dead remains of unknown animals; they became the key to the understanding of the sequence of past inhabitants of the Earth. An impression of a footprint on a slab of rock could disclose the size, attitude and even the shape of an animal; a tooth show how a creature lived; coprolites reveal the shape of the intestines and the undigested fragments of the food.

At first in Oxford and later among wider audiences, his lectures aroused remarkable enthusiasm:

> "In Ashmole's ample dome, with look sedate,
> 'Midst heads of mammoths, heads of Houses sate;
> And tutors, close with undergraduates jammed,
> Released from cramming, waiting to be crammed."

The registers show that in 1819, immediately after his inaugural lecture, the Vice-Chancellor and the Junior Proctor paid the statutory fee for the course on the elements of geology. Among the young men were Charles Lyell and John Henry Newman (later Cardinal). In 1823, Buckland wrote to a correspondent: "I have this day been occupied in lecturing to an overflowing class amongst whom I reckon the Bishop of Oxford & 4 other Heads of

Colleges, and 3 Canons of Chch [Christ Church] on the newly discovered Caves. . . .".

In 1845, Buckland was appointed Dean of Westminster, and although he still travelled to Oxford to give his lectures, the popularity of the subject had declined in the University and the numbers attending his courses had fallen to an average of ten persons. The efforts of the scientific professors had for some time been bent towards the inclusion of the natural sciences among the subjects in which undergraduates might be examined for a degree, and Buckland had earlier been prominent in support. The recognition was won in 1850, but in its final stages it came without Buckland's backing, for in 1847 he refused to add his signature to a memorial, prepared by some of his scientific colleagues, asking for a building to house the natural science teaching collections and to contain lecture rooms for the professors. His reasons for his refusal to sign were rather an expression of despair than of lack of regard: "Some years ago I was sanguine, as you are now, as to the possibility of Natural History making some progress in Oxford, but I have long come to the conclusion that it is utterly hopeless".

Whatever were his disappointments in his own University, Buckland attained a high position in the scientific world outside. The Royal Society, the British Association, the Geological Society all provided him with a forum, and he was prominent in support of agricultural, civil engineering and archæological societies. He lectured, entertained and travelled widely, and his friendship with Sir Robert Peel gave him access to a wide and influential circle. With Prof. Adam Sedgwick and Charles Lyell, he prepared the report which resulted in the formation of the Geological Survey of Great Britain, and he later helped towards the establishment of the School of Mines and the Mining Records Office.

As Dean of Westminster, Buckland found his abilities diverted into an entirely different channel of service in the maintenance of the functions and the fabric of a great religious house. He made many improvements in the precincts of both Abbey and School just before the cholera epidemic of 1849, and on the day of thanksgiving for its ending he preached a sermon which was a remarkable plea for sanitary reform in London. He contrasted the cholera-ridden city with the towns of Nottingham and Newcastle upon Tyne, to which water had just been brought; and with Birmingham, "standing on a salubrious rock of clean and filtering porous sandstone". He included a demand for "one grand comprehensive system for a general supply of fresh water near to every house", and "a simultaneous removal of all impurities at the moment of their production, by means of a combined and systematic arrangement of sewage".

THE BIOLOGY OF OLD AGE*

By Dr. ALEX COMFORT

Department of Zoology, University College, London

CONTROL over the rate of human ageing and the transmutation of elements are long-standing and closely associated human ambitions. They have at various times been considered by scientists as a leisure occupation, pursued by magicians and charlatans, or regarded as fundamentally impossible. The second has now been achieved by physicists, though in circumstances far from its traditional context; the first may well be the next major problem to be attacked by medical biology.

Much of the work necessary to increase our knowledge and control of age processes is descriptive and clinical, but the whole problem poses many extremely important questions in general biology, and involves the collection of data in very diverse fields, both descriptive and experimental. A detailed bibliography of the work summarized in this article has been published[1].

The general theories devised in the past were commonly based on the assumption that senescence must involve a single 'fundamental' cellular or chemical process common to all multicellular organisms, and contrasting with the unfortunately named 'potential immortality' of protozoa. None of these assumptions can now remain unquestioned—it seems very probable that there are many multicellular animals which are capable of indefinite cell replacement without loss of vitality, while in some unicellular organisms such as suctorians, where mother and daughter cells are clearly identifiable at fission, the age status of the fission products is not identical, and individuals have a fixed life-span which can be modified experimentally[2]. It is probably wise to assume that, in those animals where vigour does decline with age, the responsible processes are multiple, and to treat senescence as the sum of all those factors—from mechanical wear of teeth or chitin to more complex endogenous changes—which progressively impair homœostasis. A general definition of this kind, as well as being convenient, is theoretically justified by the place which senescence seems to occupy in evolution[3,4]. In a population subject to the high mortality which is common to many animals in the wild, the evolutionary relevance of individuals, and hence the selection-pressure towards vigour and homœostasis, probably decline very rapidly with increasing age: the common feature of all ageing processes in animals may be that they represent a 'running out of programme', and an escape from the selection pressures which maintain fitness at the ages when contribution to the next generation is greatest. One manifestation of this may be the failure to eliminate late-acting lethal genes, for where individuals very rarely reach even mid-adult life unless protected, the postponement of an adverse effect is as effective an adaptation as its removal. If this is so, we might expect the processes which limit the lives of different animals to be diverse. At the same time, in view of the general similarity of animal cells throughout phylogeny, the likelihood that some deteriorative processes at the cellular level are shared by all animals whose powers of regeneration are incomplete is sufficient to justify wide comparative study.

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution, London, on June 1.

Animal Life Tables

By far the best measure of senescence in a population of organisms is their liability to die at different ages. If we had a full account of the relation between growth, age and mortality in a sufficient range of representative animals, the truth of many existing general theories of senescence could probably be tested by inspection. Those actuarial studies which we have suggest an inverse relationship in phylogeny between degree of cell-replacement and liability to senile change. Thus death from old age in rotifers and nematodes, where the cell number is fixed, is sudden and unanimous, with obvious cellular change, whereas in sea anemones the cell turnover is probably continual, and they appear to remain indefinitely vigorous.

It is particularly important now to obtain accurate actuarial figures for the main types of vertebrates. Although typical senescence, with a sequence of changes similar to that in man, almost certainly occurs in all mammals and birds, the longevity of birds is strikingly greater than that of mammals of comparable size and activity (29 years in a chaffinch, compared with 3–4 in a mouse), and there are large differences between closely related species. It is also by no means certain that all poikilothermal vertebrates do in fact undergo any marked change in mortality with age, beyond that resulting from the accumulation of evident injuries. It has been suggested that the particular type of ageing found in mammals is in some way connected either with homoiothermy, or with the evolution of a fixed specific size. Bidder[5], from work on the continued growth of plaice at high ages, put forward the theory that senescence in its mammalian form is the direct result of growth-inhibitory mechanisms evolved during the transition to life on land to limit adult size, and that it does not occur in fish or reptiles which grow continuously, or remain capable of doing so.

In view of hypotheses like these, one of the main preoccupations of comparative research on ageing is the collection of animal, and particularly vertebrate, life tables, based on animals living under conditions of captivity sufficiently good for a fair proportion of them to reach old age. So far as can be ascertained, no life table based on a captive population has ever been published for any fish, reptile or amphibian. The longevity of many small species (14 years in frogs and 25–30 in newts) makes it almost impossible to seek experimental data directly. One incomplete life table exists for domestic poultry[6], and this is constructed on an assumed equation. Apart from these, we have satisfactory actuarial data only for man, laboratory rats and mice, and a few other rodents (*Microtus*[7,8], *Mastomys*[9]), with partial figures for a few agriculturally important animals (for example, merino ewes[10]). No general view of mammalian age processes can yet be obtained, and in view of the time necessary to follow experimental populations, the deficiency can be remedied only by the unearthing of already existing data. The possible value of such information in comparing the life-spans of similar animals, in correlating patterns of growth and of age-mortality, and in the criticisms of general theories of ageing is still not sufficiently widely appreciated. Actuarial figures for all the main breeds of dog, for example, would be of great interest. Workers who normally keep large animal populations, or who have suitable records, could help greatly in this work by bearing these needs in mind. The same applies to accurate data on maximum life-spans: the quality of the information available was greatly improved by the work of Flower, but many, if not most, of the commonly quoted figures are still based on legend.

Studies on specially kept populations of small aquarium fish have demonstrated a pattern of senescence which, in the guppy (*Lebistes*), is very similar in its time-scale to that of laboratory rats (median $\simeq$ 500 days, limit $\simeq$ 1,200 days), and which occurs at a rather similar rate in both sexes, although the adult size of the males is fixed by growth cessation early in life, while the females may continue to grow at any age. This fish is particularly suitable for experimental work on poikilothermal growth and ageing, since it readily survives handling, and its growth can be precisely controlled by altering its food intake and living space. We are taking advantage of these properties in a number of experiments to study the effect of age and of various growth regimes on the force of mortality in a poikilotherm.

Cytology

There are a number of cytological problems, quite apart from descriptive pathology of senile changes, which should be susceptible to investigation. One of these, in view of the correlation which appears to exist between senescence and cessation of cell division, is the sequence of changes which limits the life of non-dividing cells. Some of these changes, like those in rotifers, occur visibly and should be accessible to microchemical and enzyme studies.

It is probably true that the life-span of all fixed postmitotic cells is limited in terms of molecule turnover. Spoilage of enzyme systems in such cells probably accounts for the senescence of animals the cell number of which, as in rotifers, is strictly determinate. A similar process in cells such as neurones might play a part in the senescence of vertebrates; but very little is known of the life-span and replaceability of any tissue cells *in situ*, and it is quite possible that in higher animals which senesce there is a change in the quality and responses of successive cell generations.

The question whether changes due to faulty copying are inherent in clones, and if so whether metazoan bodies are analogous to other clones in this respect, was asked long ago by Maupas, and cannot yet be answered with certainty, except to the extent that there are apparent instances among plants and protozoa of both stable and unstable clones. Recent work by Sonneborn and his school has shown that the degeneration of clones of *Paramecium* is probably due to uneven distribution of the chromosomes of a highly polyploid macronucleus between daughter cells. This process is presumably peculiar to ciliates; it might be that something similar occurs in somatic cells, or in some of them, through distribution of cytoplasmic structures, or through aneuploidy, but there is so far no evidence that this is a factor in metazoan ageing.

Another relevant question is the effect of cell division on the age-status of the fission products. The fact that suctorians have a demonstrable life-span has already been mentioned. It would be interesting to know whether in cases where one fission product receives a newly formed and the other a pre-existing organelle, this difference confers any difference of viability. The assumption that in any fission without differentiation the daughter product is a pair of cells equal in age status may require re-examination, both in acellular organisms and possibly, by photographic means, in tissue cultures. The construction of life tables for various mammalian somatic cells, by labelling techniques such as are now used *in situ* for red blood cells, is also probably not out of the question, and would be well worth the attempt.

Experimental Physiology and Genetics

In 1935 McCay[11] and his co-workers showed that rats which were kept in a juvenile condition by calorie restriction could be restarted in growth at ages up to and even a little beyond a thousand days, and that the period of retardation represented a true postponement of the senile increase in mortality, the life-span being increased by that amount. This is perhaps the most important piece of information so far; but although it is twenty years old, little more has been done to determine which components of development must be retarded in order to slow down ageing. Dietary restriction after puberty lengthens the life of rats, but only by a much smaller amount: intermittent fasting (one day in three) and restriction of diet (short of preventing growth)[13] have both been found to lengthen the life of rats; but in these cases the increase was less striking, and more closely related to the avoidance of surfeit diseases than to developmental slowing.

An incidental implication of McCay's work is that the optimal dietary intake for human growth in childhood might not be that which produces the longest total life-span. McCance and Widdowson[14] and Sinclair[15] have suggested that by pursuing rapid growth in childhood dietitians might be shortening the plateau which normally occurs in the human prepubertal growth curve, and possibly reducing the life-span, either by that amount or even by more. The age of puberty in Western countries is said to have shown a substantial advance over the past century. Maturity, judged both by the date of the menarche in girls[16] and the age of maximum stature in boys[17], has advanced in that time by as much as seven years. This may possibly represent a reversion to an older pattern which had been disturbed in the 1800's, and its cause is unknown, although diet, better economic and social conditions, and heterosis due to a reduced degree of inbreeding have all been invoked. Life statistics cannot be used to determine whether earlier development has altered the rate of ageing, since the gain in expectation of life from medical science is much larger than the loss which might be expected. Where rapid development is genetic in origin it is usually a character of vigour, and in human congenital precocious puberty, where menstruation may begin at the age of two or three years, the expectation of menstrual life is greater, and that of total life no less, than in normally timed individuals[18]. This might not be true of dietary acceleration: the optimal rate of human development is difficult to establish, but it seems that we may still need to establish it.

The only experimental procedures which can at present produce increases in mammalian life-spans equal to those due to dietary restriction are genetic. There is a correlation between human parent and child longevities, but it is only a quarter of that for stature[19]. The life-span of laboratory animals can be increased by eliminating specific heritable disease, but the tendency of inbred stocks is to reach a stable life-span shorter than that of random-bred animals[20,21]. This can be increased, and sometimes doubled[22], by hybridization, though probably not beyond the figure for fully heterozygous 'wild' individuals of the same species (direct comparison with wild-caught stock is greatly complicated by other factors). The mechanisms responsible for the vigour of hybrids may prove significant in studies of ageing: the differences between hybrid and inbred animals are in some ways similar to those between young and old, especially the low variance of many characters in hybrids and their greater resistance to outside disturbance[23,24]. Both old and inbred animals appear to have a diminished repertoire of responses to biological stresses. It should be instructive to analyse this similarity in specific cases.

Apart from these questions, there is a rapidly growing range of methods which can now be used to study ageing along the lines of classical experimental physiology. The improvement of grafting techniques and the knowledge of their limitations make it possible to create age chimeras, the use of these being to study the mutual interaction of host and graft of different ages, rather than in the first instance the endocrine effects of young grafts on ageing animals, as in the past. It is also possible through the use of storage techniques to re-implant tissue taken from infant animals in the same animals when they are old. The obstacles to larger experimental procedures of this kind are chiefly problems of tissue compatibility—the surgical techniques available already permit work such as the complete transplantation of heart–lung preparations in dogs, and their exchange between animals, carried out routinely by Demichov at the Vishnevsky Institute; the survival of these large-scale transplants is limited only by the homograft reaction. Ingenious ways of overcoming this in specific cases, such as the intra-embryonic injection of cell antigens recently described by workers at University College, London[25], might eventually make possible the creation of very extensive age chimeras. Organ culture, which has been relatively little pursued since the early work of Carrell, offers yet other possibilities in this direction.

Classical methods can also be applied to the endocrinology of ageing, with the powerful reinforcement of paper chromatography. Much previous work in this field may have been based on false assumptions, and it now seems decreasingly probable that mammalian age changes will prove controllable by hormones alone, even when more of them are available: the most promising in this field may prove to be those controlling protein anabolism. The endocrinology of timing mechanisms—in particular, those affecting puberty and the menopause—is of great importance, and is already under examination. The second of these is complicated by the lack of laboratory animals which follow the human pattern; the first offers some promise of finding a developmental timekeeper in the central nervous system, which might open very wide fields of investigation.

To those engaged in any of these studies, however, the main requirement of progress is a wide awareness among biologists in general of the nature and scope of the problems which age studies raise, since only through this will the additional information we need be forthcoming.

OBITUARIES

Dr. John Wishart

Dr. John Wishart, reader in statistics in the University of Cambridge, was born in Perth on November 28, 1898, and was educated at Perth Academy and the University of Edinburgh, where he was one of the many able mathematicians taught by Sir Edmund Whittaker. After leaving Edinburgh he spent two years teaching at Leeds, and then went in 1924 to the Galton Laboratory at University College, London, as research assistant to Prof. Karl Pearson. He stayed there three years, and after a brief period at the Imperial College of Science and Technology, joined the staff of the Rothamsted Experimental Station in the statistical department just at the beginning of its great period of expansion under Sir Ronald Fisher's inspiring leadership. He made his mark there, and left to become reader in statistics at Cambridge in 1931. During the Second World War he served as a captain in the Intelligence Corps during 1940–42 and was a temporary assistant secretary at the Admiralty during 1942–46. He was a Fellow of the Royal Statistical Society, of the Institute of Mathematical Statistics and of the American Statistical Association, a member of the International Institute of Statistics, and an associate editor of *Biometrika*.

To one who was associated with him from the earliest days and in all three places where his life-work was done, the tragedy of his early death at the age of fifty-seven is only too apparent. He was drowned in a bathing accident in Mexico on July 14, during a visit to Central America on behalf of the United Nations Food and Agriculture Organization, to organize a research centre for the teaching of statistics in agricultural research.

Wishart was the author of three books on field experimentation and many research papers on mathematical statistics in scientific journals. His scientific work was characterized by exceptional accuracy and attention to detail, with which he combined more than usual organizing ability. The first of these characteristics was shown in his earliest papers on the numerical computation of certain integrals; the second became manifest at Rothamsted, where he helped with the organization of field experimental programmes and for several years carried out most of the statistical analysis. His best-known paper, produced at Rothamsted, was concerned with what came to be known as the 'Wishart distribution'. This is the generalized product moment distribution in samples from a multivariate normal population. Another of his main theoretical interests was the development of explicit formulæ for the cumulants of 'k statistics' using Fisher's combinatorial methods. This subject formed an important part of the lectures which he gave at Cambridge, and he returned to it as late as 1952.

Wishart was at his best in the years 1931–39, when as a result of his teaching at Cambridge, the modern statistical outlook was adopted by a number of Cambridge mathematicians who took up statistics as a career. They spread the knowledge of statistics as a scientific subject and did much to set up a chain-reaction which still continues. Their training made them aware of the almost unlimited potentialities of statistical methods in many diverse fields, and there is still no sign of diminishing *tempo* in their application.

J. O. Irwin

Prof. E. A. Braude

By the sudden and untimely death on July 23 of Prof. E. A. Braude we have lost one of the most brilliant and most active of our younger organic chemists.

Ernest Braude was born in Germany in 1922, came to Britain as a boy of fifteen, and was naturalized at the age of twenty-four. His British education started in private schools and at Farnham Grammar School. He spent one year at Birkbeck College before going to the Imperial College of Science and Technology, where he spent virtually the rest of his academic life. He graduated with first-class honours in chemistry in 1942, receiving the Acland and Frank Hatton Prizes. He spent the next three years as research assistant to Sir Ian Heilbron, became an assistant lecturer in organic chemistry in 1946, lecturer in 1947 and reader in 1952. He succeeded to the chair of organic chemistry in 1955. In 1950 he received the Meldola Medal of the Royal Institute of Chemistry and the D.Sc. of the University of London.

Braude published his first original papers at the age of twenty-two, and in the next twelve years, up to the time of his death, a flow of research memoirs followed, remarkable both in quantity and in the very high standard maintained. In his earlier years he worked in collaboration particularly with Dr. (now Prof.) E. R. H. Jones, and more recently, in studies of hydrogen transfer, with me. He had a number of enthusiastic junior collaborators, including many from overseas. The names of Stern, Timmons, Waight, Jackman and Forbes come to mind. To all his work he brought deep knowledge, sound judgment and enthusiasm, and he was particularly generous in giving helpful advice on other research going forward at the Imperial College.

He was remarkable for the range of his interests. He did valuable work on the synthesis of hydroaromatic and condensed benzenoid systems, particularly in the direction of vitamin D. He was responsible for a new synthesis of thioctic acid. He made important studies of molecular rearrangements, particularly of anionotropy. But he will probably be best remembered for his great knowledge of, and contribution to, the methods of organic chemistry. He discovered the lithium alkenyls and illustrated their synthetic value; he made most significant contributions to the methods of hydrogen transfer processes and their interpretations; and above all he was a master in the application of methods of light absorption to the elucidation of structure and reactions. It was his expert knowledge in this and allied fields which made the book "The Determination of Organic Structures by Physical Methods", which he edited with Nachod, of such great value.

Braude was an extremely clear and conscientious teacher and was in great demand at scientific meetings. He had travelled and lectured in many countries. He was happily married, a most valued colleague and a kind friend. His sudden death at the height of his creative powers, so soon after obtaining a leading academic position, is a matter for profound regret and leaves a great sense of loss.

R. P. LINSTEAD

NEWS and VIEWS

Presidency of the Canadian Association of Physicists : Dr. G. Herzberg, F.R.S.

DR. GERHARD HERZBERG, director of the Division of Pure Physics of the National Research Council of Canada, has been elected president of the Canadian Association of Physicists. Dr. Herzberg was born in Hamburg in 1904 and studied physics at the Darmstadt Institute of Technology. During 1928–30 he did postdoctorate work at the University of Göttingen and at the University of Bristol, and then for five years was an assistant in the Department of Physics at the Darmstadt Institute of Technology. He joined the staff of the University of Saskatchewan as research professor of physics in 1935 and became professor of spectroscopy at the Yerkes Observatory of the University of Chicago in 1945. He returned to Canada three years later as principal research officer with the National Research Council at Ottawa, becoming director of the Council's Division of Physics in 1949 and director of the Division of Pure Physics in 1955. Dr. Herzberg has contributed to the knowledge of the structure of a number of important molecules, including molecular oxygen, molecular nitrogen, carbon dioxide, acetylene and hydrogen cyanide; and he has discovered several new molecules, such as phosphorus nitride and phosphorus carbide. By comparison with his laboratory spectra, it has been possible to establish the presence of certain molecules in planets, stars and in the interstellar space; for example, molecular hydrogen has been detected in the atmosphere of Uranus, and the presence of a diatomic molecular ion consisting of carbon and hydrogen in interstellar space has been demonstrated. Recently Dr. Herzberg and his collaborators have carried out work on the spectra of free radicals. In 1953, he was awarded the Henry Marshall Tory Medal of the Royal Society of Canada "for his achievements in the field of atomic and molecular spectra".

Mechanical Engineering at Sheffield : Prof. J. P. Duncan

MR. J. P. DUNCAN, who has been appointed to the new chair of mechanical engineering in the University of Sheffield, was educated at Scotch College, South Australia, and then at the University of Adelaide, graduating in engineering in 1941. During 1940–46 Mr. Duncan was a student apprentice with Richards Industries, Ltd., a company closely associated with the Chrysler Corporation of the United States. After training in all phases of the company's activities and a period spent in the United States, he afterwards held the executive posts of assistant superintendent of aircraft production and assistant development engineer; in the latter capacity he was for a time solely responsible for the design of post-war motor bodies built in Australia under contract to British and American firms. During 1947–54, Mr. Duncan was on the staff of the University of Adelaide with a primary responsibility for the design and layout of equipment in a new school of mechanical engineering, and in 1954 acted as head of this department. In 1952 he spent one year of study leave in the steam turbine and mechanical research departments of Metropolitan-Vickers Electrical Co., Ltd., and conducted researches into several problems associated with steam power plant, on which he has since published several papers. He returned to England in 1955 as a Turner and Newall Research Fellow for the purpose of extending these researches, and is at present lecturer in mechanical engineering design in the University of Manchester. Mr. Duncan's general interests are in experimental stress analysis, machine design and engineering economy. A special interest is the mechanical design of heat exchangers, in which he is developing optical interference as a method of studying the bending of multiply connected elastic tube-plates.

Acoustics at Newcastle upon Tyne : Prof. E. G. Richardson

DR. E. G. RICHARDSON, who has been appointed professor of acoustics at King's College, Newcastle upon Tyne (University of Durham), has been on its staff for many years. He joined as lecturer in physics in 1931 and became a reader in 1943. During the Second World War, he did important research in acoustics for the Admiralty and in aerodynamics for the Royal Aircraft Establishment. Always interested in the literary side of science, he has written a standard text-book on sound which is now in its fifth edition, together with others on architectural and musical acoustics, ultrasonics and on science for the layman. He is British editor of the international journal *Acustica* and general editor of a large work on technical acoustics, the contributors of which include authorities from most countries of the scientific world. His researches cover a wide field in acoustics, ultrasonics, aerodynamics and rheology, and his published work amounts to about one hundred papers. Prof. Richardson, who has lectured in France, Belgium, Italy and Egypt, has recently returned from the United States and Canada, where he has been attending conferences and visiting acoustic laboratories as a consultant. In his new chair, he is commencing an ambitious programme of research, and at the moment, as holder of a Leverhulme fellowship, is particularly interested in meteorological and marine acoustics.

Department of Scientific and Industrial Research Bill

In presenting in the House of Lords on July 23 the House of Commons amendments to the Department of Scientific and Industrial Research Bill, the Lord President of the Council, Lord Salisbury, said that they are all clarifying amendments relating to Sub-section (3) of Clause 1. The first secures specific mention of technical colleges as places in which the Advisory Council may encourage and support scientific research, and Lord Salisbury said that it has always been the intention of the Government that they should be so covered. The second relates to what may be called, in general terms, development work; and this likewise is intended by the Government to be within the orbit of the new Council, as it is indeed within that of the Department of Scientific and Industrial Research to-day. The third amendment is designed to make it clear that the Council can take account of what is being done elsewhere; although it is not intended or desired that the new Council should attempt to organize and co-ordinate all the scientific and industrial research in Britain, it is intended that, in planning the Department's research programme, the Council should have regard to the total picture of the country's research effort. In commending this amendment, Lord Salisbury also added that, while the amendment should help to ensure that unnecessary overlapping would be avoided, it is left open for the Council to engage in some particular line of research already being pursued elsewhere, if for some special reason it is desirable to do so. The amendments were agreed.

Agricultural Improvement Council for England and Wales

The Agricultural Improvement Council, which recently reached the end of a further three-year period of office, has been reconstituted by the Minister of Agriculture, Fisheries and Food. The Council, which was set up in 1941, keeps under review the progress of research and improvements in technical methods so as to ensure that promising results are applied as rapidly as possible to agriculture and horticulture and to commercial practice in these fields, generally, and advises the Minister from time to time on agricultural and horticultural problems which appear to require scientific investigation and on general policy whereby production may be increased. The reconstituted Council is as follows: Sir Alan Hitchman (*chairman*), permanent secretary, Ministry of Agriculture, Fisheries and Food; Sir Frank Engledow (*vice-chairman*), Drapers' professor of agriculture, Cambridge; Captain J. F. Bomford, farmer and market gardener; Harold Collison, general secretary, National Union of Agricultural Workers; H. R. Finn, farmer, Canterbury; E. Gibby, farmer, Pembroke Dock; Prof. K. Mather, professor of genetics, Birmingham; J. W. S. Mount, horticulturist and farmer, Canterbury; the Duke of Northumberland, landowner and farmer; H. J. Rathbone, chartered land agent, Mold; F. Rayns, director of the Norfolk Agricultural Station, Sprowston; Prof. Ellis J. Roberts, professor of agriculture, Bangor; Sir James Scott Watson, formerly chief scientific and agricultural adviser to the Minister of Agriculture and Fisheries; Sir William Slater, secretary, Agricultural Research Council; H. Cole Tinsley, farmer, Peterborough; Sir James Turner, president, National Farmers' Union; Prof. T. Wallace, director, Long Ashton Fruit and Cider Research Station; and Prof. E. G. White, professor of veterinary preventive medicine, Liverpool. The secretary of the Council is W. Morley Davies, senior education and advisory officer, Ministry of Agriculture, Fisheries and Food, Great Westminster House, Horseferry Road, London, S.W.1.

Tobacco Manufacturers' Standing Committee

The formation is announced of the Tobacco Manufacturers' Standing Committee, composed of representatives of the Federation of Home and Export Tobacco Manufacturers, British–American Tobacco Co., Ltd., and the Imperial Tobacco Co. (of Great Britain and Ireland), Ltd. This development gives formal status to the co-operation in research of the group of manufacturers which in 1954 made a donation of £250,000 to the Medical Research Council for investigation into the causes of lung cancer. Sir Alexander Maxwell will be chairman of the Committee and Sir Alfred Egerton and Sir Ronald Fisher have consented to act as scientific consultants to the Committee in the fields of physical chemistry and statistics, respectively. It is intended in due course to invite authorities on other subjects to serve in a consultative capacity. The offices of the Committee will be at 6–10 Bruton Street, London, W.1.

Technical Education Courses in Britain

In a written statement given in the House of Commons on July 24 about arrangements for regional co-ordination of technical courses and inter-authority payments, the Minister of Education said that he had met representatives of the London County Council and of the Associations of Local Authorities and Education Committees on July 17 and that they had agreed to make certain recommendations to their constituents. In the light of the White Paper on Technical Education and Circular 305 of the Ministry, the local education authorities should invite regional advisory councils to examine urgently the existing provision of vocational courses and to consider how far industry and employers generally are aware of the provision already made for technical education, and how industry and the technical colleges can be better informed of any decisions resulting from a regional advisory council's advice which may affect the pattern of future development and particularly the planning of new advanced vocational courses. A working party of officers of the Ministry, H.M. inspectors, representatives of local authorities and education committees (including representatives of technical colleges), representatives of industry and officers of regional advisory councils should be set up to consider procedure for examining and approving, in the first instance, technical education courses. Authorities should give automatic consent to the attendance of students at any advanced courses at a designated college of advanced technology outside the area in which they reside and also in respect of attendance at any other course in a designated college or elsewhere, except where an authority finds it desirable to require prior consent. The Minister and the regional advisory council concerned should be informed of the exceptions. Automatic consent may be withdrawn if, in the authority's opinion, the student's attendance or progress is unsatisfactory. Local education authorities should review the composition of governing bodies of technical colleges to ensure that they include appropriate representation of authorities from whose areas substantial numbers of out-county students are drawn.

International Radio Consultative Committee

THE eighth plenary assembly of the International Radio Consultative Committee (C.C.I.R.) was formally opened in Warsaw on August 9, to study various technical problems encountered in the practice and development of radio communication, with the view of making recommendations to be submitted to the International Telecommunications Union (I.T.U.). The work of the Committee is organized under fourteen study groups, which are meeting during the period August 10–31, after which the full assembly will discuss the various recommendations and study programmes with the view of their adoption as a guide to future progress in the radio field. The United Kingdom delegation is led by Captain C. F. Booth, assistant engineer-in-chief, General Post Office, accompanied by seven other delegates of the Post Office staff, and one each from the Department of Scientific and Industrial Research and the Ministry of Supply. The delegation also includes technical advisers of the Radio Industry Council and representatives of the organizations operating radio services in Britain. Two members of the delegation are the international chairmen of study groups, namely, Dr. R. L. Smith-Rose (Study Group V), on tropospheric wave propagation, and Mr. H. Stansby (Study Group IX), which deals with general technical questions.

Among the subjects of particular scientific interest under discussion are those of radio wave propagation over the ground and through the troposphere and ionosphere, atmospheric noise in various parts of the world, radio time signals and standard frequencies and various aspects of broadcasting and television. Adequate liaison arrangements have been established between the International Radio Consultative Committee and the International Scientific Radio Union (U.R.S.I.) for the study of subjects of mutual interest, with the general objective of improving the efficient and economical use of the radio-frequency spectrum for all practical and scientific purposes.

World Resources in the Immediate Future

THE spring issue of *Progress*, the magazine of Unilever, Ltd., includes the last of a series of articles surveying world resources which Sir Solly Zuckerman has edited during the past five issues. The series was introduced by Sir Solly himself in the spring issue of 1955 with an article in which he outlined broadly the problem presented by the rapid growth of world population and the consequent growing demand for capital and consumer goods and higher standards of living. In following articles M. John considered, first, world supplies of power and water and then those of land and food, and finally of raw materials, setting out in broad terms the main material considerations that are likely to determine the development of industry over the next two or three decades. In this final article on the social and political aspects, Sir Solly Zuckerman agrees that no shortage is likely to develop capable of defeating human ingenuity; but he believes that the unequal division of resources between 'have' and 'have-not' countries is the core of a social challenge steadily growing more urgent with the rapid increase in the populations of the under-developed countries of the Eastern world. The price of peace may well be the sharing of resources, and if the British are not to lose by the sharing they must remain constantly alert to the challenge of new industrial technologies and to the possibilities of creating greater wealth.

The Imperial Forestry Institute, Oxford: Report for 1954–55

THE thirty-first annual report for 1954–55 of the Imperial Forestry Institute, Oxford, to which is attached the University School of Forestry (pp. 32; from the Institute, 1956), points out that in 1955 the School celebrated its fiftieth year, having been brought to Oxford by Dr. Schlich when the Royal Indian Engineering College, Coopers Hill, was closed in 1905. The Forest Herbarium, though still housed in the Botany Department, has now been transferred back to the School of Forestry. The number of students attending courses during the year was fifty-eight. Fourteen were successful in the examination for their forestry degrees; and of these, two were Colonial forest probationers who returned to their Colonies, two obtained posts in the Colonial Forest Service, one returned to Pakistan to join the Forest Service there, a South African obtained a post in the Northern Rhodesian Forest Department, and another two went to Canada before returning to South Africa. One government scholar from each of Kenya and Jamaica returned to join their respective forest departments. One graduate joined the Oxford University Expedition to Borneo as botanist, and four joined up for National Service. This enumeration furnishes ample evidence that the Institute has fully justified its inauguration, the more so since many parts of the British Colonies will in future be more or less dependent upon it for maintaining the requisite professional knowledge in the staffs of their departments. The forest officers' course at the Institute was attended by twelve officers of the forest services of various Colonies. The sections dealt with in the report are sylviculture, ecology, tree physiology, forest botany, forest pathology, forest entomology, mensuration, aerial surveys, statistics, forest economics, forest law, Colonial forest administration, forest protection, surveying and the library.

Agricultural Research in India

A BRIEF account of research and agriculture in India under the Second Five-Year Plan is given in the April number of *Science and Culture* by M. S. Randhawa. Out of Rs. 350 crores for the Central and State research and development schemes, Rs. 38 crores is for direct expenditure by the Central Government. The production and distribution of nitrogenous fertilizers is to be increased to three times the present level of 600,000 tons a year, and a scheme is proposed for the distribution of improved seeds through a network of seed farms, each serving a group of a hundred villages. Large-scale developments are proposed for cattle, sheep and poultry, including an additional three hundred artificial insemination centres and six hundred extension centres for which more than thirty thousand bulls will be required, including 4,200 of known pedigree and productive capacity. Rinderpest is to be eradicated by planned mass-scale vaccination of all cattle throughout the country, and by 1961 the National Extension Service for extending knowledge to the farmer will cover the entire country. In regard to research, Dr. Randhawa stresses the importance of radiobiology, particularly radiogenetics, and the exploitation of hybrid vigour, notably hybrid maize, sorghums and vegetables, and also hybrid poultry and pigs. Provision has also been made for the establishment of two horticultural plant introduction stations at Saharanpur and Hasarghatta; a Division of Horticulture is being established at the Indian Agricultural Research Institute at a cost of Rs. 11,29,000, and regional research is projected on mango, citrus, grapes, guava, apples and pineapples.

Farming Advisory Services in North America

IN 1955 a mission, sponsored by the Nuffield Foundation, visited the United States and Canada to study the farming and advisory services in order to gain ideas for increasing the efficiency of the agricultural advisory work in England and Wales. Its report, "Farming Advisory Services in North America", has now been published (pp. 53; from the Nuffield Lodge, Regent's Park, London, N.W.1; 1956; 4*s*. 6*d*.). While fully recognizing the different physical, economic and social factors that influence farming in North America and Great Britain, the report suggests certain changes in the organization of the National Agricultural Advisory Service based on American 'extension' experience. It recommends "that serious reconsideration should be given to the desirability of making it (as in Scotland) an extramural activity of university schools of agriculture. Removal from direct government control would help to give the service a better professional status and to increase the farmer's confidence and co-operation". More encouragement should also be given to developing local interest. To this end, county and rural district councils might contribute to the cost of the service and more use made of the district office, now in danger of being closed. Programme planning with later assessment of results, carried out at the local level, could be a further means of promoting co-operation between the advisory officer and the farming community. The issue of supervised loans at low interest-rates to low-income farmers, similar to those provided under the Farmers Home Administration in the United States, is another suggestion put forward; but it is made clear that the responsibility of any such scheme should not be with the Advisory Service. In conclusion, much of the success of the American 'extension' was felt to be due to the prevailing spirit of confidence, both in itself and between the service and the farmer.

Datura Research Material

THE Smith College Genetics Experiment Station was discontinued at the end of 1955, a year after the death of Dr. Albert F. Blakeslee, its founder and director since 1942. For many years the investigations of Dr. Blakeslee and his colleagues at Smith College, and earlier at the Department of Genetics of the Carnegie Institution of Washington, had been concerned with the genetics of *Datura*. As a result of this work, tetraploid, as well as diploid, lines of most species as well as chromosomally different races are available. The National Science Foundation has recently made a grant to Smith College to finance the assembling of the data on the genetics of *Datura* and related problems, and its publication in a monograph on *Datura*. This will be in charge of Amos G. Avery, and the principal contributors will be Dr. Sophie Satin and Dr. J. Rietsema. Seed of all the species and of most of the races and types have been grown and placed in controlled cold storage. These are available to any investigator who desires to continue some aspect of research on *Datura*. Application should be made to Dr. H. H. Plough, Amherst College, Amherst, Mass., indicating the seeds desired and the general nature of the investigation planned.

Cell Mounts for Biological Materials

IN an article in the *Museums Journal* (November 1955), Mr. C. V. Adams, of the City Museum, Plymouth, discusses the use of cell mounts as an alternative to embedding biological specimens in transparent plastic. It is maintained that the use of plastic entails several stages in the work and that specialized skill and a fair amount of time are necessary. In cell mounts the material may be mounted in formalin, alcohol or in the dry state. The last is especially useful as it enables many of the Lepidoptera to retain their colour, which is often lost in an embedding process. The mount consists of a transparent polystyrene lid which fits on to the flange of a polystyrene base-plate. The base-plate can be obtained in black, white or completely transparent, and the entire mount measures 2¾ in. × 1½ in. × ½ in. When used with a liquid mount, the cell is capable of holding 40 c.c. of preservative. The lid is welded to the base by 'Cristalite'. The cell mounts can be obtained from P. K. Dutt and Co., Ltd., of Alfred Place, London, W.C.1.

Production and Transport of Liquid Methane

AT a recent meeting of the Institution of Gas Engineers, J. Burns and L. J. Clark considered the economics of liquid methane derived either from methane itself or natural gas in association with oilfields (Publication No. 484 of the Institution; pp. 22; 1956). It is argued that, in the Middle East alone, more natural gas is being burnt to waste than would be needed to meet the total requirements of the British gas industry. Regarding sources of supply to Great Britain, the Middle East, Mexico and Venezuela are potential areas since reserves are vast and comparatively unexplored, reasonably near seaports and, at present, subject to limited local demand. The chief problem is trans-ocean transport of the liquefied gas which, incidentally, only occupies 1/600 of its volume in the gaseous state. It would require the construction of liquid methane tankers capable of carrying this fluid at sub-zero (Fahrenheit) temperatures; such tankers would have to be of at least 35,000 tons and would be at least double the cost of conventional oil tankers. Storage conditions and costs would also be considerably higher than for oil; further, distribution would be restricted to industrial areas where deep-water facilities are available.

Scottish Soil Survey

THE fourth memoir to be published of the Soil Survey of Great Britain, and the second concerning Scotland, has appeared under the title "The Soils of the Country round Jedburgh and Morebattle" (pp.

178. Edinburgh: H.M.S.O. 30*s*.). The area surveyed embraces Sheets 17 and 18 of the 1 inch/1 mile Geological Survey of Scotland. Sheet 18 comprises only a small corner of Scotland, the rest being left blank, presumably to be completed in due course by the Soil Survey of England and Wales. It would have been more convenient for the user and more economical in the printing of the map if the two constituent parts of the Soil Survey of Great Britain had collaborated to produce two complete sheets of this border country instead of each separately producing two incomplete sheets. The memoir caters for the needs not only of the soil specialist, but also of the land user, the country planner, and students of ancillary sciences such as geology and ecology. The work of combining these many points of view has been well executed, and has produced a very readable account of the physical environment of the district. The main soil associations and series are adequately and concisely described and their relationships to local types of agriculture are indicated. Data of mechanical and chemical composition are given in an appendix. The soil maps are excellent, and many beautiful photographs, not all of which are illustrative of the soils, are included. In some respects the memoir has been produced with unnecessary extravagance, which is reflected in the price.

International Conference in Munich of University Teachers

The ninth conference of university teachers, organized by the International Association of University Professors and Lecturers, will be held in Munich during September 3–8, under the chairmanship of Prof. Francesco Vito. The aim of the conference is to discuss problems fundamental to universities throughout the world. In particular, the following topics will be considered: the scientific and social responsibilities of the university teacher in relation to his academic independence, and the effect of these responsibilities and of the pressure of non-teaching and outside work on a proper fulfilment of his task; the maintenance of a university tradition and the training of future university teachers; the conditions of employment and the contractual obligations of university teachers working in countries other than their own; scientific research in the universities and its relations with industrial research; the status and careers of research workers and those engaged in the social sciences; the place of classical studies and the humanities in a general education. The conference is open to all university teachers, whether members or not of the Association. Further information can be obtained from the Secretary, International Association of University Professors and Lecturers, 21 Dawson Place, London, W.2.

Oversea Service Division, Colonial Office

The following appointments have recently been made in the Oversea Service Division, Colonial Office: C. Yates (inspector of works, Public Works Department, Nigeria), chief supervisor of forest works, Forestry Department, Sierra Leone; W. A. Dos Santos (pathologist, Trinidad), pathologist, Federation of Nigeria; D. J. Bargman (meteorologist, East African Meteorological Department, East Africa High Commission), regional representative (Uganda), East African Meteorological Department, East Africa High Commission; C. J. Cartledge (meteorological assistant, Nyasaland), meteorological assistant, East African Meteorological Department, East Africa High Commission; J. P. Henderson (assistant director, East African Meteorological Department, East Africa High Commission), deputy director, East African Meteorological Department, East Africa High Commission; D. McCullum (meteorologist, East African Meteorological Department, East Africa High Commission), regional representative (Tanganyika), East African Meteorological Department, East Africa High Commission; B. W. Thompson (meteorologist, East African Meteorological Department, East Africa High Commission), regional representative (Kenya), East African Meteorological Department, East Africa High Commission; Dr. I. E. M. Watts (assistant director of Malayan meteorological services, Singapore), director of the Royal Observatory, Hong Kong; D. O. Mill (senior statistician, Jamaica), deputy director of statistics, Jamaica; Dr. D. E. L. Rollinson (chief veterinary research officer, Uganda), assistant director of veterinary services (research), Uganda; T. G. C. Vaughan-Jones (director of game and tsetse control, Northern Rhodesia), commissioner for rural development, Northern Rhodesia; D. I. Allen, agricultural engineer, British Guiana; R. M. Veevers-Carter, assistant fisheries officer, Aden; R. W. Bartholomew, geologist, Fiji; E. B. Wolfenden, geologist, Sarawak; M. J. Glover, scientific officer (West African Stored Products Research Unit), Federation of Nigeria; L. E. Stephen, senior scientific officer, West African Institute for Trypanosomiasis Research, Nigeria; P. F. Byrne, veterinary officer, British Guiana; H. Steding-Jessen, veterinary officer, Gold Coast; K. S. Thomson, veterinary officer, Tanganyika.

Announcements

Dr. D. G. O. Morris, senior lecturer at the University College of North Wales, Bangor, has been appointed to the University of London readership in electrical engineering tenable at the Imperial College of Science and Technology.

The culture collection of bacterial plant pathogens built up by Dr. W. J. Dowson (who retired in 1952 from the staff of the Botany School, Cambridge) has now been transferred to the Plant Pathology Laboratory of the Ministry of Agriculture, Fisheries and Food, 28 Milton Road, Harpenden, Herts, where it will be in the care of Mr. R. A. Lelliott. Dr. Dowson is continuing his researches on various aspects of plant bacteriology at the Botany School, Cambridge.

Two fellowships have recently been awarded by the Mental Health Research Fund, the first of which, a Leverhulme fellowship of a total value of £3,600, tenable at the Department of Anatomy, University College, London, is to Dr. Brian G. Cragg, to continue his research on the function of the hippocampus. The other award is a Mental Health Research Fund fellowship, of £900 a year for two years, to S. Folkard, who is working at the Netherne Hospital, Coulsdon, Surrey, on an assessment of the contribution which social science techniques can make to the diagnosis and treatment of patients in a mental hospital. The Mental Health Research Fund will be offering further fellowships for competition during the coming year.

Erratum. In the article entitled "Growth and Sexual Maturity in Aquatic Mammals", by Dr. R. M. Laws, in *Nature* of July 28, p. 193, the lengths quoted in Table 1 should be "in feet" for the Cetacea and "in inches" for the Pinnipedia.

ROYAL GREENWICH OBSERVATORY

ANNUAL REPORT FOR 1955–56

THE annual report of the Astronomer Royal for the period April 1, 1955–March 31, 1956*, deals with the Royal Greenwich Observatory under three headings: Greenwich and Abinger; Herstmonceux; and Hartland.

As no major overhaul of the Yapp 36-in. reflector had taken place since its erection, it was decided to dismount it earlier than the progress of its dome at Herstmonceux would otherwise have justified, and to use the poor observing months in reconditioning it, repainting the structure and re-wiring where necessary. The repainting was largely completed by the end of the year under report, but the re-wiring remains to be done. Defects of the figure in the main mirror were referred to in the 1954–55 report, and it was decided to dispatch the mirror to the firm of Sir Howard Grubb, Parsons and Co., Ltd., for the removal of these defects.

Observations of the four bright minor planets for position have been continued with the astrographic refractor, and reductions of the plates are well advanced. Investigations on the systematic errors of deduced place due to photographing well away from the meridian were carried out by exposures in three-star fields at widely different declinations, and most of the thirty-nine hour-angle plates taken during the year have been measured and reduced. The magnitude and sign of the effect vary with the declination of the test field in such a way that the small displacements found cannot easily be attributed to such effect as flexure. It is impossible to interpolate to other declinations so long as a physical explanation is lacking, but it is not considered likely that the effect can appreciably influence astrometric work except in the few cases where large ranges in hour-angle are deliberately employed, for example, in single-station parallax work on minor planets. Some test plates taken by Dr. D. W. Dewhirst with the new 17/24-in. Schmidt camera of the Cambridge Observatories have been examined to find whether the optically similar instrument planned for Herstmonceux will be suitable for astrometry.

In accordance with the recommendations of the International Union of Pure and Applied Physics, recording of the general ionizing flux under 10 cm. of lead has been done without any significant interruption, and the diurnal and other variations have been investigated. The cosmic-ray flare of February 23 last was recorded, showing more than 100 per cent increase; observatories throughout the world are supplying information on this remarkable flare (see *Nature*, July 21, p. 125).

Routine observations with the Lyot birefringent $H\alpha$ filter on the $6\frac{1}{4}$-in. Newbegin refractor started on June 13, 1955, and on 175 days out of the 293 days up to March 31 daily photographs were taken of the Sun's disk and of the prominences visible at the Sun's limb. Also, special series of photographs were taken on about twenty-five occasions during periods of flare-activity on the Sun. The photographs were taken on red-sensitive 35-mm. film specially provided by Kodak, Ltd.; the film, which is of fine grain, requires an exposure of about $\frac{1}{5}$ sec. under favourable sky conditions. The image-size is approximately 21 mm. to the solar diameter, and the photographs normally reveal details down to a size of 5″ of arc. The firm of Kodak, Ltd., has taken considerable trouble to produce a suitable film, and various difficulties experienced with the film have been overcome.

Among the numerous matters dealt with in the report is a short account of the Electronics Laboratory in which experimental work on operating a quartz-crystal oscillator with the resonator at the temperature of liquid hydrogen has been carried out at Oxford with the help of the Clarendon Laboratory. The experience derived has suggested modifications in both the low-temperature and the electronic-measuring equipment, and results obtained are so promising that it is intended to continue these experiments. Acting on the request of Study Group 7 of the International Radio Consultative Committee to investigate the possibility of high-accuracy frequency comparison by means of the 16- and 60-kc./s. controlled transmissions from Rugby, experimental equipment for continuous recording of the phase of these transmissions has been built, and an accuracy of a few parts in 10^{10} has been achieved. This method of frequency-checking possesses such accuracy and simplicity that it has been chosen for the next series of tests at Oxford.

At Abinger the routine work has continued, and it is intended that this Station will continue to provide data throughout the International Geophysical Year. The building of the new magnetic observatory at Hartland was commenced in the early summer of 1955, and it is expected that it will be operating by the late summer of this year.

The routine calculations and proof-reading in the preparation and printing of the publications for which the Nautical Almanac Office is responsible have been continued as usual. It has been agreed that the "Abridged Nautical Almanac" and the "American Ephemeris and Nautical Almanac" shall become identical, beginning with the 1958 editions. The unification of the two publications has required a number of changes in both, but as complete agreement has been reached on the numerous details of presentation, most of the copy is now ready for photographic reproduction. Among the ramifications of the work of the Nautical Almanac Office may be mentioned the prediction of occultations of radio sources by the Moon. The predictions are at present restricted to the twenty-six radio sources of the second Cambridge survey with a flux density not less than 50 units within the zodiacal band, the unit being 10^{-26} W. m.^{2} (c./s.)$^{-1}$. The predictions are sent in manuscript form direct to the radio stations: those for July–December 1955 were sent to eight stations, and those for January–July 1956 to fourteen stations.

---

* Report of the Astronomer Royal to the Board of Visitors of the Royal Greenwich Observatory. Pp. 25. (Herstmonceux: Royal Greenwich Observatory, 1956.)

It has been decided that the duplex design for the Isaac Newton telescope be abandoned and that attention be concentrated on the construction of a conventional paraboloid telescope. A committee is working out a detailed design on this basis, and substantial progress is reported.

ONTARIO RESEARCH FOUNDATION

REPORT FOR 1955

THE annual report of the Director of Research of the Ontario Research Foundation for 1955* refers to additions to the duties and responsibilities of the Foundation in consequence of the termination of the Research Council of Ontario. The Foundation is now authorized to spend 50,000 dollars a year on scholarships and fellowships for postgraduate students in science, and for the year 1955–56 forty-one scholarships were awarded. The estimates also provide for grants of 145,000 dollars to universities and colleges in Ontario for postgraduate research in the natural sciences and engineering, and sixty-four such grants were made for 1955–56. The advisory committees for research in fisheries and wild-life and in forestry and forest products and for industrial research have been reconstituted, and their membership is given in an appendix. The Director again notes the growing difficulty in recruiting an adequate number of Canadian graduates with the requisite scientific background and character and also the need for further space and equipment, particularly for pilot-plant operatives in the Metallurgy and Chemistry Departments in view of the growth of the Foundation's activities over the past ten years, during which its income has increased from 364,385 dollars in 1945 to 1,014,086 dollars in 1955.

The Biochemistry Department has achieved further success in modifying chemically a lignin sulphonic acid phenol condensate and applying it in tanning heavy leather, and it is hoped that the Department will be able to re-examine potential sources of vegetable tannins in Canada. Workers under the Rice Mills Fellowship have met with continued success in the production of humidifier plates from rice hull ash, and they are now engaged in a study of experimental lots of acoustic tile. Besides co-operative work with other Departments, the infra-red laboratory has been used by eight companies in their own investigations. A close correlation has been noted in the oils and fats laboratory between the tendency of an oil to deteriorate and its ability to react with 2-thiobarbituric acid, and fodder yeast has been produced from cheese whey by a simple process.

The Department of Chemistry, using improved methods of paper chromatography, has determined quantitatively the nine lower members of the phosphoric acid series and occasionally up to the twelfth member, and has continued its work on phosphate glasses. It is proposed to concentrate the work of the air pollution laboratory on careful analysis of the atmosphere in relation to climatic conditions, and on a determination of the organic constituents and the ozone concentration. A commercial model has been constructed which is able to check accurately sixty piezo-electric quartz crystal units per hour. A study of the viscosities of grafted copolymer solutions showed that the viscosity increases rapidly as the shear-rate decreases for branched copolymers, but is unaffected for linear copolymers. The electroplating laboratory has found that large inclusions in commercial steel could be an important source of failure for nickel deposits of the order of 0·0001 in. thickness from a low-pH Watts bath. Work on the utilization of waste sulphite liquor continued.

The volume of work in the Engineering Section of the Department of Engineering and Metallurgy is two and a half times that in 1954. Pilot-plant work in the research on controlled-density steel has yielded important results on the economics of the process, furnace design and the production of the reducing gas; work in the ferrous metallurgy laboratory included the chemical production of pure magnetite, the decrepitation of ores at various temperatures to improve concentrates, the design and construction of improved magnetic separators, particularly for handling extremely fine particles, and the design and construction of a machine for pelletizing iron ore concentrates. Fundamental work in the physics of metals is aimed at acquiring new knowledge about the fatigue process and applying this knowledge to discover new materials of high fatigue strength, as well as developing tests to measure fatigue damage. In the X-ray laboratory a helium bath has been obtained and the range of the X-ray spectrographic analysis has been extended to elements of lower atomic numbers.

In the Department of Parasitology, work continued on the blood protozoa in birds; and tests on the antimalarial drugs 'Daraprim', 'Camoquin' and 'Aralen' against *L. simondi* in ducks showed that 'Daraprim' prevented parasitæmia, but neither of the others had any prophylactic or therapeutic value. The investigation of the life-history of two species of flukes that occur in foxes and other carnivores was completed; 30 per cent of almost a thousand nests of forty-five species of birds examined were infested with thirteen different species of *Protocalliphora*. In the Department of Physiography laboratory work was completed on minerals in the colloidal fraction of glacial tills and water-laid clays in southern Ontario, and a study was made of climate for peaches in Ontario. The Textile Department is concentrating its resources on short-term work in the immediate future, and undertaking only one or two fundamental problems, including the physical properties of viscose yarn and the resistance of nylon to immersion in water and exposure to light.

RESEARCH ON ANIMAL PRODUCTION

THE British Society of Animal Production was established towards the end of the Second World War for the purpose of bringing together those interested in both the science and practice of the breeding, feeding and management of farm animals, and the recently published volume of its Proceedings for 1955* contains many interesting and important papers on current research in animal production. The following examples indicate the wide range of the problems under investigation by many different workers throughout Great Britain.

---

* Proceedings of the British Society of Animal Production, 1955. Pp. 122. Edited by I. L. Mason and G. Wiener. (Edinburgh and London: Oliver and Boyd, Ltd., 1956.) 15*s*.

Work at the University College of North Wales, Bangor, shows that the weight of the lamb in hill sheep in September is probably the best single guide to adaptation and production, for this shows the best correlation with adult weight and has a heritability of 0·68 ± 0·06. From the rumen contents of hill sheep in Scotland the selective grazing on heaths and heathers in different months has been assessed. In fast-growing suckling lambs implantation of œstrogen caused but little increase in live weight, but reduced carcass fat and caused some cases of vaginal prolapse. By comparing worm-free lambs with those artificially infected, the depression of live weight and wool growth was measured and a method of grazing management to prevent infection is described. Under similar management, for each additional pound at birth a difference of 2–4 lb. may be expected in lambs at weaning.

A pasture-sampling method for the estimation of daily dry-matter intake of grazing animals is described, and this was used for measuring the intake of cows in different circumstances. The management necessary to prevent pregnancy toxæmia in sheep is described. In field trials flock fertility was increased by treatment of the ewes with pregnant-mare serum hormone. The time onset of bloat in cattle and its severity are affected by pasture conditions, rate of grazing and previous feeding. Free-range grazing of pigs allows them to select young leafy leguminous growth, while close folding restricts selection, so that in summer free-range grazing effects a saving of 32 per cent of a medium protein meal whereas close-folding saved only 8 per cent.

From an analysis made of the progeny tests of bulls in different herds, it is concluded that within a breed only a small fraction of the difference between herds in milk yield is genetic, but that for fat percentage the fraction is rather higher. In medium- and high-producing herds the first lactation record is superior to the second as an indication of the cow's inherent capacity for yield. By applying magnesium sulphate to grass intended for silage, the magnesium content of the blood of the cattle consuming it was raised, but dropped again when they were turned out to young grass, showing that no body reserves of magnesium are built up.

If the present standard of this publication is maintained, it will prove to be an important contribution to the literature on animal production by presenting in a concise manner an up-to-date account of research work in progress.

MULTIPLE FIRING AT CENTRAL SYNAPSES

By Prof. A. K. McINTYRE, R. F. MARK and J. STEINER

Department of Physiology, University of Otago, Dunedin

ELECTROPHYSIOLOGICAL investigations in which penetrating microelectrodes have been used for recording action in the central nervous system have led to a number of reports of single neurones discharging repetitively in response to brief peripheral stimulation[1–5]. In most of these and other similar reports little attention has been paid to this synaptic peculiarity, despite the fact that little or no such repetitive postsynaptic firing occurs in the most intensively studied central synaptic system, the spinal stretch-reflex arc[6,7]. Exceptions are the papers of Bishop, Jeremy and McLeod[8] and of Rose and Mountcastle[9], in which the phenomenon of multiple firing was singled out for study, in the lateral geniculate and thalamic afferent relay systems respectively.

In our own microelectrode studies during the past three years, neurones firing repetitively in response to single-shock presynaptic stimulation have been frequently encountered. These stand in striking contrast with motoneurones, which scarcely if ever discharge more than once to similar stimulation of the monosynaptically-connected afferent fibres of the stretch-reflex arc. The contrast is illustrated in Fig. 1, which displays responses of single units in various parts of the nervous system, each recorded by way of a Ling–Gerard type glass micropipette[10]. The typically single monosynaptic discharge of a motoneurone is shown in *A* ; multiple responses of other neurones are illustrated by records *B–F*, the details of which are explained in the legend. Examples such as these suggest that the behaviour of motoneurones, upon which so much of our present knowledge of synaptic mechanisms is based, so far from typifying synaptic action generally, actually represents an exceptional case.

The synaptic system which in our hands has proved most favourable for experimental analysis of the multiple firing phenomenon is the relay from lumbosacral primary afferent fibres to second-order neurones the axons of which course headwards in the dorsolateral tract. In earlier studies of the whole tract response, prolonged, irregular firing after the initial nearly synchronous tract discharge was noted[11,12], but it was not certain until unit responses were obtained, such as those of Fig. 1 *B*, whether individual tract fibres actually fired more than once. Our experiments have now revealed that many of the fibres do behave in this fashion, and the form of the whole tract after-discharge is adequately explained by summation of the responses of many repetitively-firing fibres.

The experimental advantages of the dorso-lateral tract synaptic relay can be summarized as follows. The tract fibres are large, and, lying superficially during most of their course in the spinal cord, are well suited both for recording and direct stimulation. Thus their responses to presynaptic action can be studied with the recording electrode remote from the actual synaptic region, which we have found to be extremely vulnerable to injury even by the finest electrodes. Furthermore, antidromic volleys can be readily set up in the tract fibres, a matter of considerable technical difficulty in many of the other central synaptic systems of like behaviour. Because of these favourable features, it has been possible to obtain new evidence bearing on the mechanisms responsible for repetitive firing. Our results will now be considered in relation

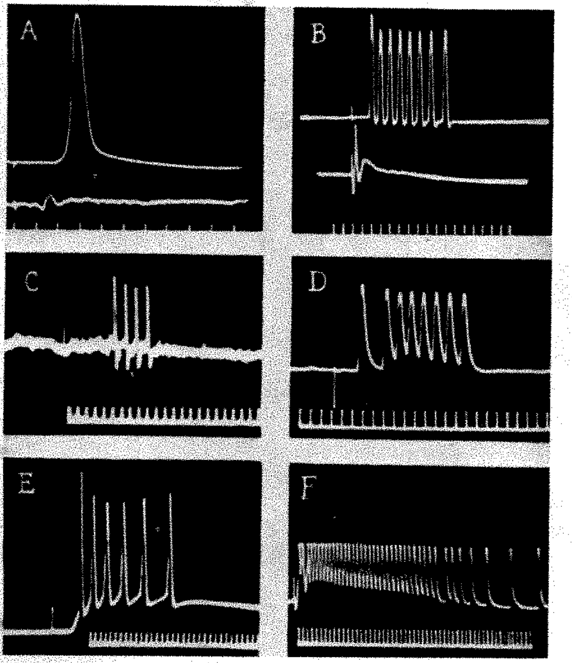

Fig 1. Discharges recorded from units in different parts of the central nervous system by means of Ling–Gerard micropipettes. The top record in *A* is the monosynaptic discharge, recorded intracellularly, of a hamstring motoneurone in response to a volley in the combined biceps and semitendinosus nerves. The upper trace in *B* is the response of a single dorso-lateral tract fibre to a stimulus applied to the ipsilateral seventh lumbar dorsal root. The lower beams in each case display the afferent volley at its entry into the spinal cord. *C* shows the response of a cell in the cuneate nucleus to a single volley in the superficial radial nerve. *D* that of a spinal cord internuncial to single-shock stimulation of a lumbar dorsal root. *E* illustrates the firing of a neurone in the cerebral cortex (somatic sensory area) elicited by a single stimulus to the medial lemniscus in the medulla. *F* shows the discharge of a Renshaw cell in the ventral horn of the seventh lumbar segment in response to a single volley in the corresponding ventral root. All records from cats under barbiturate anæsthesia. Time marks show millisecond intervals

to various possible explanations which might be advanced to account for the phenomenon.

Injury discharge. In most of the earlier reports, the potentials were recorded from postsynaptic cell bodies, and it is possible that slight electrode damage to a cell, normally responding singly, might create a tendency to repetitive discharge, a common effect of injury. Records such as the one shown in Fig. 1 *B* effectively dispose of the notion that electrode damage to cell bodies is a necessary requirement for such synaptic behaviour, since the discharge was recorded from a tract fibre, the actual synaptic region being quite undisturbed. The possibility of the fibre itself being in a similar abnormal state through electrode damage is precluded by the observation that direct tract stimulation gives but a single (antidromic) response.

Temporal dispersion of primary afferent volley. Simple temporal dispersion of impulses ascending primary afferent fibres in the dorsal funiculus undoubtedly occurs, especially in fibres of small and intermediate size-range. Since convergence of such fibres (especially from skin receptors) on to dorso-lateral tract units has been demonstrated[13], such dispersion could lead to the impingement upon individual second-order neurones of a prolonged shower of presynaptic impulses. Were this the sole explanation, latency of the first discharge would be expected to remain relatively independent of volley size, being largely determined by conduction time in the largest, lowest-threshold afferent fibres making synaptic contact. This, however, is not the case, latency being much longer with small than with large presynaptic volleys. Furthermore, reduction of temporal dispersion by stimulating the afferent fibres in the dorsal column near the site of synaptic relay does not substantially reduce the repetitive firing. Though such dispersion may contribute to the after-discharge mechanism, we do not think it can account fully for the phenomenon.

Repetitive action of presynaptic fibres. The 'dorsal column relay' of Hursh[14] could prolong presynaptic action by causing repetitive firing of individual primary afferent fibres. However, the phenomenon is sensitive to temperature, and since we have not detected any clear-cut change in tract discharge patterns at different cord temperatures, it does not seem likely to be an important factor.

Internuncial activity. The most popular hypothesis at the present time postulates the operation of internuncial delay-paths[15] to account for the prolongation of action. In one specific form of this hypothesis, collaterals from the principal postsynaptic neurones constitute the first link in the recurrent chain[8]. Our observations have definitely excluded this particular scheme, at least for the dorso-lateral tract relay, for should it be operative, antidromic conduction of impulses by tract fibres would also lead to their firing repetitively, and this, as stated already, does not occur. It is difficult to obtain unequivocal evidence of the possible role of purely presynaptic delay-circuits. Nevertheless, it may be doubted whether internuncial activity could bring about discharges of such striking regularity and rapidity. In the case of the classical flexor reflex, in which internuncial chain activity certainly figures prominently, the successive bursts of polysynaptic bombardment impinge on flexor motoneurones with less regularity and at a slower rate[16] than, for example, the discharge shown in Fig. 1 *B*. Furthermore, in preliminary experiments it has not been found possible to abolish the repetitive firing with the powerful internuncial depressant, myanesin. The repetitive discharge of Renshaw interneurones[3,5] may be cited as a further indication that prolonged postsynaptic activity may occur in the absence of repetitive presynaptic action. There is no evidence that internuncial chains are involved in the activation of these cells by recurrent axon collaterals, yet a synchronous ventral root volley coursing antidromically for a few centimetres at most can bring about remarkably rapid and prolonged firing (Fig. 1 *F*).

At present, therefore, we incline to the view that explanations based on repeated bombardment of second-order neurones by presynaptic impulses cannot account fully for the phenomenon of multiple firing. Prolonged transmitter action exerted by individual impulses in the presynaptic terminal ramification appears to us a more likely hypothesis.

Whatever the exact presynaptic mechanism may be, the ability of the postsynaptic cells to fire so rapidly in response to sustained excitation calls for comment, in view of the failure of motoneurones to discharge repetitively at a fast rate even with repeated presynaptic excitation. Powerful depolarizing pulses applied directly to the motoneurone membrane can evoke several impulses in rapid succession[17], but excitability soon fails, and sustained firing at rates such as those seen in Fig. 1, *B–F*, does not occur. One suggestion which can be advanced to account for this difference is that neurones capable of sustained rapid firing are so organized that impulses do not invade regions of slow recovery such as the dendrites[18]. According to this view, the transmitter agent brings about in postsynaptic dendrites a long-lasting depolarization which acts as a generator potential evoking repeated discharges in the cell body and axon, much as described by Kuffler and Eyzaguirre in crustacean stretch receptor neurones[19].

As to the significance of the multiple firing phenomenon, its prominence in afferent nuclear relays suggests that it might play an important part in the neural processes underlying sensation. It is conceivable that temporal expansion of afferent signals could act as a matching device between receptors and higher centres. However, the extensive convergence of primary afferent fibres on second-order neurones suggests other possibilities. Since recruitment of additional converging afferent fibres to the presynaptic volley commonly leads, not to occlusion, but to an increase in the number of postsynaptic impulses discharged, the multiple firing mechanism provides a means of converting a spatial pattern in primary afferent fibres into temporal patterns of impulses in individual second-order neurones.

The studies on which this report is based were supported by a grant from the Medical Research Council of New Zealand.

WATER ECONOMY OF TROPICAL MERINO SHEEP

By Prof. W. V. MACFARLANE, R. J. MORRIS and B. HOWARD
Department of Physiology, University of Queensland

NEARLY eight million sheep live on unshaded plains in tropical Australia. Since May 1954, we have studied the thermal adaptation of merinos at Julia Creek, Queensland, 21° S. lat. and 142° E. long. Summer ambient temperatures reach 46° C. (115° F.), and for six months the mean monthly maximum temperature is above 35° C. (95° F.). For the three winter months, temperatures range from 0° to 25° C.

The water intake, output and distribution of sixty young merinos have been followed through two winters and two summers. The sheep have proved physiologically hardy and well adjusted to extremes of heat, water supply and nutrition. They normally lived on the native pasture; but they were trained to feed on native grass hay and maize in yards. In the yards mean winter water intake over 120 sheep-days was 7·3 ml./kgm./24 hr.; and in midsummer it reached a mean of 88·8 ml./kgm./24 hr. Corresponding 2 p.m. respiratory-rates were 38 ± 11/min. in winter and 154 ± 43/min. in summer. Urine output (8 sheep) in winter was 1·34 ± 0·65 l./24 hr. and in summer 0·73 ± 0·30 l./24 hr. The mean output, in ml./kgm./24 hr., was 35 and 46 in successive winters, and 24 and 15 in successive summers. We have found that a standard heat stimulus of 40° C. releases antidiuretic substances in summer, but not in winter. Water for evaporative cooling by panting is provided in summer by drinking twelve times the winter water intake; and by reduction of urine to half the winter volume. Young sheep, also, stored 28 per cent more extracellular water in summer than in winter.

Sheep standing in the open, between noon and 2 p.m. in summer, were exposed to air temperatures between 36° and 42° C., and radiant insolation of 700 k.cal./m.^{2}/hr. Wool tip temperatures rose to 87° C. (190° F.) and the corresponding skin temperature was 42° C., with rectal temperatures of 40·0–40·5° C. Tip wool heats rapidly in the sun and is cooled by air movement. When the terminal 1 cm. was clipped away reflectance doubled (to 0·36 cal./cm.^{2}/min.) and the clean tip temperature fell by 17–20 deg. C. The dark weathered tip accepts more heat than freshly cut wool; but the skin is insulated effectively, for 4 cm. of wool sustained a gradient of 45° C. between tip and skin. An inverse relation was observed between length of wool and respiratory-rate of sheep in the sun. Two pairs of similar merino wethers, for example, were compared while insolated. Two shorn sheep with 1 cm. of wool had skin temperatures 3 deg. C. hotter than the unshorn carrying 3·5 cm. of wool. Shorn sheep panted at 230 ± 26/min., while unshorn sheep panted at 108 ± 23/min. in an ambient air temperature of 38° C.

The interactions of these heat loads and water reserves were studied by depriving five wethers of water for four days, and three for five days. The 50 kgm. animals were 27 months old. They stood in the summer sun and were allowed full rations of *Astrebla* (Mitchell grass) hay supplemented with grain.

Table 1

	Initial	120 hr. without water	Per cent change
Body weight (kgm.)	50·3	38·5	− 23
SCN space (l.)	13·3	7·3	− 45
Plasma vol. (l.)	3·16	1·74	− 45
Plasma sodium (m.eq./l.)	144·1	157·0	+ 9
Plasma chloride (m.eq./l.)	111·0	142·0	+ 28
Plasma osmotic pressure (Δ° C.)	0·585	0·782	+ 34
Max. urine osmotic pressure (Δ° C.)	4·180	5·940	+ 42

Mean values for body fluid volumes and concentrations induced in three merino wethers by five days without drinking water. Food was supplied. The sheep were exposed to sun in air temperatures reaching 40° C. (104° F.) with relative humidity between 10 and 50 per cent

Rectal temperature reached 41° C., extracellular fluids (Table 1) were reduced by 45 per cent and the plasma osmotic pressure increased by 34 per cent. Plasma protein concentration rose 60 per cent and the hæmatocrit 39 per cent. Plasma sodium rose only 9 per cent, though urinary sodium/potassium fell, so sodium probably entered cells. Each plasma constituent seemed separately adjusted to dehydration.

Urinary water-loss averaged 1,680 ml. in 120 hr. (0·23 ml./min.) and in that time 702 m.equiv. sodium and 486 m.equiv. potassium were excreted. Urine volume fell from 585 ml. to 130 ml./24 hr. by the fifth day. Two sheep had less power of renal concentration after the third day, although urine volume continued to fall. Osmotic pressure of the urine rose to a maximum of 3,190 m.osmols and specific gravity reached 1·069. Less than half the osmolarity of the urine could be accounted for by sodium and potassium salts. As dehydration continued the urine sodium/potassium ratio fell from 1·8 to 1·2. When offered water after five days the sheep drank 7–9 l. at once. The following 24-hr. urine volume did not exceed 250 ml., but the sodium/potassium ratio fell to 0·2. Sodium was thus retained to hold the water ingested. The sheep were apparently unharmed by five days without water. The Schmidt-Nielsens[1] found that kangaroo rats concentrate urine to 5·5 osmols. The rock wallaby *Setonyx*[2] achieves 2·1 osmols. Merinos approach the camel in power of water conservation[3].

In contrast with the day to night change of rectal temperature over 4–7 deg. C. found in the camel, the merino in summer has a fluctuation of only 1·5–2·0 deg. C. The relative stability is achieved by panting. Sheep, accordingly, lose water somewhat faster than the camel. But the merino tolerates a similar water loss to the camel, and survives more extracellular volume reduction than is possible for man. From a mean weight-loss of 11·8 kgm. it was found in the dehydrated merino that 5·2 kgm. could be assigned to tissue wastage and intracellular water loss. These losses approach those survived by camels. Attempts to measure directly intracellular water of merinos by antipyrine failed because of the rapid rate of removal of antipyrine in sheep and the unpredictable occurrence of impossible dilution curves.

Adaptation to high heat loads and dehydration by merinos involves insulation by wool against radiation, production of antidiuretic substances in summer to help concentrate urine to 3 osmols, toleration of reduction of plasma volume to half, and increase of plasma osmotic pressure to 440 m.osmols/l.

We are grateful to the Commonwealth Scientific and Industrial Research Organization Wool Fund for a grant. Mr. G. R. Moule, Mr. R. B. Young and their associates at Toorak gave invaluable help in the field.

EFFECT OF TEMPERATURE UPON THE CROSS-LINKING OF POLYETHYLENE BY HIGH-ENERGY RADIATION

By R. M. BLACK

British Insulated Callender's Cables, Ltd., Research Organization, 38 Wood Lane, London, W.12

RECENT work upon the degradation of polymethyl methacrylate by gamma-radiation[1] has shown that the radiation appears to have a greater effect at a higher temperature and that less energy is therefore required to degrade the polymer at 74° than at 18° C. With poly*iso*butylene, the effect has been studied in greater detail[2] and the experiments carried out leave no doubt as to its validity. From the initial experiments the dependence on temperature would seem to be rather unusual in character; the number of main-chain fractures for a given energy deposition increases approximately proportionally to the absolute temperature.

In view of the possible implications of this phenomenon for the mechanism by which radiation-induced changes are brought about in polymers, the behaviour of a system which exhibits cross-linking rather than degradation has been investigated. Polyethylene is particularly suitable for this purpose as, not only has its behaviour under irradiation been studied in considerable detail by Charlesby and his colleagues[3], but also the irradiated polymer exhibits rubber-like elasticity at temperatures above 120° C. which can readily be measured and is directly related to the degree of cross-linking[4].

A series of polyethylene specimens ('Alkathene' grade 7), cut to the shape of standard 3-in. dumb-bells, were irradiated in a 400-curie cobalt source over a temperature range − 196° to 75° C. The energy deposited in the specimen was estimated by ferrous sulphate dosimetry, taking the value of $G(\text{Fe}^{3+}) = 20$.

Elastic moduli of the irradiated specimens were measured by suspending the specimen in a constant temperature oven at 140° C. and applying weights at regular intervals by means of a cantilever device through the roof of the oven.

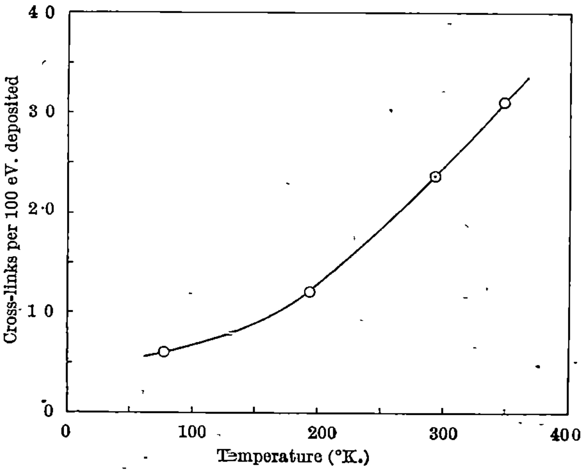

Fig. 1. Effect of temperature upon the cross-linking of polyethylene by gamma radiation

For rubber-like elasticity, the elastic modulus is inversely proportional to the molecular weight between cross-links (M_c), and can be expressed by the relationship :

$$E = \frac{3\rho R_g T}{M_c} \qquad (1)$$

where E is the elastic modulus in dynes/cm.², ρ the density of the polymer ($\sim 0{\cdot}92$), R_g is the gas constant ($8{\cdot}3156 \times 10^7$ in c.g.s. units), and T the absolute temperature at which the measurement is made (413° K). Now, M_c is defined by the expression :

$$M_c = \frac{M_0}{\gamma} \qquad (2)$$

where M_0 is the initial number-average molecular weight of the polymer and γ the cross-linking index or average number of cross-links per molecule produced by unit radiation dose. If q is the fraction of monomers cross-linked by such a dose and the number of cross-links is proportional to the radiation dose, R, received, then in a polymer of initial molecular weight M_0 there will be $M_0/14$ carbon atoms capable of being cross-linked and the molecular weight between cross-links after a radiation dose R will be given by :

$$M_c = \frac{14}{qR} \qquad (3)$$

Substituting this value for M_c in equation (1) gives :

$$E = \frac{3\rho R_g T q R}{14} \qquad (4)$$

It is desirable to express the amount of cross-linking produced by a given radiation dose in terms of the number of cross-links produced by an energy deposition of 100 eV., in agreement with present-day radiation chemistry procedure (G values), whence the G value for cross-linking (G_c) will be given by :

$$G_c = \frac{\text{fraction of carbons cross-linked in 1 gm. polymer}}{\text{energy deposited in 1 gm.}} \times 100$$

$$G_c = \frac{(N/14)q.R \times 100}{R} \quad (N \text{ is Avogadro's number, } 6{\cdot}023 \times 10^{23})$$

If R is initially expressed in eV. per gm. this becomes :

$$G_c = \frac{100Nq}{14} \qquad (5)$$

Substituting this value of q in equation (4) will give the G value in terms of elastic modulus and radiation dose only, whence it can be shown that

$$G_c = 6{\cdot}35 \times 10^{14} E/R \qquad (6)$$

Fig. 1 shows the values calculated in this manner over the range 77°–348° K. It is uncertain whether the curve should pass through the absolute zero.

As with polymers in which degradation processes predominate after exposure to high-energy radiation, the measured values leave no doubt that less energy is required to produce a cross-link as the irradiation temperature is increased. Moreover, the temperature relationship appears to be very similar, as can be seen from the curves of Fig. 2.

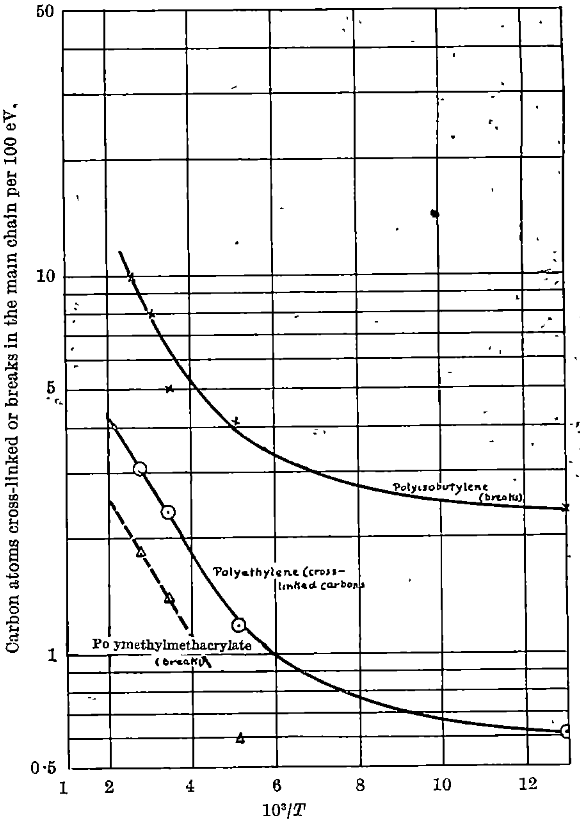

Fig. 2. Effect of irradiation temperature upon cross-linking and chain fracture in vinyl polymers

The mechanism by which cross-linking or degradation takes place must involve at least three stages : excitation or energy absorption, dissociation with ion or radical formation, and interaction of the excited radicals or ions to give stable products, whether carbon–carbon double bonds, cross-links or by disproportionation chain fracture. The amount of energy initially absorbed by the molecules which results in chemical change is very small, as bond-energies in general are of the order of 3–4 eV. and a larger proportion of the energy is either degraded into heat or re-emitted in the form of fluorescence radiation, which may afterwards be re-absorbed to bring about photo-dissociation[5]. This absorption process is generally held to be independent of temperature and it can therefore be concluded that the temperature effect is to be found in either the dissociation or interaction stages of the process. At first sight it might appear that the interaction stage is the critical one, as a plot of log G_c against I/T is approximately linear down to − 80° C. ; but, in view of the similar dependence on temperature of both cross-linking and chain-fracturing reactions, there is a possibility that the dissociation stage may also be involved.

My thanks are due to Dr. L. G. Brazier, director of research and education, British Insulated Callender's Cables, Ltd., for permission to publish this communication, and to Dr. P. Alexander and Dr. A. Charlesby for helpful discussion.

Effects of Ionizing Radiations on Serum Complement and Enzymes

ANIMALS exposed to ionizing radiations almost invariably have a lowered resistance to bacterial infection. The serum complement system which aids lysis of invading bacteria is known to be readily inactivated by radiomimetic substances such as nitrogen mustard[1], and it was considered of interest to examine the effects of X-rays and electrons on this system *in vitro*. It was hoped that an investigation of the effect of various types of radiations on the relatively labile complement system might yield useful information about the biological effects of these radiations. The 15-MeV. linear accelerator at St. Bartholomew's Hospital has been used as the source of X-rays and electrons in all our experiments, and guinea pig serum has been used as a source of complement.

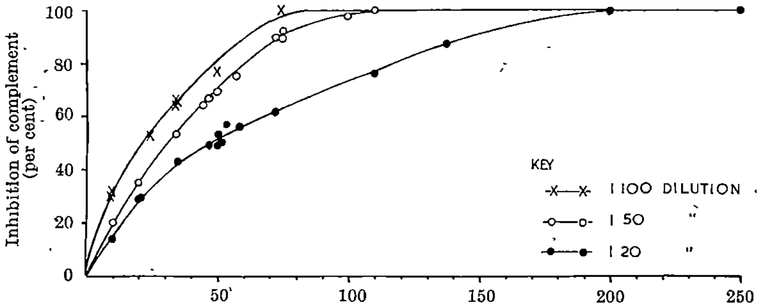

Fig 1

It has been found that doses of X-rays and electrons up to 200,000 rads have little or no detectable effect, if undiluted serum or strong solutions are irradiated; but when dilute solutions are irradiated, the specific hæmolytic activity of serum complement is destroyed. Fig. 1 shows the inhibition produced by irradiation with electrons as a function of dose and concentration of serum. With a very dilute serum (1 : 100 dilution) some inhibition was observed with as little as 500 rads, and it is considered probable that the enhanced destruction of complement in dilute solutions may be a result of the reduction of concentration of protective substances in the serum.

When using electron irradiation, the mean dose-rate was about 12 million rads per min.; but practically the same results were obtained with X-rays at a dose-rate of about 1,000 rads per min., indicating that the effect is independent of dose-rate.

The percentage inhibition is approximately an exponential function of the dose, but there does not appear to be a simple relationship between the amount of destruction and the degree of serum dilution.

In most of these experiments the diluted serum was irradiated in the presence of air; but irradiation of the serum in a Thunberg tube from which the air had been removed and replaced by nitrogen containing 5 per cent carbon dioxide did not produce a significant change in destruction of the complement in 1 : 20 or 1 : 50 dilution of serum, by an X-ray dose of 50,000 rads.

The destructive effect of X-rays on complement can be partially prevented by the addition of cysteine or cysteamine to the diluted serum before irradiation. For example, a dose of 50,000 rads completely destroyed the complement activity of diluted (1 : 50) serum, but the inhibition was reduced to 48 per cent in the presence of $M/500$ cysteine and to 32 per cent in the presence of $M/500$ cysteamine.

The possibility that complement inactivation by radiation was due to the production of anti-complementary substances in the serum during the irradiation has been examined. Irradiated dilute serum was added to normal serum, and subsequent determination of the total complement titre showed that no long-lived inhibitory substance was present in the irradiated serum.

An examination of the enzymic activity of samples of the irradiated and non-irradiated 1 : 20 and 1 : 50 diluted serum used for the complement tests showed that X-ray doses of 20 and 50 kilorads caused no reduction in the activity of the cholinesterase, lipase or alkaline phosphatase present in the serum. The fact that these enzymes are unaffected by the same conditions in which complement is powerfully inactivated emphasizes the marked selectivity in the biological effects of X-rays. This work is being continued by studying the serum complement and enzyme activity-levels in irradiated guinea pigs and other experimental animals.

Since hæmolytic complement is readily inactivated by nitrogen mustard[1], the results presented here provide a further instance of the similarity in biological effects produced by X-rays and the so-called radiomimetic substances (such as the nitrogen mustards).

These investigations form part of a programme of research carried out with the aid of grants provided by the Treasurer and the Board of Governors from the Discretionary Fund of St. Bartholomew's Hospital. One of us (P. J. H.) is also indebted to the Medical Research Council for a studentship.

Absolute Amount of Ribonucleic Acid in Viruses

ON the basis of work with plant virus strains, Knight[1] expressed the view that all strains of virus contain the same quantity of nucleic acid. Recent experiments have shown that there exist a number of animal viruses which contain only ribonucleic acid. If one plots the percentage of ribonucleic acid against the particle weight of viruses containing ribonucleic

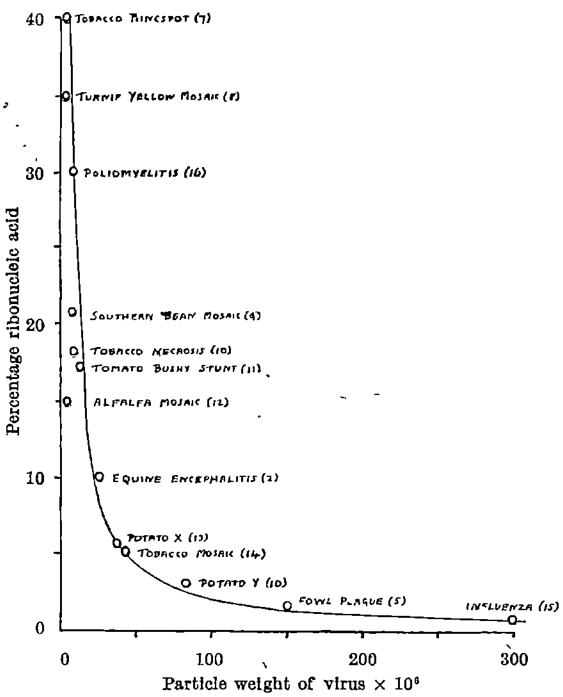

Fig 1. Percentage of ribonucleic acid in relation to particle weight of viruses containing ribonucleic acid

acid, a hyperbola results. Thus in animal viruses also the absolute amount of ribonucleic acid seems to be the same, and coincides with the quantity found in most plant viruses. As the actual equation of the hyperbola is percentage ribonucleic acid × molecular weight of the virus = 2×10^8, the average weight of the ribonucleic acid in a single virus particle amounts roughly to two million times that of a hydrogen atom.

This amount of ribonucleic acid consists of about 6,000 nucleotides. However, this should not be interpreted to be a single macromolecule comparable to some sort of gene. It has been shown in some strains of plant and animal viruses that there are smaller sub-units containing the total ribonucleic acid in smaller portions. Tobacco mosaic virus can be degraded to about 108 sub-units, still containing 5·5 per cent ribonucleic acid. This sub-unit has a particle weight of 360,000 [2]. If this unit contains only one molecule of ribonucleic acid, the molecular weight of the nucleic acid would be 20,000 and it would contain 60 nucleotides. The sub-unit of the influenza virus containing ribonucleic acid is the soluble antigen with a particle weight of 600,000 and a ribonucleic acid content of 5·3 per cent. About 70 such sub-units were found in an elementary body of the virus[3]. In this case the ribonucleic acid would contain 100 nucleotides. There are about 13 sub-units containing ribonucleic acid in fowl plague virus. These have a particle weight of about 1,300,000 and a ribonucleic acid content of 15 per cent[4,5]. The ribonucleic acid contains about 600 nucleotides.

It is probable that one single virus particle is sufficient to infect the host cell[6]. In spite of the different sizes of the elementary bodies and the different numbers of sub-units containing ribonucleic acid, it seems that it is the absolute amount of ribonucleic acid which is concerned with turning the normal metabolism of the host cell into virus production. This amount seems to be the same for viruses ranging from a particle weight of some millions to some hundreds of millions and acting upon a great variety of hosts—plants as well as animals.

Isotopes incorporated in the Nucleic Acids of *Trypanosoma mega*

THE trypanosomes can be cultured in media containing nucleic acids or purines. *Crithidia fasciculata* grows in a synthetic medium with folic acid, guanine or guanosine[1,2]. *Trypanosoma cruzi* has been cultured by Citri and Grossowicz[3] in a defined medium enriched with ribonucleic acid, and its growth is stimulated by guanosine. *T. rhodesiense* seems to need adenine and adenosine as growth factors[4].

In view of these facts, we thought it interesting to try to discover whether trypanosomes could synthesize nucleic purines from simpler precursors such as labelled glycine and formate.

Experiments were made with a trypanosome isolated from the African toad, *Bufo regularis*. This trypanosome is morphologically identical with *Trypanosoma mega*, described by Dutton and Todd, Broden and Rodhain[5]. It has been cultured for more than a year in the medium used successfully by one of us (G. J. B.) for *T. cruzi*. This medium has the following composition: NaCl, 4 gm.; $\text{Na}_3\text{PO}_4 12\text{H}_2\text{O}$, 5 gm.; KCl, 0·4 gm.; glucose, 2 gm.; 'Bacto-tryptose Difco', 15 gm.; 'Oxoid' liver infusion, 1 gm.; hæmin, 20 mgm.; twice-distilled water, 1,000 ml.; *p*H adjusted to 7·8. The solution was sterilized by autoclaving for 10 min. at 10 lb. This medium contains large quantities of free purine bases, mainly hypoxanthine.

The trypanosomes were cultured at 24° C. either in roller tubes or in flat-bottomed flasks. After seven days, the culture was centrifuged, the trypanosomes were washed with buffered saline and suspended in culture medium containing a known quantity of labelled precursor (0·25–0·50 μc./ml.). After a period of incubation of 10–50 min. at 24° C., the trypanosomes were killed by ice-cold 1 per cent trichloracetic acid; they were washed several times with a 1 per cent trichloracetic acid solution of a carrier (adenine, formate or glycine, according to the experiments). The ribonucleic acids and deoxyribonucleic acids were hydrolysed and their components analysed by paper chromatography according to the method previously described by one of us (M. S.)[6]. The specific incorporation of the isotopes was determined in the adenine and in the guanine of both nucleic acids.

Adenine-8^{14}C was rapidly incorporated by *T. mega* for the synthesis of its nucleic acids. Adenine isolated from ribonucleic acid had a specific activity 3–10 times higher than adenine isolated from deoxyribonucleic acid. Adenine was incorporated 4–5 times more rapidly in the adenine-ribotides than in the guanine-ribotides, and about twice as rapidly in the adenine-deoxyribotides as in the guanine-deoxyribotides.

Simpler precursors such as glycine-2^{14}C and formate-^{14}C, even when samples of higher specific activity were used, were not incorporated in the purine bases of trypanosomes, although actively incorporated in their proteins. It seems, therefore, that *Trypanosoma mega* is unable to synthesize the purine nucleus.

The rapid incorporation of free adenine by *T. mega* suggests that the ribonucleic acid contained in the medium of Citri and Grossowicz could be, at least partially, replaced by free bases.

Metabolism of Isolated Liver Cells

Longmuir and ap Rees[1] have recently described a new method for preparing suspensions of isolated rat liver cells. We have been interested for some time in the metabolic properties of such isolated cells, and wish to direct attention to some of their peculiarities not mentioned by these authors.

Four methods are now available for preparing such material: (*a*) simple squeezing or crushing of the liver tissue; (*b*) the method of Anderson[2], in which the cells are loosened by a preliminary perfusion of the organ with a calcium-free solution containing citrate or versene, with subsequent squeezing of the tissue as in (*a*); (*c*) the method of Kaltenbach[3], in which the tissue without previous treatment is pushed through sieves of increasingly fine mesh; and (*d*) the method of Longmuir and ap Rees[1], in which the minced tissue is incubated in a slightly acid medium (*p*H 5–6) and then disrupted by violent agitation. In all four methods a large proportion of the cells is broken, and the remaining whole cells are obtained free from cytoplasm, cytoplasmic particles, nuclei, debris and red blood cells by differential centrifugation. The yield of isolated cells obtained by the different methods varies very widely, that of Anderson giving in our hands a yield incomparably better than any of the others (Table 1); moreover, this method invariably yields suspensions consisting almost exclusively of single cells, whereas those obtained by the other methods we have found to be frequently contaminated with cell clumps.

Table 1. Total Dry Weight of Isolated Rat Liver Cells obtained by Four Different Methods

Method of preparation	No. of exps.	Average yield of cells (mgm. dry wt./rat liver)
1. Simple washing	2	20
2. Method of Anderson (ref. 2)	13	190
3. Method of Kaltenbach (ref. 3)	3	18
4. Method of Longmuir and ap Rees (ref. 1)	3	12

The outstanding characteristic of these isolated cells, by whichever method prepared, is a complete absence of respiration, and no addition to the medium so far tested will restore this capacity (glucose, pyruvate, citrate, cytochrome *c*, adenosine triphosphate, blood serum and a liver extract freed from mitochondria have been added; 2 : 4-dinitrophenol also does not elicit any respiratory activity). Kaltenbach[3] has stated that cells prepared by his method show a respiration not dependent on the addition of succinate but does not indicate its magnitude; this we have not been able to confirm.

Further, the isolated cells have lost their capacity to convert intracellular glycogen to lactic acid. The only metabolic processes associated with catabolism which remain are those of succinoxidase and fumarase. The succinoxidase activity is of similar magnitude in cells prepared by all four methods (Table 2) and is greatly augmented compared with the values found in the original tissue; it is not affected by the addition of cytochrome *c*. In several batches of cells Q_{O_2} values in the range − 140 to − 160 have been observed, and these are higher than can be accounted for by the activity of the isolated mitochondria[4]. It appears, therefore, that the mitochondria *in situ* are more active in this respect than when isolated in hypertonic sucrose solution.

Table 2. Endogenous Respiration and Succinoxidase Activity of Liver Cells, in Slices and in Suspension

Condition of cells	Method of preparation	No of exps.	Q_{O_2} (endogenous)	Q_{O_2} (succ.)
Slices	—	8	−11·1	−26·2
Isolated cells	Crushing	2	−0·3	−68
,,	Anderson (ref. 2)	11	−0·2	−113
,,	Kaltenbach (ref. 3)	2	0	−73
,,	Longmuir and ap Rees (ref. 1)	2	0	−88

Longmuir and ap Rees[1] give a figure of − 18 for the Q_{O_2} of their cells in the presence of succinate. This is about one-sixth of the figure we have obtained, and the discrepancy may perhaps be explained by the following facts. The Q_{O_2}(succ.) of the cells is maximal only at high succinate concentrations (0·025 *M*), and only if the cell concentration in the test mixture exceeds a critical value which is of the order of 1·5 mgm. dry weight/ml. (Table 3). The

Table 3. Relationship between Cell Concentration and Q_{O_2}

Concentration of cells (mgm. dry wt./ml.)	Q_{O_2} (succ.)
0·52	−2
1·03	−70
1·55	−90
2·5	−96
3·6	−107
5·2	−96

succinoxidase activity which is lost on dilution of the cells may be restored by the addition of an extract of liver cells, but not by cytochrome *c*.

We believe the most interesting part of these observations is the complete loss of endogenous metabolism in isolated liver cells, by whatever method they are prepared, and are anxious to discover the nature of the change in the cells which leads to this result. By contrast, it is well known that isolated tumour cells of various ascites tumours are still capable of catabolizing, and at an increased rate compared with the same tumour grown in the solid form.

Salicylate and Carbohydrate Metabolism

WE have observed that when rat diaphragms are incubated aerobically in the medium of Sacks and Sinex[1] with $5 \times 10^{-3}\,M$ salicylate the amounts of creatine phosphate and adenosine triphosphate in the tissue are significantly reduced and the inorganic phosphorus increased (Table 1).

A possible explanation of these results is that salicylate interferes with oxidative phosphorylation processes and inhibits the synthesis of high-energy phosphate bonds. Support for this view is provided by the similarity between the effects of salicylate and 2:4-dinitrophenol, which is known to interfere with oxidative phosphorylation reactions[2]. Both salicylate and dinitrophenol increase the oxygen consumption of whole animals and isolated tissues[3,4] and dinitrophenol also reduces the creatine phosphate and adenosine triphosphate in the rat diaphragm[1,5].

$5 \times 10^{-3}\,M$ salicylate has been observed[6] to decrease the glycogen and increase the lactic acid production and the respiratory quotient of the rat diaphragm, and these changes may be evidence of substrate being broken down to provide energy for increasingly inefficient phosphorylation processes. The decreased glucose uptake also found in the diaphragms in the presence of salicylate is explicable on the same basis if the first step in glucose utilization involves phosphorylation.

The concept that salicylate may prevent the normal synthesis of high-energy phosphate bonds and hence impair the general efficiency of synthetic processes may also provide an explanation of some of the effects of the substance on carbohydrate metabolism in animals. The subcutaneous injection of salicylate, producing plasma salicylate concentrations of the order of $5 \times 10^{-3}\,M$, causes a marked depletion of the blood glucose concentration of the fasted alloxan-diabetic rat[7]. In this animal preparation the blood glucose-level is maintained by synthetic reactions, the increased liver glucose-6-phosphatase activity present[8] producing hyperglycæmia rather than deposition of liver glycogen. The hypoglycæmic effect of salicylate may therefore be due to an impairment of synthetic ability caused by an interference with the formation of high-energy phosphate bonds. Similar considerations may apply to the effect of salicylate in causing a depletion of the liver glycogen in the normal rat[9] although adrenaline release may also be an important factor[10].

Full details of the experiments described above will be published elsewhere.

Elastomucoproteinase and Collagenmucoproteinase, the Mucolytic Enzymes of the Pancreas

THE elastolytic enzyme of human and animal pancreas which we have named elastase[1–4] seemed to be specific for elastic fibre[5], but apparently had no effect on native collagen fibre. Hall, Reed and Tunbridge[6] have shown that elastase preparations have some effect on the mucopolysaccharide of elastin also, and during digestion sulphate and polysaccharide components are split off from elastin. Hall[7] suggests the existence of two enzymes acting on elastin, having evidence that one of these must be regarded as a mucolytic one. Partridge and Davis[8] determined the release of N-terminal residues from elastin by elastase

Table 1. EFFECT OF $5 \times 10^{-3}\,M$ SALICYLATE ON THE INORGANIC PHOSPHORUS, CREATINE PHOSPHATE AND ADENOSINE TRIPHOSPHATE OF THE RAT DIAPHRAGM INCUBATED AEROBICALLY

Mean values ± *S.D.* and ranges are given for the results, which are expressed as mgm. inorganic phosphorus/100 gm. wet weight. The figures in brackets represent the number of experiments

	Inorganic phosphorus			Creatine phosphate			Adenosine triphosphate		
Time (min.)	15 (8)	30 (12)	60 (11)	15 (8)	30 (12)	60 (11)	15 (8)	30 (6)	60 (8)
Control	23·2±3·7 18·1–29·3	25·5±3·7 20·2–31·3	25·7±4·0 19·8–32·1	22·6±3·4 18·4–29·3	19·1±3·6 13·0–24·1	18·4±4·8 10·6–24·1	27·9±4·4 21·7–34·4	20·9±3·8 16·6–27·0	24·3±3·4 18·4–27·5
Salicylate	51·6±3·6 46·9–55·5	41·8±4·2 35·4–47·7	36·4±4·6 30·0–41·4	1·5±2·5 0–7·5	3·5±2·9 0–7·0	3·8±2·0 1·0–6·7	14·3±6·0 3·8–25·2	3·9±2·9 0–7·7	7·6±2·7 5·2–12·2

Statistical comparison between the results of the control and salicylate groups showed that $P < 0{\cdot}001$ at each point and concluded that elastase preparation contains a proteolytic component also.

Our recent experiments have proved that elastase preparation purified to a high degree is still not homogeneous but consists of several protein components. We wish to retain the name 'elastase' for the enzyme which has a proteolytic effect on elastin. So, according to this nomenclature, the elastase is a proteinase. Banga[9] has shown that besides elastase the pancreatic extract contains an enzyme which acts on the mucoprotein of human sera and is different from the mucolytic enzyme acting on elastin. Here we wish to report some new findings which show that pancreatic extracts do contain enzymes acting on the mucoproteins of connective tissues. Two enzymes will be described, which seem to be distinct from each other. One acts on elastomucin and the other splits the mucoprotein from native collagen fibre. The first may be called elastomucoproteinase and the other collagenmucoproteinase.

The polysaccharide of both the mucoproteins of elastin and collagen was determined by the quantitative method of the Molisch reaction worked out by Szára[10] and used by Bagdy and Szára[11] for the examination of the polysaccharide of fibrinogen. With this method 10–100 μgm. sugar can be determined in an exact manner. The reagent 1-naphthol-2-sulphuric acid is soluble in water, and with glucose, galactose and mannose gives the same mauve colour with uniform intensity. Mucoproteins, enzymatically split from elastin and collagen, react with the reagent but give different colours. The polysaccharide of elastomucin turns from mauve to red with increasing concentration, but the mucoprotein which is split off enzymatically from native collagen fibres reacts with orange-yellow colour. These two different colours prove the difference of the polysaccharide components building up elastomucin and the mucoprotein of collagen respectively. The deviation in colour from the known hexoses indicates that the composition of the mucopolysaccharides of elastin and collagen is not homogeneous and contains unknown components also.

The quantity of the mucoproteins of collagen and elastin which split off enzymatically were determined using concentration curves obtained empirically against a blank. Since these curves are straight lines for concentrations between 10 and 100 μgm. and conform to the monosaccharide of adequate quantity, we inferred that we could calculate the plausible value of these mucopolysaccharides.

The substrate for measuring the elastomucase activity was the preparation of lig. nuchae also used by Hall[7] which was freed from collagen by boiling with acetic acid. The elastomucoproteinase splits off the elastomucin from this preparation. 20–25 per cent of this polysaccharide was dialysed against water, from which we concluded that at least a part of the polysaccharide is present as a component of low molecular weight. The *p*H optimum for elastomucase is 7·3–7·4. The *p*H curve could not be determined in an exact manner in alkaline *p*H because the elastomucin is hydrolysed from the elastin at this *p*H without enzyme too. On the other hand, at alkaline *p*H the elastase which is present in small quantity displays its proteolytic activity also.

For studying the activity of collagenmucoproteinase, collagen fibres of rat-tail tendon and of bovine Achilles tendon were used.

The collagenmucoproteinase dissolves a mucoprotein from the native collagen fibres as well as from the collagen fibres treated with alcohol. The quantity of the dissolved mucoid is 5–8 per cent of the native protein. The polysaccharide content of the mucoprotein is between 8 and 12 per cent, from which 20 per cent can be dialysed against water. The *p*H optimum of the enzyme is 7·4. If the enzyme acts on native collagen fibre the dissolved mucoprotein with 1-naphthol-2-sulphuric acid gives an orange-yellow colour but the mucoprotein dissolved from the alcohol-treated collagen reacts with a red colour. The collagenmucoproteinase has no proteolytic action on collagen and does not dissolve it. The collagen treated with collagenmucoproteinase and afterwards heat-contracted can be dissolved entirely with elastase[12], and the collagenolysate obtained in this way contains 0·20–0·25 per cent polysaccharide, which gives with the above reagent a mauve colour. This observation proves our former suggestion[13] that two kinds of mucopolysaccharide exist in the collagen fibre: that which can be dissolved from the native collagen without dissolving the protein, whereas the other is bound firmly to the protein and can be released only when the collagen is digested.

It seems that the system of the elastase complex contains a whole series of enzymes acting on connective tissue fibres and mucoproteins. These enzymes could not be demonstrated in raw pancreatic extract because of the inhibiting effects of the specific enzyme inhibitors. After purifying the extract these enzymes, which chemically resemble one another closely, can be demonstrated by their specific activity.

Alkaline Phosphatase in the Rabbit Mammary Gland

STRONG positive reactions for alkaline phosphatase have been reported in the basket or 'myo-epithelial' cells of the mammary gland of some pregnant and lactating mammals[1,2]. Progressive transfer of this activity from the basket cells to the adjacent capillary endothelium later in pregnancy has also been described[1].

Mammary tissue from pregnant and lactating rabbits, taken 14, 20, 23 and 24 days after mating and 9 and 14 days after parturition, was fixed for 14 hr. in acetone at 4° C., vacuum-embedded in paraffin (m.p. 45° C.) and sectioned at 5 or 15μ. Alkaline phosphatase activity was demonstrated by Gomori's technique[3] or by a modified coupling azo-dye method[4], using the stable diazotates of *o*-dianisidine or

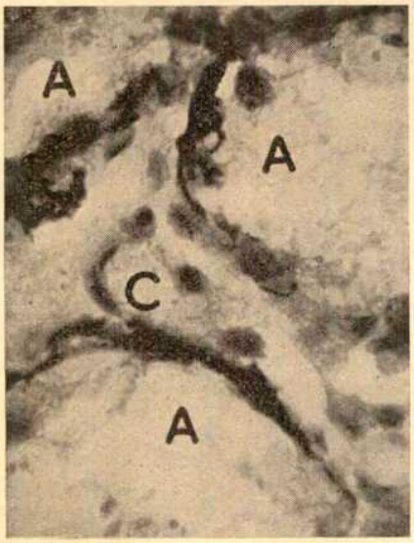

Fig. 1. Mammary tissue from a pregnant rabbit 24 days after mating, incubated with *o*-dianisidine, nuclei coloured by the Feulgen reaction. Parts of three alveoli (*A*) are seen, with the alkaline phosphatase reaction limited to the basket cells. Between them lies a capillary (*C*) the walls of which show a negative reaction. (× 900)

4-chloro-*o*-anisidine, with sodium α-naphthyl phosphate as the substrate. Following incubation some of the sections were treated by the *PAS* technique[4] and in others the nuclei were demonstrated by the Feulgen reaction. These procedures facilitated the accurate localization of the phosphatase reaction without causing any apparent loss of intensity or diffusion of the precipitate compared with untreated sections.

All the samples of tissue except that taken 14 days after mating gave a strong positive reaction after 5 min. incubation with the diazotate; in the latter sample alveolar development was still slight, and the reaction faint. The coloration obtained was sharply limited to the basket cells in all cases, and absent from all nuclei, true alveolar cells, capillary walls and stroma (Fig. 1). Increasing periods of incubation up to 15 min. increased the intensity of coloration but did not affect its location.

The Gomori preparations showed in addition to intense darkening of the basket cells some slight and variable darkening of nuclei, capillary walls and stroma, which became more marked as the incubation time was increased up to 3 hr.; control sections showed no reaction.

It is considered that in the rabbit the alkaline phosphatase of the mammary gland is confined to the basket cells throughout pregnancy and lactation, and that there is no transfer of activity from these cells to the adjacent capillary endothelium in the later part of pregnancy. Rapid embedding in low melting-point paraffin enables alkaline phosphatase activity to be demonstrated with short incubation times, and minimizes diffusion artefacts.

Properties and Composition of the Bile Pigment giving a Direct Diazo Reaction

THE bile pigment, giving the van den Bergh reaction with the diazo reagent in the absence of organic solvents, displays highly polar properties. Conjugated deoxycholic acid has been erroneously supposed to be a component which imparts to this pigment these properties (water-solubility, chloroform-insolubility, electrophoretic mobility, etc.)[1]. This statement was made on the basis of experiments with a preparation from bile containing a large excess of bile salts.

Further experiments[2] concerning the action of enzymes on the directly reacting bile pigment showed the splitting of the bilirubin from the 'direct' pigment under the influence of spleen or bacterial β-glucuronidase and of liver and pancreatic esterases. These enzymic reactions suggest the presence of glucuronic acid in this pigment. The extreme lability toward alkalis is in favour of the ester glucosidic linkage.

In order to prove the presence of glucuronic acid in the direct pigment, the crude preparation from bile (obtained by fractionated precipitation with acetone and rich in this pigment) was purified by reprecipitation with acetone and hydrolysed with ammonia at room temperature. Ammonia was removed *in vacuo* over sulphuric acid and the glucuronic acid was demonstrated by paper chromatography and colour reactions. The bile acids and the ninhydrin-positive material present in the preparation obtained from bile, with the aid of acetone, can be essentially removed. The pigment was precipitated from the solution of this preparation from dog bile by lead acetate and the washed precipitate has the composition corresponding to lead bilirubinyl-*bis*-(β-glucoside uronate)[3].

Billing and Lathe simultaneously came to the same conclusion; but different methods were used in their experiments[4]. Thus, the composition of the directly reacting pigment from bile is now confirmed by independent experiments from both sides.

An Unfavourable Effect of Shaking on Fungal Cellulases

SHAKING in some form or other is often resorted to during the incubation of enzymes with their substrates in order to obtain uniformity of results and a high rate of enzyme activity. In studies with insoluble cellulosic substrates this has been the usual practice among various workers. However, in an investigation of the cellulolytic activities of the culture filtrates of some fungi, preliminary experiments indicated that no advantage was to be gained by shaking, either in uniformity or in rate of enzyme activity, and that shaking might actually be harmful. Some of these experiments are summarized below; fuller details will be published elsewhere.

The culture filtrates were prepared by growing six cellulose-decomposing fungi on Czapek–Dox salt solution with filter paper as carbon source, at 30° C. for 6–9 days; the stale medium, after filtering through fritted glass, was used as the source of enzyme. The substrates were reactive cellulose, prepared by treating cotton linters with phosphoric acid as described by Walseth[1], and sodium carboxymethyl-cellulose, in the form of 'Cellofas *B*', which was dissolved in hot water before use.

Hydrolysis was carried out in 125-ml. duplicate 'Pyrex' conical flasks, each containing 200 mgm. substrate, 2 ml. enzyme and 10 ml. $M/10$ acetate buffer at *p*H 5·0 saturated with the antiseptic pentachlorophenol; the volume was made up to 20 ml. with distilled water. After incubation at 37° C. for 3 hr., 5 ml. of the hydrolysate was withdrawn and titrated for reducing sugar, according to Somogyi's micro-method[2]. The titres were corrected by subtracting the blank titres for substrate alone and enzyme alone.

One set of flasks was incubated in a water-jacketed electrical incubator and the other set clamped to a movable metal frame situated above a thermostatically controlled water-bath; the bottom parts of the flasks were submerged in water and the shaking frame moved with a to-and-fro motion parallel to the water surface across a distance of 0·9 in. with 130 strokes per minute in each direction. In both incubator and water-bath, variation in temperature was well within ± 0·5 deg.

It was found that shaking decreased the hydrolysis of both substrates by all the enzyme solutions (Table 1). Moreover, unshaken flasks gave equally concordant titres. These results were confirmed by repeated experiments in which the time and temperature factors were carefully equalized between incubator and water-bath.

Another experiment indicated that this effect might be partly due to the inactivation of the cellulase enzyme molecule itself by shaking. In this experiment, the six enzyme solutions were first incubated without substrate, with and without shaking, for 3 hr. at 37°; from these, 1 ml. quantities were then reincubated with reactive cellulose as usual. The results given in Table 2 show that enzyme solutions previously shaken were less active than the unshaken ones.

For the sake of comparison, the activities of three other enzymes in a fungal extract prepared from *Aspergillus oryzae* were studied in the shaken and unshaken states. These were invertase, amylase and proteinase, with sucrose, starch and gelatin as substrates. No effect of shaking was observed, except with amylase, which registered a 10 per cent fall in titre in the shaken flasks, after incubation for 3 hr. Equally concordant results were obtained with and without shaking in every case.

Table 1. ENZYME TITRES (ML., $N/200$ THIOSULPHATE) WITH AND WITHOUT SHAKING

Fungus	Sodium carboxymethylcellulose		Reactive cellulose	
	Without shaking	With shaking	Without shaking	With shaking
Curvularia lunata	4·25 4·15	1·55 1·60	1·70 1·70	0·80 0·90

Enzymatic Formation of Hexosamine in Epiphyseal Cartilage Homogenate

CHONDROITIN sulphate, or its protein complex, may be an integral part of the process of calcification[1,2]. Sulphate-containing mucopolysaccharides appear whenever calcification takes place.

According to Neuman *et al.*[3] and Caglioti *et al.*[4] calcium should be bound to the molecule of chondroitin sulphuric acid by one valence of the sulphuric group.

Rubin and Howard[5] found an increase in metachromatic staining in regions where there is active calcification, and attributed this effect to an increase in the concentration of chondroitin sulphate or a change in its degree of polymerization; however, the chondroitin sulphate is modified by the cells during the first stage of calcification. For this reason we have decided to study chondroitin sulphate metabolism in epiphyseal cartilage, beginning with the formation of hexosamine which is a component of chondroitin sulphate.

A preliminary report of this work has already appeared[6].

Work by Leloir and Cardini[7] has shown that hexosamine may be derived from glutamine and hexose-6-phosphate. An enzyme system catalysing this synthesis has been found in *Neurospora crassa*. As significant amounts of hexose-6-phosphate and glutamate are present in the epiphyseal cartilage, a similar enzymatic mechanism was supposed by us to exist in cartilage homogenate.

Epiphyseal cartilage of growing rabbits was used. The tissue was excised at 0° C., and homogenized with a cold solution of 10^{-2} M glutamine and 10^{-2} M glucose-6-phosphate in 0·1 M citrate buffer (*p*H 6·4). Test-tubes were incubated at 30° C. for 3 hr. The enzymatic reaction was blocked by immersion in boiling water for 10 min. and the addition of hydrochloric acid. The final concentration of the acid was $0 \cdot 3\,N$. The hexosamine present in the supernatant liquids before and after incubation was estimated by Schloss's method[8].

These experiments have shown that epiphyseal cartilage homogenates can synthesize very large quantities of hexosamine (*c.* 900γ per gm. of fresh tissue during 3 hr.). This activity is destroyed by immersion of homogenates in boiling water.

Other tissues have been investigated with regard to their ability to synthesize hexosamine : rib cartilage, liver and lung homogenates showed synthesis of very small amounts of hexosamine. Heart, kidney, and spleen homogenates and blood were completely inactive.

We may therefore conclude that a thermolabile enzymatic system, catalysing the synthesis of hexosamine from glutamine and glucose-6-phosphate, is present in epiphyseal cartilage. The enzymatic activity is much greater in this tissue than in others (about ten-fold). For this reason we could consider this enzyme a part of the "local factor(s)" (Sobel[9]) connected with the mechanism of calcification.

Recently a report has been published by Boström *et al.*[10] concerning the influence of glutamine in chondroitin sulphate synthesis in slices of cartilage. Our findings, regarding the formation of hexosamine, and those of Boström *et al.*, regarding the catalytic action of glutamine in chondroitin sulphate synthesis, are essentially in agreement. In fact, hexosamine could constitute an intermediate point in the synthesis of chondroitin sulphate.

Work is being carried out to determine whether, in our experiments, there is an increase in the amount of chondroitin sulphate, utilizing the hexosamine formed by the aforementioned enzyme.

A Rapid Method for estimating Total Protein in Milk

IN 1944, Fraenkel-Conrat and Cooper[1] determined the acid-binding capacities of several proteins by treating the protein with an excess of an anionic dye, orange *G*, at a *p*H of 2·2. The dye and protein react quantitatively to form an insoluble complex which can easily be separated either by centrifuging or filtering. (Ordinary filter paper binds a small amount of dye which must be accounted for to obtain accurate results.) From the concentration of unbound dye (measured colorimetrically), the binding capacity can be calculated. Using this method in principle in an investigation designed to determine the acid-binding capacities of several protein fractions derived from wheat flour, I[2] noted an unexpected uniformity in the binding capacity of mixtures of the two major fractions as obtained from each of several varieties of wheat. These two individual protein fractions have binding capacities differing by a factor of nearly two.

The foregoing observation prompted a study of the binding capacities in whole wheat and wheat flour which led to the conclusion that when the total proteins of either of these products are taken collectively, these proteins can be characterized by a single binding capacity value. Although starch and bran of wheat also bind some dye, the total protein in whole wheat and wheat flour can be conveniently measured by this technique. (A detailed account of this work has recently been published[3]. Application has been made for a public patent.)

An extension of this general technique to the determination of total protein in milk products has been made. The assumption that the total protein in milk also has a common binding capacity is substantiated by the results of tests on more than one hundred samples of milk.

Samples of fresh whole milk and spray-dried milk were obtained from the dairy herd at the State College of Washington through the courtesy of the Department of Dairy Science. Two series of measurements were made. In the first, 1·5 ml. aliquots of fresh milk were mixed with 25·0 ml. of buffered orange *G* dye. The concentration of added dye was 1 gm./l. After being shaken for 5 min., the mixture was centrifuged. The concentration of unbound dye in the clear supernatant was measured in a special absorption cell of short light-path (a note describing this cell has been submitted to *Analytical Chemistry* for publication) using a 470-mμ filter in an Evelyn photoelectric colorimeter. Galvanometer readings were estimated to the nearest 0·1 per cent transmission.

Results of tests on seventy-three samples of liquid whole milk from Holstein, Jersey and Guernsey breeds of dairy cows are presented in Fig. 1. The protein values (N × 6·38) were determined by a standard macro-Kjeldahl procedure in routine analyses by the Dairy Science Department.

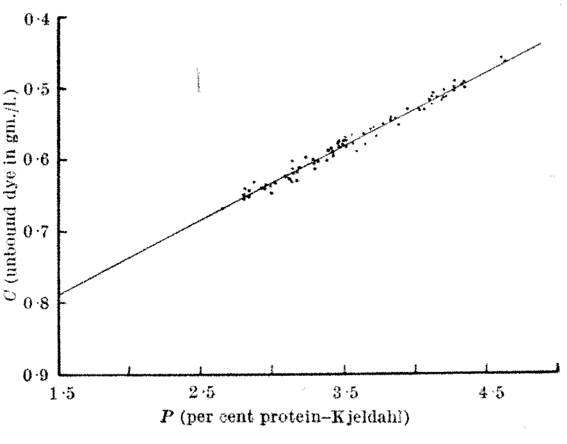

Fig. 1. Relationship between protein content of liquid whole milk and the concentration of unbound dye at equilibrium. Standard error of estimate is 0·07 per cent protein

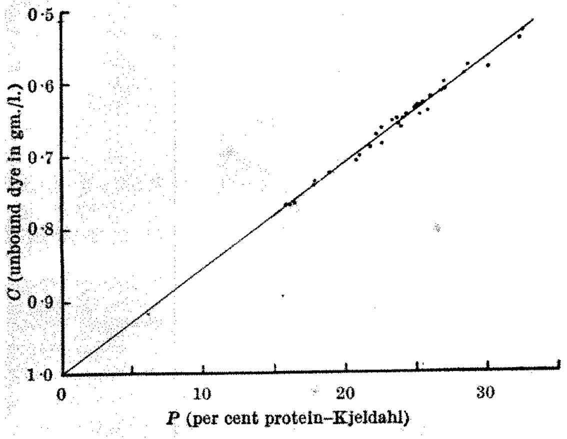

Fig. 2. Relationship between protein content of spray-dried milk and the concentration of unbound dye at equilibrium. Standard error of estimate is 0·42 per cent protein

A second series of measurements was made on thirty-four samples of spray-dried milk. The butter-fat content was altered in some of these samples before spray drying. Except for the size of sample (200 mgm.) and the time of shaking (30 min.), the procedure was unaltered. The ratio of protein to dye was adjusted in each series so that the concentration of unbound dye did not drop appreciably below 0·5 gm./l. Quantitative binding is not obtained if the concentration of dye becomes too dilute. The results are shown in Fig. 2.

Evidently the only constituents binding the dye are the milk proteins, since a line drawn through the experimental points passes very near the origin. In Fig. 1 the origin is different from that in Fig. 2 because of the diluting effect of the added liquid sample (see equation 3 below). A general equation expressing the protein content can be written as follows :

$$P = \frac{100\,[VC_0 - (V + v)\,C]}{kEvd} \qquad (1)$$

where P is the percentage protein, V is the ml. of stock dye solution added, v is the ml. of milk added, C_0 is the concentration of stock dye in gm./l., C is the concentration of unbound dye at equilibrium, k is the equivalent weight of the dye (226 gm.), E is the milliequivalents of dye bound per gram of milk protein, and d is the density of the milk sample.

In the case where the sample is solid, ($v \times d$) in the denominator is replaced by W (the weight of the sample in gm.) and the value of v in the numerator s zero. We then have the equation :

$$P = \frac{100\,V\,(C_0 - C)}{kEW} \qquad (2)$$

When equation (1) is solved for C, we get :

$$C = \frac{VC_0}{(V + v)} - \frac{kvdE}{100\,(V + v)}\,P \qquad (3)$$

This is the equation of a straight line, and as plotted n Figs. 1 and 2, C is the ordinate, P the abscissa, $VC_0/(V + v)$ the intercept, and the coefficient of P s the slope.

Treatment of the results by the method of least quares gave slope values of 0·1043 and 0·01455, espectively, for the data in Figs. 1 and 2. From these lopes, the respective values of E were computed. For liquid whole milk E is 0·792 and for spray-dried milk E has a value of 0·805. The small difference can probably be attributed to denaturation occurring during the processing of spray-dried milk. These values are close to those reported in the literature[4] for casein.

Fractionation of Human Urinary Gonadotrophins

Follicle-stimulating and interstitial cell-stimulating hormones can be extracted from animal pituitary glands; but there is little evidence that two such substances can be separated from human urine. Walter[1] suggests that separation is possible, and recent evidence[2] is claimed to show that the levels of the two hormones in human urine vary independently. This evidence was obtained by using two assays simultaneously: one assay is believed to measure the combined effect of both hormones and the other to measure the follicle-stimulating hormone alone[3]. The two assays have now been used for investigating the fractionation of human urinary gonadotrophins.

Three crude extracts were made from pooled human urine by adsorption on kaolin. The urine was from normal and abnormal subjects belonging to the categories shown in Table 1. No subjects were pregnant, and pregnancy would not have been overlooked as they underwent detailed and prolonged observation. The crude extracts were fractionated by the method of Butt and Crooke[4] and fraction B was assayed in terms of fraction A by both methods.

The results (Table 1) show that comparison of the same fractions by the different assays gave significantly different estimates of relative potency in two cases. All assays were of at least four-point design and there was close parallelism between dose-response lines. The results therefore show that human urinary gonadotrophin can provide fractions with different biological activities.

The probable reason for this biological difference is a separation of the gonadotrophins, but the influence of other hormones must be excluded. It is unlikely that prolactin interferes in these assays; but œstrogen can do so[3]. Both fractions from the young adult women were therefore tested for œstrogen by the method of Butt and Kinnear[5]. The dose given

Table 1

Subjects	Fraction B as percentage of fraction A (95 per cent fiducial limits)	
	Total gonadotrophin assay	Follicle-stimulating hormone assay
Postmenopausal women	21 (11–35)	19 (9–50)
Young adult women	47 (29–66)	20 (15–29)
Men	102 (69–175)	44 (39–50)

to each spayed mouse represented ten times the greatest dose used in the gonadotrophin assays. No œstrogenic effect was detected. There was insufficient material from the men for this test, but in one case at least interference from œstrogen was shown to be unlikely.

The different biological activities of the fractions are therefore considered to demonstrate a partial separation of follicle-stimulating and interstitial cell-stimulating hormones.

This investigation was supported by grants from the Endowment Fund of the United Birmingham Hospitals Medical Research Committee.

Restoration of Sodium-deficient Frog Nerve Fibres by an Isotonic Solution of Guanidinium Chloride

It has been known for some time that certain quaternary ammonium ions are able to restore the ability to conduct impulses to the small myelinated and unmyelinated fibres (*B* and *C* fibres) of frog nerve that has become inexcitable in a sodium-free medium. Quaternary ammonium ions do not restore the excitability of the large myelinated fibres (*A* fibres)[1].

It has been found that the guanidinium ion, which also has a tetracovalent nitrogen atom[2], restores to sodium-deficient *A* fibres the ability to conduct impulses, while it fails to restore the excitability of *B* and *C* fibres.

In order to avoid the question as to whether or not the epineurium is an effective diffusion barrier, the experiments have been performed with the spinal roots or with the sciatic nerve after removal of the epineurium. Large bull-frogs have been used throughout. All solutions were $0{\cdot}11\,N$ and were prepared by dissolving the hydrochloride of the substance in redistilled water in 'Pyrex glass' containers. (Years ago, several samples of a commercial preparation of 10 per cent aqueous solution of tetraethyl-ammonium hydroxide, which was marketed by a reputable firm in containers of soft glass, were found in this laboratory to contain sodium ions at the concentration $8\text{–}10 \times 10^{-3}\,N$.) A few drops of sodium-free $0{\cdot}006\,M$ diethanol-dimethyl-ammonium phosphates buffer were added, which usually brought the *p*H of the solution to 7·2–7·3. When not, the *p*H of the solution was adjusted to 7·2–7·4 with diethanol-dimethyl-ammonium hydroxide. Analyses with a flame photometer have shown that the concentration of sodium ions in the test solutions was below $10^{-5}\,N$. (Frog nerve fibres become inexcitable in a solution containing sodium ions at the concentration $3 \times 10^{-3}\,N$ practically as fast as in a sodium-free medium.)

The motor root becomes inexcitable in an inert sodium-free medium ($0{\cdot}11\,N$ diethanol-dimethyl-ammonium or choline chloride) in 16–25 min. Judging by the height of the restored spike, guanidinium chloride restores the ability to conduct impulses to approximately 80–90 per cent of the *A* fibres. The sensory root becomes inexcitable in 12–20 min. Guanidinium ions restore approximately 70–80 per cent of the *A* fibres. In both instances the restoring action begins instantaneously and becomes maximal in less than 3 min. The desheathed sciatic nerve becomes inexcitable in 2–4 min. and the guanidinium ions restore approximately 60–80 per cent of the *A* fibres. The restoring action begins instantaneously and becomes maximal in less than 5 min. In all cases the spike duration, the speed of conduction and the relatively refractory period of the restored fibres were found to be practically normal.

The effects of several substituted guanidines—methyl, N,N-dimethyl, *n*-amyl and N,N′,N″-triethyl—have been investigated. (Guanidine hydrochloride, methyl guanidine sulphate, N,N-dimethyl guanidine sulphate and arginine hydrochloride were purchased from Distillation Products Industries, Division of Eastman Kodak Company. *n*-Amyl guanidine sulphate was synthesized by the method used by H. King and I. M. Tonkin[3] for the synthesis of *n*-butyl guanidine sulphate. N,N′,N″-Triethyl guanidine was prepared according to A. W. Hoffmann[4].) Although all the N-substituted guanidines are as strong bases as guanidine itself[5], the substituted guanidines do not restore the excitability of any sodium-deficient nerve fibre. Even more, a $0{\cdot}11\,N$ solution of an N-substituted guanidine renders the nerve fibres inexcitable faster than an inert sodium-free solution, and markedly delays and reduces the restoring ability of guanidine and of sodium ions. To be more specific, after the $0{\cdot}11\,N$ solution of a substituted guanidine has been allowed to act upon the nerve for a few minutes, guanidine is able to restore the excitability of only a discrete number of *A* fibres and only after repeated renewal of the guanidine solution. After the action of $0{\cdot}11\,N$ *n*-amyl guanidine hydrochloride, even sodium ions can restore the excitability of only a fraction of the *A* fibres, and only after long, repeated washing of the nerve with Ringer's solution.

This effect of N-substituted guanidines develops without appreciable depolarization of the nerve fibres, which suggests that it is referable to competitive inhibition of chemical processes in the nerve membrane. As a matter of fact, *n*-amyl guanidine readily blocks conduction of impulses in the presence of sodium. Mixtures were made of a $0{\cdot}11\,N$ solution of *n*-amyl guanidine hydrochloride and of a $0{\cdot}11\,N$ solution of sodium chloride in the proportions 15–85, 25–75 and 40–60 parts. The first solution caused block of conduction in a small number of *A* fibres; the second blocked about half the *A* fibres after having caused a marked reduction in the speed of conduction of all, and the third blocked all the *A* fibres in 12–15 min. In all cases recovery after washing with Ringer's solution was prompt and complete.

Although arginine and *n*-amyl guanidine have the same number of carbon atoms, arginine hydrochloride yields a practically inert sodium-free medium. It causes total inexcitability of the nerve in the usual 2–4 min., and affects the restoring actions of guanidine and of sodium ions, if at all, only slightly.

The facts presented in this communication suggest the thought that in the nerve membrane the N-substituted guanidines do not compete directly with sodium ions, but rather with some guanidine-like nitrogen compound.

In regard to the specificity of the various nitrogen compounds that have restoring effects, the following facts should be mentioned. The excitability of sodium-deficient frog muscle is not restored by either quaternary ammonium ions[6] or by guanidinium ions[7]. The excitability of crustacean muscle is maintained in sodium-free solutions of quaternary ammonium ions that are inert for frog nerve[8]. The excitability of the plant cell *Nitella*, that has become inexcitable in distilled water, is restored by ammonia, ammonium ions, guanidinium ions and a number of other compounds[9]. Ammonium ions do not restore frog nerve fibres[10] or muscle fibres[11].

Electrical Activity of the Intrafusal Muscle Fibres

The efferent regulation of sensory discharges in muscle proprioceptors is accomplished by activation of the intrafusal fibres through their motor nerve supply. Contraction of these fibres would produce stretch-deformation of the sensory nerve endings and thereby an increase in the frequency of afferent discharges. In the frog it is achieved mainly by activation of the large-diameter motor axons[1] while in the cat it is elicited only when the small nerve fibres are stimulated[2]. Although the bulk of experimental evidence is quite convincing, it still remains largely indirect because direct observations on intrafusal fibre activity are few.

Some developments in recent years have helped considerably in understanding how the muscular portion of a stretch receptor is capable of modulating the frequency of sensory discharges. Alexandrowicz[3] discovered some special organs in the abdomen of the lobster (*Homarus vulgaris*) which were identified as stretch receptors by Wiersma, Furshpan and Florey[4]. It is possible to study them in complete isolation and under direct microscopic observation. This unique advantage enabled Kuffler[5] and Eyzaguirre and Kuffler[6] to demonstrate that they possess motor nerve fibres which activate either a 'fast', twitch-like bundle or a 'slow' receptor muscle.

The present study was designed to obtain some direct evidence on the behaviour of intrafusal muscle fibres in amphibians. The preparation employed was the muscle extensor longus dig. IV of the Chilean toad (*Callyptocephalus gayi*). The muscle was dissected free and placed in a 'Lucite' dish. It was immersed in Ringer solution covered by a layer of mineral oil. The nerve was lifted into the oil for stimulation and recording with 50μ platinum–iridium electrodes. This thin muscle made a flat and transparent preparation in which details could be easily detected using a combination of dark-field illumination and polarized light. Usually the muscle or the nerve was cut down until a single sensory unit remained discharging. Once the preparation was properly set up, *d*-tubocurarine hydrochloride was added to the bath in concentrations of 1–2 μmol./l. This procedure was employed in order to block extrafusal contractions because it is known that the intrafusal junctions are more resistant to curare than the extrafusal ones[1]. After 30–50 min., complete neuromuscular block was achieved; but the spindles could be seen contracting apparently unimpaired. Thus the intrafusal fibres were impaled with microelectrodes filled with 3 *M* potassium chloride and having a d.c. resistance of 10–60 megohms. The external diameter of the tip was about 0·5μ measured with a water immersion objective and an over-all magnification of × 900.

Isolation of the spindle was attempted as the most direct approach; but this procedure inevitably caused destruction of the motor nerve supply to the intrafusal bundles. Therefore these bundles were identified in the following way: (1) Once a critical level of curarization was reached, one or two very tiny filaments remained contracting. Usually it was difficult to see them unless magnifications of × 40–63 were used. The contraction of these filaments was not strictly isometric even when the muscle tendons were firmly gripped by forceps. (2) An increase in the frequency of sensory discharges was observed if, and only if, this filament contracted. (3) Destruction of the muscle filament by a sharp needle, operated by a micromanipulator, always produced disappearance of the contractions and cessation of frequency changes in spite of strong shocks given to the nerve. (4) An excessive dose of curare produced a similar effect. (5) The zone where the contracting filament appeared was marked and histological sections were made. A spindle was invariably found in such a place (Fig. 1). It is concluded, therefore, that this particular muscle filament is a neuromuscular spindle and that the contracting fibres form part of an intrafusal bundle.

Impalement of the intrafusal fibres was usually very difficult due to their small size (around 10μ) and because in most preparations the spindles were deeply embedded in the muscle mass. Success was achieved when these structures were located near the surface. In one experiment several successful penetrations were possible and resting membrane potentials of 61·3–88·6 mV. measured. A single shock

This bundle had 70 fibres. Circle, spindle with four intrafusal fibres where intracellular recordings were made; arrow, cross-section of thick myelinated, presumably sensory, axon. (× 500)

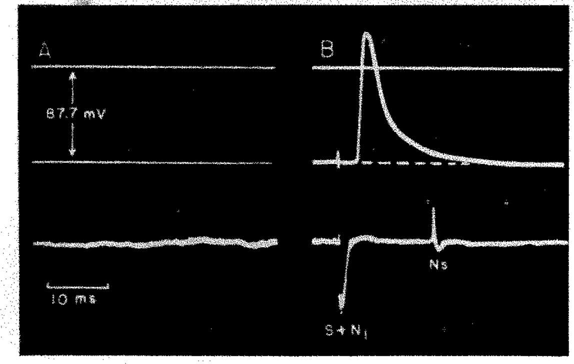

Fig. 2. Electrical activity of neuromuscular spindle. Extrafusal junctions blocked by curare. A single sensory unit was left intact. Upper records in *A* and *B*, intracellular lead from a single intrafusal muscle fibre. Lower records, extracellular electrodes from the nerve. Simultaneous intra- and extra-cellular records.

A, Preparation at rest and under light tension. Resting membrane potential 87·7 mV. Lower record shows no baseline discharge. *B*, After a single nerve shock an action potential of 119·3 mV. is recorded from an intrafusal fibre. Lower record shows artefact plus nerve action potential ($S + N_1$) followed by one sensory discharge (N_s) 15·6 m.sec. after the shock

to the nerve produced action potentials of 84–119·3 mV. and always presenting a positive overshoot of 12·5–31·6 mV. at 21° C. The presence of this spike was always concomitant with an increase in the frequency of sensory discharges (Fig. 2). The characteristics of the action potential indicate that the intrafusal bundles are formed by twitch fibres, innervated by large-diameter motor axons. Nevertheless, the presence of some slow muscle fibres, innervated by the small-nerve motor system, has not been excluded.

Occurrence of Leuco-anthocyanin in Pears

The anthocyanin pigments of plants may occur in two possible colourless forms, as the pseudo-base and as leuco-anthocyanins[1,2]. In both cases conversion to the corresponding anthocyanin occurs on acidification, but is slower in the latter case. Although leuco-anthocyanins have been isolated only from cacao beans[3] and Australian heartwood of *Acacia melanoxylon*[4] their occurrence is implied on the basis of the vanillin test and chromatographic identification of anthocyanins[2,5]. The occurrence of leuco-anthocyanins in pears (*Pyrus communis*) was suggested by Joslyn[6] to explain the reddening that occurs in tinned pears stacked before they are completely cooled, and by Bate-Smith[1] to explain the reddening of stewed pears. Kiesser *et al.*[7] reported the occurrence of leuco-anthocyanins in perry pears on the basis of chemical and chromatographic examination of the insoluble matter causing haze and turbidity and depositing as a sediment in perry. The red pigment obtained by treatment of the sediment with warm dilute acid was found to contain small quantities of phloroglucinol, protocatechuic acid, catechol and cyanidin but was composed chiefly of complex leuco-anthocyanins related to cyanidin. We have recently examined Bartlett pears for the occurrence of leuco-anthocyanins and found evidence for the presence of the leuco-anthocyanin related to cyanidin.

Halved ripe California Bartlett pears tested with vanillin reagent[5] gave a strong positive test for leuco-anthocyanin in the core tissue surrounding the seeds and particularly strong reaction in the seeds. The tissue surrounding the seed receptacle gave a less intense and more diffuse reaction. For this reason, the core tissue was separated, ground and extracted first with boiling water, then with absolute methanol. The residue was then extracted with methanol containing 1 per cent hydrochloric acid. This extract, strongly positive to the vanillin test, was brought to 5–10 per cent hydrochloric acid and heated for 5–10 min. The red pigment so obtained was identified by paper chromatography with several solvent systems. The R_F values obtained with butanol–acetic acid–water, butanol–2 *N* hydrochloric acid and acetic acid–hydrochloric acid–water respectively were: 0·24, 0·47; 0·69; 0·49; respectively. The R_F values reported for cyanidin in these solvents are: 0·24; 0·69; 0·50. Robinson's ferric chloride test was applied to extracts, in *iso*-amyl alcohol containing 1 per cent hydrochloric acid, of pear core tissue, after conversion to anthocyanidin by boiling with added acid. On addition of water, sodium acetate and a small amount of ferric chloride and shaking, the organic solvent layer turned blue just as cyanidin does. The anthocyanidin obtained from pear core and pear seed was stable to oxidation, as is cyanidin. The only anthocyanidin obtained from pear tissue thus is similar in R_F value and other properties to cyanidin.

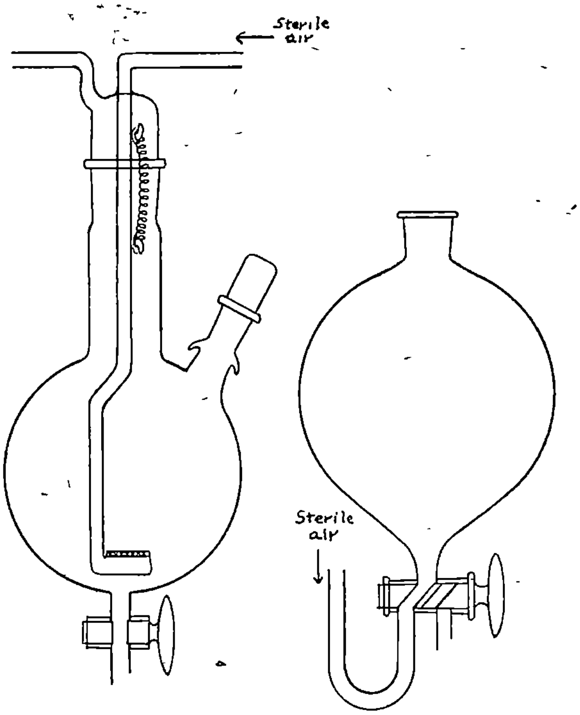
Apparatus for Aeration and Sampling of Bacteria during Growth and Metabolic Studies

The need frequently arises for the sampling of bacterial cultures during aerated growth, or of non-proliferating bacterial suspensions in the course of metabolic studies under aerated conditions. Methods requiring the use of a pipette for the withdrawal of samples are somewhat unsatisfactory because the aeration arrangements, usually capillary tubing or tubing carrying a sintered glass distributor disk, are



(A) (B)

Fig. 1

disturbed when the pipette is introduced into the neck of the flask or tube. The present apparatus were designed to permit aeration and sampling of cultures with the minimum of operations.

Type 1. This apparatus is illustrated in Fig. 1*A*. A 1-litre round-bottom flask with *B*40 neck carries a special glass head with inlet and outlet arms. The inlet tube, which extends almost to the bottom of the flask, bears a sintered glass distributor disk of 20 mm. diameter and porosity No. 1. The head is held in position by two spring clips. At the bottom of the flask is fitted a wide-bore drain stopcock with a stem $\frac{1}{2}$ in. long which permits samples to be withdrawn as required. The combined effect of short stem and wide-bore is to prevent liquid from being retained in the stem. Additionally, the flask has a *B*19 socket set at an angle to the neck ; this is used as an inoculation port or for the addition of substrates. The stopper may be replaced by a tube bent at an angle, so that it forms a side-arm similar to that of a Warburg manometer flask. Simply by rotating this tube in its socket the contents are discharged into the culture flask.

The apparatus is autoclaved in an assembled condition. A small folded strip of Kraft paper is inserted between the ground-glass joints to prevent possible seizure during the process. These joints are then covered over with Kraft paper. After sterilization, the strips of paper are removed with sterile forceps and the joints are then properly seated. The stopcock is lightly treated with silicone grease.

Type 2. With an organism that grows in clumps in liquid media, such as *Sarcina lutea*, even when using vigorous aeration in an apparatus of type 1, there was a tendency for cells to sediment and collect in the stopcock outlet below the glass disk distributor when growth extended over periods of 18–24 hr. To eliminate this difficulty the apparatus shown in Fig. 1*B* was devised. It consists of a 1-litre capacity pear-shaped dropping funnel with *B*24 neck. At the base is fitted a three-way double oblique bore stopcock with one vertical outlet $\frac{1}{2}$ in. long and the other U-shaped. The latter tube is used as the inlet for the sterile air stream which, entering from the base of the funnel, ensures thorough agitation of the medium. By turning the stopcock the air supply is momentarily cut off, a sample withdrawn through the vertical outlet, and aeration then resumed. The mouth of the funnel is closed by a cotton-wool plug. Where a compressed-air supply is not available, the requirements of this apparatus may be met by a small aquarium air pump.

If the air supply is replaced by nitrogen, both pieces of apparatus may be used for anaerobic studies where sedimentation is to be avoided. We have found type 1 to be very useful for organisms such as *Escherichia coli* and *Aerobacter aerogenes* while, as mentioned, type 2 was designed for use in our studies with *Sarcina lutea*.

The pieces of apparatus were made for us by Messrs. Quickfit and Quartz, Ltd., Stone, Staffordshire.

We are indebted to Mr. D. R. S. Cameron for his help and to the Medical Research Council for a grant-in-aid.

Relation between the Optical and Thermodynamic Properties of Saturated Paraffinic Hydrocarbons

The optical properties of hydrocarbons, such as the refractive index and the magneto-optical rotating power, are controlled by absorption frequencies in the far ultra-violet region of the spectrum. These frequencies are due to electronic excitation of the molecules, and since the electrons involved are the outer, that is, the valency, electrons it is reasonable to anticipate a correlation between these electronic transitions and the strength of the valency bonds, that is, the thermodynamic properties of the compounds.

The ratio p/γ, where p is the number of dispersion electrons per molecule effective in optical refraction and γ is the magnetic anomaly, may be calculated from a knowledge of the refractive index (n), the magneto-optical rotating power (V) and the density (d) by the equation[1]

$$\frac{p}{\gamma} = \frac{\pi}{2\lambda^2 eA} \cdot \frac{M}{d} \cdot \frac{(n^2-1)^2}{nV}$$

where λ is the wave-length of the light used, e is the electronic charge and A is the Avogadro number. This equation is valid provided the frequency of the light concerned is far from the frequency of the absorption band, and provided the optical dispersion can be regarded as being controlled by a single absorption frequency. Thus the expression is applicable to most saturated hydrocarbons when sodium D light is used. Darwin and Watson[2] have shown that for most hydrocarbons, γ is approximately 0·60 for the sodium D line. On this basis, values of p have been calculated for forty-two liquid paraffin hydrocarbons in the range C_5 to C_{20}, using values for $n_D{}^{20}$, $V_D{}^{20}$ and d^{20} from the literature[3,4].

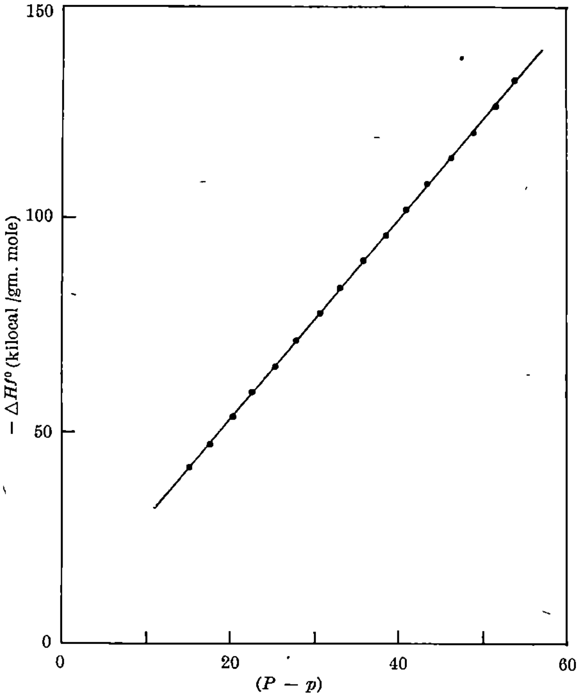

Fig. 1. Relation between standard heat of formation (ΔH_f^0) and number of inactive valency electrons ($P - p$) for *n*-paraffins

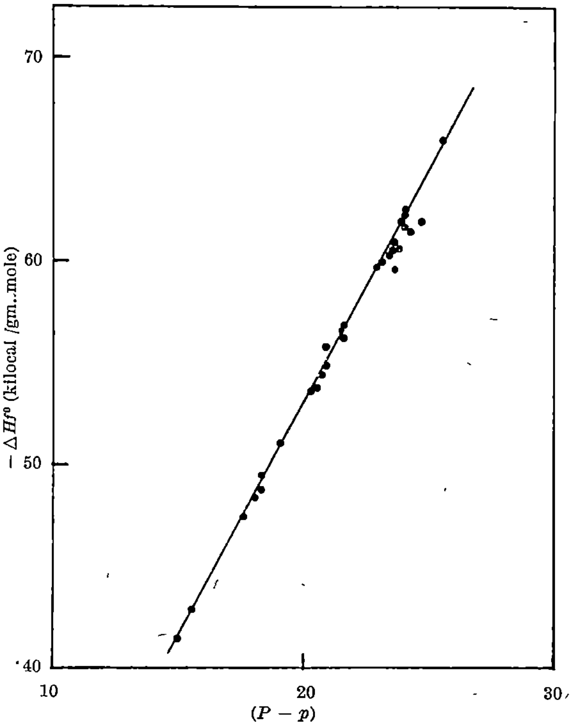

Fig. 2 Relation between standard heat of formation (ΔH_f^0) and number of inactive valency electrons ($P - p$) for pentane, hexane, heptane and octane isomers, and *n*-nonane

Figs. 1 and 2 show that the value of $(P - p)$, where P is the number of valency electrons per molecule, is a linear function of the standard heat of formation of the liquid (ΔH_f^0). The values of ΔH_f^0 used are those listed at 25° C.[5], since it is considered that the small error introduced through the use of the two different temperatures is relative only and does not seriously change the correlation. Deviations from the linear relationships are within the estimated experimental error of the measurements except for three octane isomers. While the linear relation for the *n*-paraffins (Fig. 1) could result from a combination of separate linear relations of ΔH_f^0 and $(P - p)$ with molecular weight, the correlation for the isomers (Fig. 2) suggests that the relation is of a more fundamental character.

Examination of Honey in Australian Honey-ants

The honey-ant (*Melophorus inflatus*) is found in many parts of central Australia, where it is highly regarded by the aborigines as an article of food[1,2]. The honey-bearing ants seem to be modified workers which are fed with nectar or honey by ordinary workers until their distended abdomens approach ⅜ in. in diameter[1]. "In eating them the native seizes each with the fingers by the forepart of the body and, after blowing off the dust, places the distended abdomen of the insect in the mouth and bites it off, letting the slightly acid honey flow over the tongue with evident satisfaction. The abdomen is swallowed while the remainder of the body is discarded"[3]. Colonies of these ants are generally found in rather arid country often near mulga trees. Little seems to be known of their habits, or of the origin of the honey, which is apparently stored against a barren season[4]. As a contribution to this problem, we have now examined the carbohydrate constituents of this honey.

Using a 5 per cent solution of the honey and 1 per cent solutions of glucose and fructose as controls, paper chromatographs were run in pyridine/water/ethyl acetate. and acetic acid/water/ethyl acetate. The application of aniline picrate to the chromatograms developed by both solvent systems gave a prominent spot corresponding to glucose and a less prominent spot corresponding to fructose. The presence of the latter was also confirmed by spraying the paper with urea oxalate. A very faint spot probably corresponding to a disaccharide (but not sucrose) was observed when a 25 per cent solution of the honey was spotted on the paper, which was then developed for fifty-five hours.

An estimation of the reducing sugars by the Lane and Eynon method gave 59 per cent. This result, together with the optical rotation, was used (Mathews formula) for determining the fructose : glucose ratio[5]. This was found to be 0·67. In bee-honey, fructose generally predominates, and this ratio averages 1·20; but wide variations are found, depending on the source of the honey. According to Wetherill[6], the Mexican honey-ant produces honey consisting of an almost pure solution of fructose, but the evidence presented is inconclusive.

We wish to thank Mr. M. J. Barrett, of the Department of Dentistry, who kindly collected some of these honey-ants at the Yuendumu Native Settlement, about 190 miles north-west of Alice Springs.

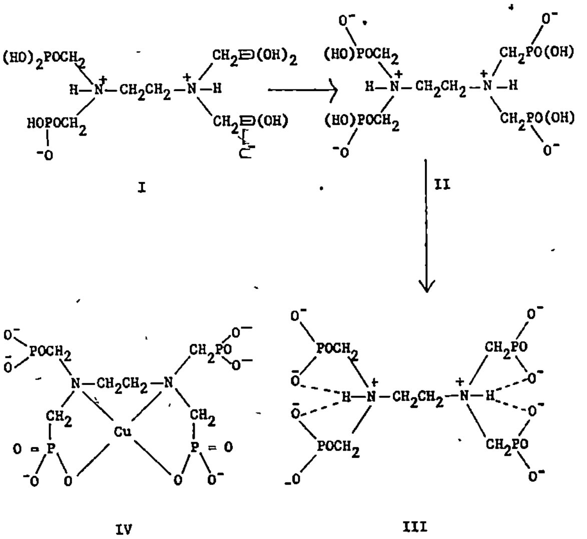
Ethylene-diamine-tetra(methylene-phosphonic) Acid

SINCE the publication by Schwarzenbach *et al.*[1] of the relatively high degree of calcium binding by N-methylene-phosphonic-imino-diacetic acid, it seems that the phosphonate group may be quite as effective as the carboxylate group in chelating agents. An attempt to prepare ethylene-diamine-tetra-methylene-phosphonic acid (EDPA) was therefore indicated because of its similarity to ethylene-diamine-tetra-acetic acid (EDTA). Although the preparation of this and similar compounds has been reported by Bersworth[2], the present communication gives quantitative information of the affinity of the ethylene-diamine-tetra-methylene-phosphonic acid anion for hydrogen ions and metal ions.

The procedure employed in the synthesis of ethylene-diamine-tetra-methylene-phosphonic acid was similar to the methods used by Schwarzenbach *et al.*[1] and Bersworth[2]. Ethylene-diamine was treated with sodium chloro-methylene-phosphonate in alkaline solution at reflux for three days. It was converted first to the lead salt with lead acetate and then to the free acid with hydrogen sulphide. The product was a colourless hygroscopic syrup which was very soluble in water, slightly soluble in alcohol and insoluble in ether. It was obtained as a glassy solid by dehydration under reduced pressure.

Potentiometric investigations of acid-base and metal-binding equilibria were carried out at 25° C. and 0·1 ionic strength with a Beckman Model *G* pH meter. The eight acid dissociation constants of the ligand were found to be 1·46, 2·72, 5·05, 6·18, 6·63, 7·43, 9·22 and 10·95. The equilibrium constants corresponding to the overlapping dissociation steps in each of the three buffer regions were determined by a graphical method. Because of the presence of two basic nitrogen atoms alpha to the acidic groups, the most acid form of the ligand is believed to be a double dipolar ion (I). If formula I is accepted, the presence of only two strongly acidic groups, corresponding to dissociation of hydrogen ions from neutral $—CH_2PO(OH)_2$ groups, becomes understandable. After the removal of two protons, there remain (formula II) four equivalent phosphonate hydroxyl groups which give rise to a long sloping buffer region involving four overlapping dissociation steps to form compound III. It is somewhat surprising that charge repulsion in III gives rise to a difference of only 1·7 pK units between the seventh and eighth dissociation constants. This may be due in part to the high negative charge of the anion, and to partial electrostatic binding of the ammonium hydrogens to the negative phosphonate oxygens.



The titration curves of the ligand in the presence of equimolar concentrations of metal ions given in Fig. 1 all indicate the formation of metal chelates containing as much as two hydrogen ions in addition to the metal. At higher pH all the acidic chelates go over to the 'normal' chelates from which all the dissociable hydrogens have been displaced. The copper (II) titration curve shows the sharpest break at eight moles of base per mole of ligand or metal, and indicates the formation of a metal chelate compound corresponding to formula IV. The titration curve of the iron (III) chelate compound shows partial hydrolysis of the normal chelate compound, indicating that at least one hydroxide ion becomes

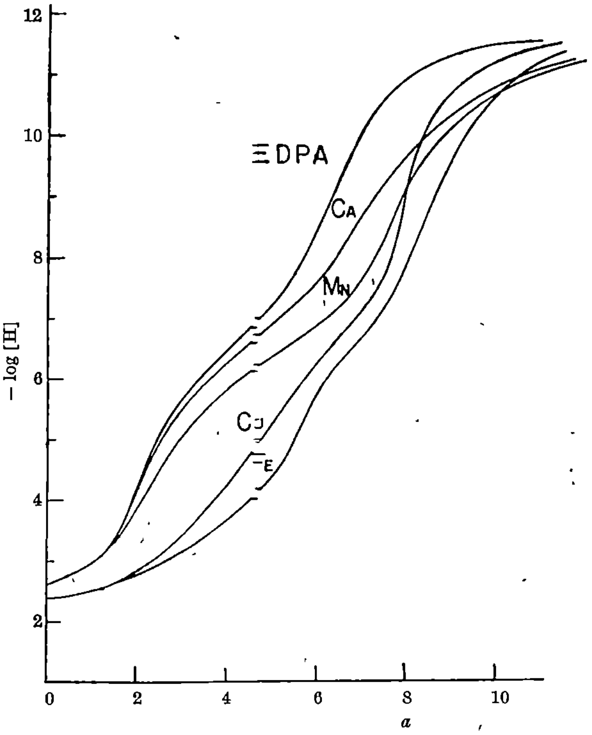


Fig. 1. Potentiometric titration of ethylene-diamine-tetra-methylene-phosphonic acid —log [H] vs. *a*, moles of potassium hydroxide added per mole of ligand

bound to the metal at high *p*H in spite of the large negative charge on the chelate compound. The logarithms of the normal chelate stability constants for combination of the metal ion with the octa-negative anion were calculated as: calcium (II), 6·09; manganese (II), 9·75; copper (II), > 10; and iron (III), > 10. It is apparent from the relative positions of the copper (II) and iron (III) titration curves that the chelate of the latter metal is considerably more stable. The stability is sufficiently high that a solution of the light yellow iron (III) chelate may be stored at a *p*H of about 11 for a number of months without developing any sign of the precipitation of ferric hydroxide. The apparent stability of the iron (III) chelate compounds in alkaline solution indicates possible usefulness as an iron carrier.

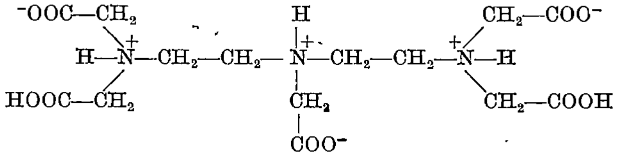
Polyaminopolycarboxylic Acids derived from Polyethyleneamines

THE effects of increasing length of the alkylene bridge on acid dissociation constants and metal chelate stability constants of homologues of ethylenediaminetetra-acetic acid derived from polymethylenediamines have been reported within recent years[1]. The effects of an increase in the polydentate and polyelectrolyte nature of polyaminopolycarboxylic acids derived from polyethylene polyamines have not been investigated except for a brief report on diethylenetriaminepenta-acetic acid[2]. An investigation of diethylenetriaminepenta-acetic acid and triethylenetetraminehexa-acetic acid was therefore undertaken because of their relationship to ethylenediaminetetra-acetic acid.

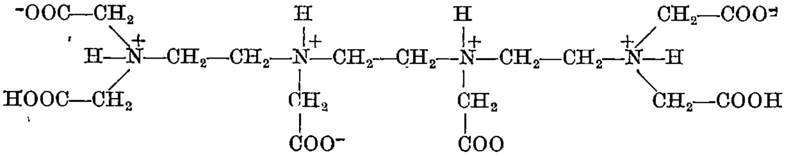
The acids were prepared by the reaction of diethylenetriamine and triethylenetetramine with sodium cyanide and formaldehyde under alkaline conditions according to the procedure of Bersworth[3]. The free acids were separated from the alkaline reaction products by means of the hydrogen form of 'Dowex-50' on a column process. Concentration of the eluate gave the acids as white crystals which were purified by recrystallization from a minimum volume of hot water.

The acid dissociation constants of diethylenetriaminepenta-acetic acid and triethylenetetraminehexa-acetic acid were determined from potentiometric data at 25° C. and 0·1 ionic strength (potassium nitrate) using a Beckman Model *G* *p*H meter. The equilibrium constants corresponding to the overlapping dissociation steps of the buffer regions were calculated by the graphical method of Schwarzenbach[4]. The acids are tri- and tetra-dipolar ions respectively having the formulæ:



$$(^{-}OOC-CH_2)(HOOC-CH_2)\overset{+}{N}H-CH_2-CH_2-\overset{+}{N}H(CH_2COO^{-})-CH_2-CH_2-\overset{+}{N}H(CH_2-COO^{-})(CH_2-COOH)$$

(I)



$$(^{-}OOC-CH_2)(HOOC-CH_2)\overset{+}{N}H-CH_2-CH_2-\overset{+}{N}H(CH_2COO^{-})-CH_2-CH_2-\overset{+}{N}H(CH_2COO)-CH_2-CH_2-\overset{+}{N}H(CH_2-COO^{-})(CH_2-COOH)$$

(II)

Neutralization of the pentabasic diethylenetri aminepenta-acetic acid occurs with one stron inflexion corresponding to formation of the tri potassium salt. Triethylenetetraminehexa-acetic acid a hexabasic acid, exhibits two inflexion points : weak inflexion occurring on the addition of three equivalents of potassium hydroxide and a well defined inflexion corresponding to the formation o the tetrapotassium salt.

The acid dissociation constants are listed in Table together with the values reported by Kroll[2] fo diethylenetriaminepenta-acetic acid.

Table 1. *pK* VALUES OF THE APPARENT IONIZATION CONSTANTS O DIETHYLENETRIAMINEPENTA-ACETIC ACID AND TRIETHYLENETETRA AMINEHEXA-ACETIC ACID AT 25° C. IN 0 1 M POTASSIUM NITRAT

Acid	pK_1	pK_2	pK_3	pK_4	pK_5	pK_6
DTPA	1·79	2·56	4·42	8·76	10·42	
DTPA[2]*	1·90	2·70	4·42	10·62	12·59	
TTHA	—	2·64	4 08	6 26	9 67	10 82

* Determined at 25° C. in 0 1 M potassium chloride

It appears that triethylenetetraminehexa-acetic acid is almost completely ionized at the concentration used in this study (approximately 3×10^{-4} M). Each compound possesses two strongly acidic carboxy groups (pK_1 and pK_2). The central ammonium groups are subject to the influence of the termina positively charged ammonium groups. The net result of this configuration with its relatively high positive potential is an increase in acidity of the central ammonium groups as reflected in the values of pK_3 for diethylenetriaminepenta-acetic acid and pK_3 and pK_4 for triethylenetetraminehexa-acetic acid.

The behaviour of the acids with various polyvalent metal ions is now under examination. The increase in metal chelate stability constants and the ability to enter into bimetallic chelate formation arising from the increase in polydentate character indicate utilization of these compounds as metal carriers and metal buffers.

Characterization of 17-Oxosteroids by Derivatives formed in the Zimmermann Reaction

DURING a study of 17-oxosteroid levels in blood plasma it was found that the amount of individual ompounds available was frequently too small to permit determination and also identification by paper hromatography. After the determination of isolated 7-oxosteroids by Zimmermann reaction it is possible o recover these compounds as derivatives which an be used for characterizing the compounds measured.
